elastic plate flexure: a central depression, deepest at the centre, which deepens and narrows with increasing time; and the development of a region of vertical uplift, a peripheral bulge, which in time migrates towards the basin.

The stress field also shows the basic elements of flexural response. At any given time it includes a plane of zero deviatoric stress separating regimes of horizontal extension and compression. The magnitude of the stress reaches a maximum at the surface or base of the mechanical lithosphere. Immediately after the onset of loading, stresses at the base of the lithosphere begin to relax and a region of effectively zero deviatoric stress develops. As time progresses this relaxed region grows upward, thereby concentrating stress in the upper lithosphere, a phenomenon which has also been observed in other geodynamic models[18,22]. The region of negligible deviatoric stress acts as the mechanical asthenosphere. Because of the strong temperature dependence of flow rates, the rate of upward concentration of stresses decreases with time, allowing the colder upper lithosphere to maintain stresses. This relaxation pattern is changed with an increase in heat flow and corresponding increase in temperature as seen in the 'hot lithosphere' model. The increase in temperature activates flow in the lower crust and, consequently, stresses are relaxed quickly in the lower crust as well as in the lower lithosphere. This second zone of relaxation forces the upper 15–20 km to carry the entire load. The rheology of the crust controls lithosphere response in high temperature regimes.

The flexural wavelength of the surface displacements is used to calculate an apparent elastic thickness (AET) at each point in time. This AET has been superimposed on the stress fields of Fig. 2 and approximately corresponds to the maximum depth to which deviatoric stresses are maintained. Given the logarithmic scales in Fig. 2, it seems that little change in the stress and displacement fields takes place at longer times, an observation which supports the validity of an elastic–plastic model approximation. However, the long term value of elastic thickness is not a simple function of temperature and, until the processes determining this value are understood, we retain the complete solution.

For use in predicting flexural parameters, our model results are summarized in Fig. 3*a*. Each contour gives the apparent

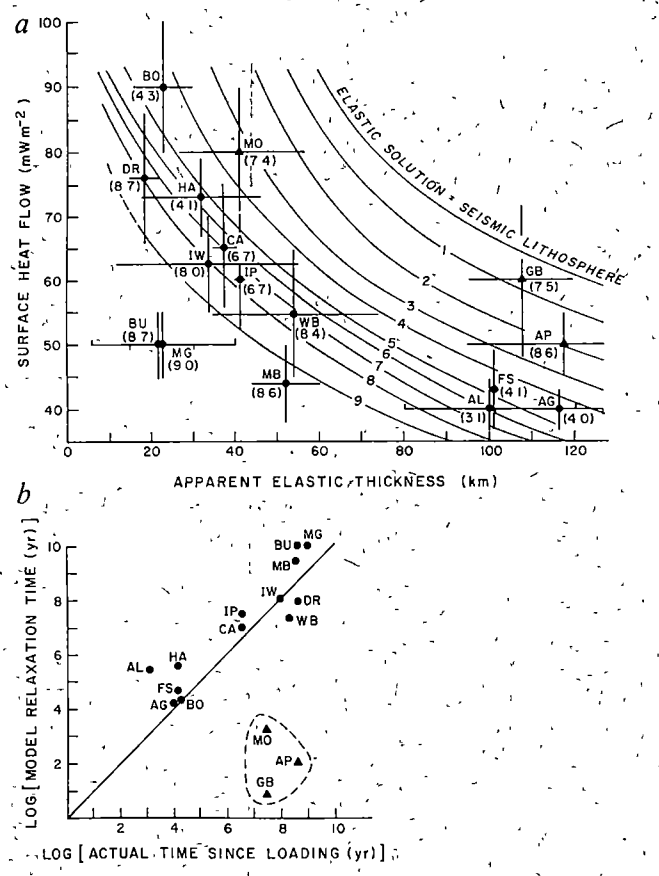

Fig. 3 *a*, Relaxation map relating apparent elastic thickness of a visco-elastic continental lithosphere to thermal state and loading time. Data and symbols from Table 1. Numbers in parentheses represent $\log_{10}$ (actual load duration in yr) for each site. Solid contour lines show the predicted weakening of the lithosphere with time after loading, caused by viscous stress relaxation in the lower and hotter part of the lithosphere; contour values are $\log_{10}$ (load duration in yr). Irregular contours result from lithosphere heterogeneity that affects the entire stress-relaxation process, and from numerical model interpolation. *b*, A comparison of the actual time since loading versus the visco-elastic model relaxation time necessary to produce the observed apparent elastic thickness. Model data are interpolated from relaxation map in *a*. Triangles are foreland basin sites in collision zones.

elastic thickness, as calculated from the visco-elastic model, for a given thermal state and a particular loading time. For example, a hot lithosphere characterized by surface heat flow of 90 mW m^{-2} (for example, Basin and Range) has an AET of 65 km for very short loading times (seismic lithosphere), which relaxes to <30 km in 10^4 yr (Lake Bonneville unloading) and would further relax to an AET of 15 km were the load and the same thermal state to exist for 10^8 yr. In contrast, an intermediate 'warm' lithosphere characterized by surface heat flow of 60 mW m^{-2} starts out with a seismic lithosphere of 125 km, relaxes to an AET of 50 km in 10^6 yr after loading and to an AET of 38 km after 10^8 yr. We have also superimposed on this relaxation map (Fig. 3*a*) the flexure data from Fig. 1. Included with each data point is the age (duration) of the load. There is general agreement between actual load duration and model relaxation time necessary to reach the observed AET at a given thermal state, as shown by the near one-to-one correspondence in Fig. 3*b*, despite large uncertainties in both thermal and flexure data and the sensitivity of the relaxation map to model parameters. The fit in Fig. 3 is surprisingly good considering that the relaxation contours in Fig. 3*a* were calculated from models with general loading conditions and flow properties and a simple thermal model. Furthermore, as this relaxation model was constructed from steady-state thermal models, we would expect to fit only those data for which the thermal state has not changed appreciably since loading. For those data with long or complex thermal histories large errors in model fit could exist.

This is probably the case with the foreland basin data (MO, AP, GB), which depart dramatically from model predictions and misfit the model in Fig. 3. The lithosphere flexure in continental collision zones is the result of complex thermal and mechanical processes which apparently are not simulated by this model. It is less likely, but also possible, that heat-flow determinations surrounding foreland basins are systematically biased. The oldest loads (BU, MG, MB) have had a greater opportunity to experience transient thermal effects and so are more likely not to fit this steady-state model. This may be the case, but is obscured by the logarithmic scales in Fig. 3.

Our analysis of continental flexure data together with heat-flow data produces the following conclusions: (1) The application of oceanic lithosphere thermal and thermo-mechanical models to continental lithosphere does not seem to be supported by heat-flow and continental flexure data. In particular the oceanic lithosphere correlations between heat flow and age and between elastic thickness and a specific temperature range are not observed on continents. (2) Complete time-dependent solutions for visco-elastic lithospheric flexure with thermally activated flow properties can be obtained numerically, the principal free parameters being temperature and rheological properties. Generic visco-elastic mechanical models of a vertically heterogeneous lithosphere incorporating simple steady-state thermal models can explain most observed flexural parameters. Those data that are not well fit by the model have long or complex thermal or mechanical histories. An understanding of both is critical when considering the long-term behaviour of continental lithosphere.

We thank the Alexander von Humboldt Foundation (DSC) and the Deutscher Akademischer Austauchdienst (SDW) for support and the University of Utah Research Committee for financial assistance.

Lateral transport of Mn in the north-east Pacific Gyre oxygen minimum

J. H. Martin & G. A. Knauer

Moss Landing Marine Laboratories, Moss Landing, California 95039, USA

Accurate measurement of the concentration and fluxes of a wide range of dissolved and particulate materials in the water column is need to quantify the global cycling of heat, water and chemical constituents[1]. An important aspect of any Global Ocean Flux study is the lateral transport of materials at basin or global scales; to study lateral transport, useful tracers of water-mass movements must be identified. Here we report that Mn is rapidly removed (-0.027 μmol m^{-3} yr^{-1}) from the north-east Pacific Gyre dissolved-Mn maximum onto biogenic particles sinking through the oxygen minimum (500–1,100 m). To support removal, dissolved Mn must be supplied within the oxygen minimum at net advective horizontal transport rates of ~0.6–0.9 cm s^{-1}. The high affinity of dissolved Mn for particles, together with the readily discernible differences in inshore/offshore dissolved distributions, indicate that Mn is a chemical tracer with great potential in future studies of large-scale circulation processes in the ocean[1].

We show dissolved and suspended particulate Mn distributions observed 830 km north of the Hawaiian Islands (28°N; 155°W), together with temperature, salinity and dissolved oxygen data, in Fig. 1. Dissolved-Mn concentrations were relatively high (0.8 nmol kg^{-1}) in near surface waters, then decreased steadily until a minimum (~0.2 nmol kg^{-1}) was reached at depths of 200–450 m (probably originally subarctic surface waters). Dissolved Mn began increasing concomitantly with rapidly decreasing oxygen concentrations in the 450–700-m depth interval. After reaching a maximum of 0.54 nmol kg^{-1} at 700 m, concentrations decreased to 0.34 nmol kg^{-1} at 1,000 m. With the exception of two relatively high values observed at 1,090 m (0.55 nmol kg^{-1}) and 1,420 m (0.40 nmol kg^{-1}), amounts of dissolved Mn remained fairly constant (0.24–0.29 nmol kg^{-1}) for the remainder of the 2,090-m water column sampled. These data were obtained using GoFlo-bottle sampling, Chelex-100 ion-exchange preconcentration and atomic absorption analytical procedures that are described in detail elsewhere[2].

In addition to the dissolved amounts, two fractions of suspended particulate Mn were also measured: weakly leachable (LE, that dissolved with 25% acetic acid)[3]; and that remaining after leaching (RE, the refractory portion, dissolved via Teflon bomb digestion)[4]. The latter is believed to be that locked into aluminosilicate lattices and, as expected, amounts were extremely low (0.2–5.9 pmol kg^{-1}) in these remote gyre waters far removed from continental land masses (Fig. 1). Particulate LE Mn concentrations were very low (4–9 pmol kg^{-1}) in the upper 140 m of the water column (Fig. 1). More or less steadily increasing values were found from 140–600 m, followed by a minimum at 900 m, a secondary maximum at 1,090 m and steadily decreasing concentrations thereafter.

Because free-floating particle traps[5] were also used during this study (deployed for 33 days), flux data are available to determine whether Mn was being regenerated from (decreasing fluxes with depth), or scavenged onto (increasing fluxes with depth), particles sinking through the oxygen minimum. The dramatic increases in Mn fluxes (Fig. 2) indicate, in view of the following considerations, that dissolved Mn was being removed onto particles. Increases in total flux did not result from the lateral transport of aluminosilicate phases because RE Mn fluxes remained uniformly low and constant (2–3 μmol m^{-2} yr^{-1}) throughout the 2,000-m water column (Fig. 2). Furthermore, the RE Mn fluxes were similar to atmospheric air/sea Mn fluxes (3.3 μmol m^{-2} yr^{-1}) estimated by Duce at Eniwetok[6], and we assume that this was the primary source of the aluminosilicate (that is, RE) Mn in our traps.

Trapped exchangeable (TE, that dissolved in the particle trap cyclinders)[2,7,8] Mn fluxes were also fairly constant with depth (14–20 μmol m^{-2} yr^{-1}), though they were an order of magnitude greater than the RE Mn fluxes. Clearly then, the fraction responsible for the dramatic increase in total Mn fluxes between 500 and 1,000 m was the LE fraction (Fig. 2). This flux increase could result from *in situ* scavenging of dissolved Mn or from the advective lateral transport of particles already rich in LE Mn. Comparisons of suspended particulate LE Mn and trapped particulate LE Mn concentrations (Fig. 1) indicate that the trapped particles are remarkably different from those in suspension (at least judging by their Mn content) for most of the water column; that is, Mn concentrations are not equivalent in the two classes of particles until depths of 900 m are reached. Thus, we conclude that the increase in flux does indeed result from the *in situ* removal of dissolved Mn onto biogenic particles sinking through the O_2 minimum/Mn maximum.

Assuming steady-state conditions, this removal of dissolved Mn must be balanced by input processes of some kind. To define the importance of various input mechanisms, we used a simple 500–1,100-m box model shown in Fig. 3. The model illustrates the following: (1) Mn removed from the box by particle scavenging at a rate of -0.027 μmol m^{-3} yr^{-1} (500-m(LE+TE)Mn flux minus the 1,100-m(LE+TE) Mn flux divided by 1,100 − 500 m = 600 m) would be completely removed in 16 yr because the average integrated Mn concentration in the box is only

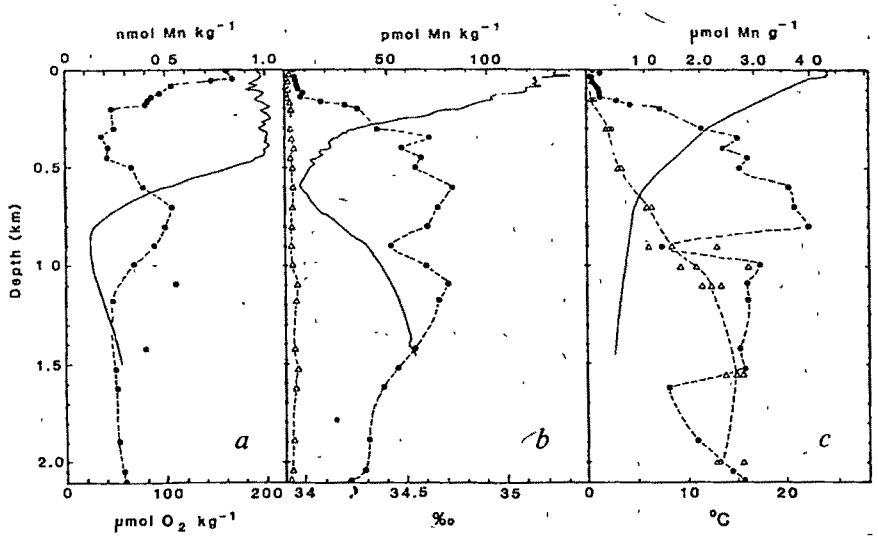

Fig. 1 Manganese and hydrographic measurements made 830 km north of Hawaii (28°N; 155°W) in July/August of 1983: *a*, dissolved Mn (-●--) and oxygen (—); *b*, suspended particulate leachable (-●--) and refractory (-△--) Mn with salinity (——); *c*, suspended (-●--) and trapped (-△--) particulate Mn concentrations on a gram-dry-weight basis, together with temperature (——) data.

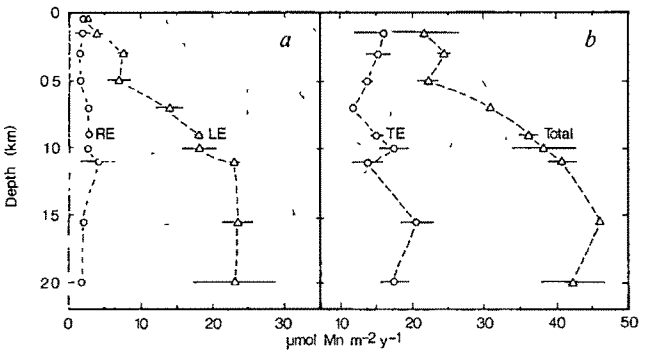

Fig. 2 Manganese fluxes measured with particle traps at 28°N, 155°W *a*, particulate refractory (RE) Mn (-○- -) and particulate leachable (LE) Mn (-△- -); *b*, trapped exchangeable (TE, Mn dissolved in trap solutions) (-○- -) and total Mn fluxes (-△- -). Means and standard deviations ($n=3$) are shown for all depths except 700 m (LE, $n=2$, range is shown, TE and total, $n=1$). Standard deviations for the refractory portions were usually smaller than the symbols used; 50-m TE and total fluxes are not shown because of possible zooplankton swimmer[5] contamination.

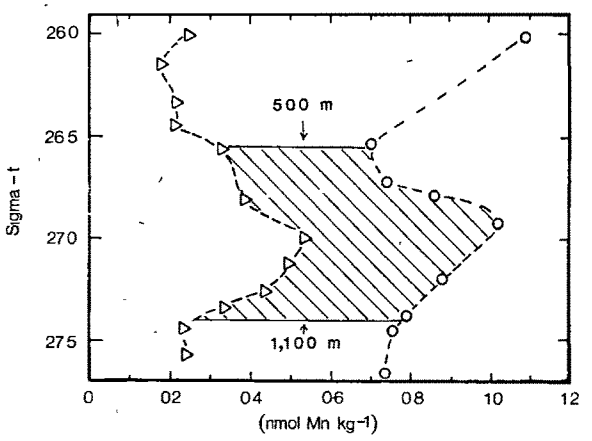

Fig. 4 Dissolved Mn versus density (σT) north of Hawaii (Δ 28°N, 155°W) and west of California (○ 36.5°N, 123°W). Hatched area represents Fig. 3 box model based on Hawaii depth-versus-σT relationship.

0.42 μmol m^{-3}. (2) The shape of the dissolved-Mn profile (Figs 1, 3) shows that vertical advective/diffusive processes cannot be re-supplying the Mn removed by scavenging. Dissolved Mn advecting upward into the box at 1,100 m is balanced by Mn advected upward out of the box at 500 m because the concentrations at 500 and 1,100 m are about the same and there is no reason to believe that vertical advection rates would be markedly different at these depths (for example, we use a velocity of 4 m yr^{-1} at both depths)[9]. (3) It is also apparent that diffusive mixing processes are removing Mn from, rather than supplying Mn to, the box; $\Delta Mn/\Delta z$ calculations from 400–600 m and 1,000–1,200 m result in an upward Mn flux of 5 μmol m^{-2} yr^{-1} across the 500-m top of the box and a downward flux of 4 μmol m^{-2} yr^{-1} across the 1,100-m bottom of the box when a global ocean average eddy diffusivity constant of 1.7 cm^2 s^{-1} is used[10]. (4) Adding up the total vertical fluxes into (22 μmol m^{-2} yr^{-1}) and out of (−47 μmol m^{-2} yr^{-1}) the box results in a difference of 25 μmol m^{-2} yr^{-1} that must be supplied by horizontal advective/diffusive processes to maintain steady-state conditions.

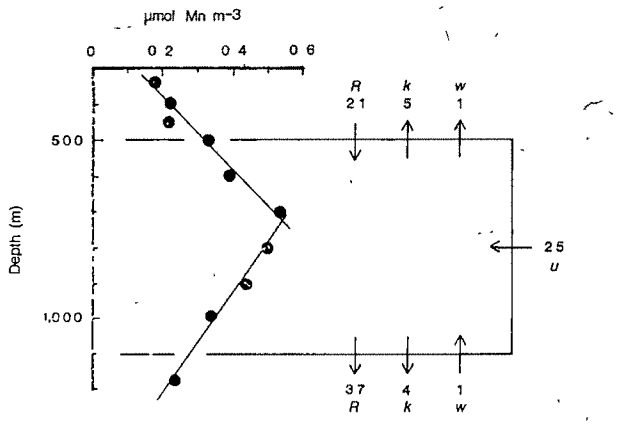

Fig. 3 A box model for the 500–1,100-m depth interval with fluxes (arrows) in units of μmol Mn m^{-2} yr^{-1}. Dissolved Mn versus depth regressions shown on the left side yielded equations of μmol Mn m^{-3}. $= -0.18 + 0.0010$ (m) for the upper line ($r = 0.9758$; $n = 6$) and $= 1.05 - 0.0007$ (m) for the lower line ($r = 0.9890$; $n = 5$) Vertical diffusive fluxes (k) were estimated using these slopes and an eddy diffusivity coefficient of 5,400 m^2 yr^{-1} (1 7 cm^2 s^{-1}). Vertical advective fluxes (w) across 500 and 1,100-m boundaries were estimated by multiplying Mn concentrations by a vertical advective rate of 4 m yr^{-1} Particulate associated (LE + TE) Mn flux data (R) are from Fig 2. The lateral flux (u) was estimated from the difference (total fluxes out of box minus total fluxes into box).

We believe that the source of the Mn being removed in the north-east Pacific Gyre is provided by Mn regeneration[2,7,11,12] along continental margins. For example, dissolved-Mn profiles measured off California[13] are remarkably similar in shape to those measured in this study, when they are compared with sigma-t (σT) data (see Fig. 4). Concentrations are also significantly higher inshore, which must be so if onshore/offshore lateral transport arguments are to be used.

We have no evidence that the Mn in the gyre indeed originated off the west coast of the United States. However, assuming that inshore Mn concentrations along other north Pacific continental margins are about the same as those we show in Fig. 4 and that the distance from California Station to the gyre station is representative (3,150 km), we can make first-order transport estimates assuming that $\Delta Mn/\Delta t = (\Delta Mn/\Delta x)u$, where $\Delta Mn/\Delta t$ is the combined average removal of dissolved Mn from the 500–1,100-m box by particulate scavenging and vertical mixing processes (−25 μmol m^{-2} yr^{-1} − 600 m = −0.042 μmol m^{-3} yr^{-1}); $\Delta Mn/\Delta x$ is the average difference between inshore and offshore dissolved-Mn concentrations in the oxygen minimum (0.46 μmol m^{-3}, from Fig. 4) divided by the distance (3.15×10^6 m) between the two locations; and u is the resulting net advective velocity in units of m yr^{-1}.

Using these estimates, the net advective velocity necessary to support Mn removal within the oxygen minimum off Hawaii is 290,000 m yr^{-1} or 0.9 cm s^{-1}. Based on particulate scavenging rates alone (ignoring vertical mixing processes), the estimates become 180,000 m yr^{-1} or 0.6 cm s^{-1}. Thus, the average length of time required to transport the dissolved Mn from California to Hawaii would be ~10–20 yr.

Clearly, the net advective transport rates presented above are crude first estimates. We considered Mn transport only along the x and z axes, but dissolved Mn may be gained or lost by lateral mixing processes along the y axis as well. Nevertheless, with appropriate expansion of the water column and particle-trap sampling grid, and the simultaneous measurements of other trace elements that are removed in the open ocean (for example, J.H.M. and G.A.K., in preparation) or along continental margins (for example, Ag, Cu)[14] as well as radionuclides (^{210}Pb, ^{231}Pa, ^{230}Th)[15,16], we believe that the use of these chemical tracers will result in a significant gain in the understanding of global ocean circulation processes.

Finally, we believe that the primary processes responsible for the excess Mn accumulating on the sea floor[17,18] are the combination of continental weathering input, dissolved-Mn lateral transport and sinking biogenic particle scavenging output. Although

we have presented these arguments before in descriptions of research performed at pronounced oxygen minimum[2,8] and/or nearer the shore[7,19], final proof required the strong evidence provided here of at depth lateral transport and significant particulate scavenging of dissolved Mn at an open ocean location.

We thank M. Gordon, S. Fitzwater, C. Hunter and S. Tanner for their help with the field and laboratory work and W. Broenkow for the hydrographic data. This research was supported by grants from the NSF Marine Chemistry Programme (VERTEX OCE 82-16670 and OCE 82-16671).

Sr isotope composition of sea water over the past 75 Myr

M. R. Palmer*† & H. Elderfield‡

* Department of Earth Sciences, University of Leeds, Leeds LS2 9JT, UK
‡ Department of Earth Sciences, University of Cambridge, Cambridge CB3 0EZ, UK

The $^{87}Sr/^{86}Sr$ ratio of ancient seawater, as recorded in marine carbonates, is an important tracer of long-term variations in ocean chemistry[1-5]. However, the Sr isotope balance of the oceans has been difficult to constrain; consequently, attempts to evaluate the temporal $^{87}Sr/^{86}Sr$ changes have been largely qualitative. To constrain the causes of these variations we have measured $^{87}Sr/^{86}Sr$ ratios in carefully cleaned unrecrystallized foraminifera from DSDP sites 21 and 357. The data presented here have been quantitatively modelled taking advantage of recent advances in understanding of the Sr geochemical cycle. They suggest that whereas hydrothermal fluxes and carbonate recycling are of major importance in defining the marine $^{87}Sr/^{86}Sr$ ratio, the major control over its variations through the Cenozoic has been changes in the isotope composition of Sr derived from the weathering of silicate rocks.

Previous studies have suggested that the major controls over variations in the marine $^{87}Sr/^{86}Sr$ ratio are: (1) the proportions of oceanic Sr derived from crustal (mainly granitic) and mantle (continental basalts and hydrothermal input) sources; (2) the rate of transport of Sr from the continents to the oceans; and (3) recycling of Sr from marine carbonate sediments[2,5-9]. Two factors require that these ideas and the data behind them be re-examined. First, an increased understanding of the magnitude of the hydrothermal processes at ocean ridges allows greater constraints to be placed on the oceanic Sr isotope balance[10-13]. Second, a recently-produced Sr isotope curve for seawater shows more fluctuations through time than were previously thought to be present[1].

† Present address Department of Geology and Geophysics, Yale University, New Haven, Connecticut 06511, USA

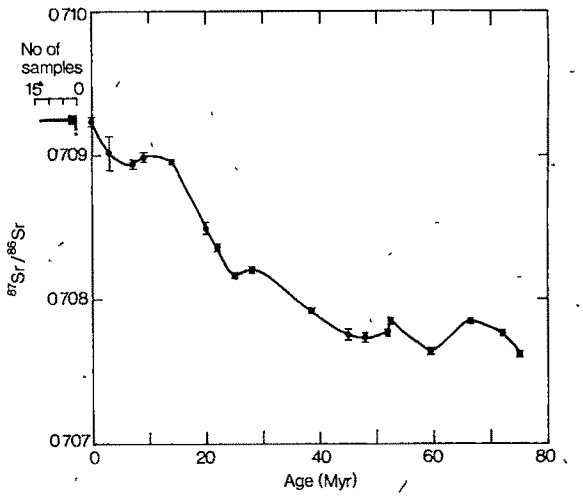

Fig. 1 Marine $^{87}Sr/^{86}Sr$ ratio since 75 Myr BP. Histogram is for 22 modern samples. National Bureau of Standards 987 $SrCO_3$ $^{87}Sr/^{86}Sr = 0.710275$, Eimer and Amend $SrCO_3$ $^{87}Sr/^{86}Sr = 0.708066$.

The results of this study are shown in Fig. 1 and Table 1. The form of the curve is in good agreement with the recently produced Burke curve[1]. A further aspect of Fig. 1 is that it seems probable that the seawater Sr isotope curve can be constrained to a higher precision than is implied by the earlier studies through careful sample selection and cleaning. This considerably strengthens the potential of the curve for stratigraphical correlation and absolute age determinations during periods showing the greatest rates of change of $^{87}Sr/^{86}Sr$ ratios (4×10^{-5} Myr^{-1}). Measurements of 24 Recent foraminifera samples (see histogram in Fig. 1) are identical to within 2.6×10^{-5} (2σ), indicating a notional resolution of ± 0.65 Myr (the practical limit of resolution is about ± 1.5 Myr). Thus, temporal variations in marine $^{87}Sr/^{86}Sr$ ratios can provide a high-resolution dating and palaeostratigraphical method for the Oligocene-Recent, with potential for other periods as well.

To examine the various processes that may control the marine $^{87}Sr/^{86}Sr$ curve, a model was constructed based on the marine geochemical cycle of Sr shown in Fig. 2. In the model, the major flux of dissolved Sr to the oceans is from river input, ~75% of which is derived from weathering of uplifted limestones with the remainder resulting from the weathering of silicate rocks[5,14]. Recycling also takes place through pore-water Sr diffusing into bottom waters from carbonate-rich sediments; a smaller flux is associated with sediments depleted in carbonate[15]. Sr isotope exchange takes place between basalt and seawater during circulation of seawater through fast-spreading mid-ocean-ridge hydrothermal systems[7-9]; no significant Sr mass transfer has been observed during this process. Neither Sr isotope exchange nor mass transfer is observed during lower temperature ridge-flank hydrothermal circulation[11] and the only significant sink for Sr in the modern oceans is biogenic calcium carbonate.

The present-day Sr fluxes are given in Fig. 2. Two values are given for the hydrothermal flux because of uncertainties over the proportions both of advective and convective heat flow at mid-ocean ridges and of advective heat loss associated with high-temperature ridge crest versus low-temperature ridge flank hydrothermal systems[13,16-18]. One value is derived from linking chemical data in hydrothermal vents with global heat and ^3He loss from the ocean crust[10-19]; the second value acknowledges the conclusions from recent geophysical and geochemical work (mass balance of alkalis and alkaline earths, Li in basalts, Ge/Si ratios) that the hydrothermal flux at ridge axes is considerably lower than originally estimated[12,13,20-23]. Although several studies have been made of the Sr isotope composition of river water[4,5,24], these have been limited to a few of the world's major rivers; a latest estimate from Canadian rivers[24], however, does suggest that the global average is likely to be ~0.711. By solving

Table 1 $^{87}Sr/^{86}Sr$ and Sr/Ca ratios in foraminiferal calcite from DSDP sites 21 and 357

21	128	75	0.707618±17	1.36

the steady state equations (see Fig. 2) for the riverine Sr isotope composition, using the data in Fig. 2, we obtain $^{87}Sr/^{86}Sr$ ratios of 0.7119 and 0.7102 (for the two different hydrothermal fluxes), both similar to the above value. However, the ratio required to balance the low hydrothermal flux yields a $^{87}Sr/^{86}Sr$ ratio for silicate weathering (0.7173) that is significantly closer to the average Sr isotope composition of aluminosilicate detritus in oceanic core top sediments (0.7166)[25] than does the ratio based on the high hydrothermal flux (0.7243).

Next, we considered temporal variations in the fluxes shown in Fig. 2. Oceanic crustal production rates are generally thought to have been higher 75 Myr BP than today[26,27]. If we assume that the hydrothermal flux is directly proportional to seafloor spreading rate[28], then variations in the hydrothermal Sr flux can be calculated. Three estimates of seafloor spreading rates were considered here: rates that were 60% higher 65 Myr BP than today[29], rates that were a maximum of 25% higher 75 Myr BP than today[30] and an intermediate rate[31] (corrected for subduction).

Because of the high concentration of Sr in marine carbonate, recycling of Sr from the weathering of uplifted limestones and diffusion of Sr from carbonate-rich sediment pore waters play an important part in the Sr marine geochemical cycle. From the mass half life of continental limestones[14] and the $^{87}Sr/^{86}Sr$ ratio of ancient seawater, Brass[5] calculated the average $^{87}Sr/^{86}Sr$ ratios derived from the weathering of uplifted limestones at intervals over the past 400 Myr. The $^{87}Sr/^{86}Sr$ ratio of pore waters diffusing into overlying waters from carbonate-rich sediments is equivalent to that of 18-Myr BP seawater[15]. Thus, similarly to Brass, we calculated the average $^{87}Sr/^{86}Sr$ ratio of this source against time.

The effects of carbonate recycling and varying hydrothermal fluxes on the marine $^{87}Sr/^{86}Sr$ ratio since 75 Myr BP, obtained by these methods, are shown in Fig. 3*a*. It is clear that these two controls cannot fully explain the observed Sr isotope variations. Moreover, the consequence of assuming the most rapid variations in spreading rates[29] is that they produce unrealistically high global atmospheric CO_2 levels, temperatures and sea levels 75 Myr BP[32] and, as noted above, recent evidence suggests that hydrothermal fluxes are lower than originally supposed. Hence, changes resulting from fluctuations in hydrothermal activity as well as from carbonate recycling appear to be minor. Thus, variations in the nature of the riverine Sr flux to the oceans must be a major control on temporal variations in the seawater $^{87}Sr/^{86}Sr$ ratio.

The lower $^{87}/^{86}Sr$ ratios in the past have been ascribed to lower river fluxes because of the decreased land area at that time[7,14]. However, the rate of continental weathering is a complex function of climatic and geographical variables[33]. Indeed, global CO_2 models suggest that the rate of weathering per unit area of continent was considerably higher 75 Myr BP than today because of the interplay of these factors[32]. It is likely, therefore, that the riverine Sr flux was at least equal to or higher than its present-day value. Thus, the low observed marine $^{87}Sr/^{86}Sr$ ratios relative to the model values (Fig. 3) must reflect one or more of the following factors: a higher internal/external continental drainage ratio 75 Myr BP; decreases in the proportion of Sr derived from the weathering of limestones since 75 Myr BP; increases in the average $^{87}Sr/^{86}Sr$ ratio derived from the weathering of silicate rocks since 75 Myr BP.

The increase in land area since 75 Myr BP[34] requires extreme assumptions to be made for a concurrent fall in the continental internal/external drainage ratio. The Sr derived from limestone weathering would have to have been 10 times higher than that now to account for the smallest model deviation from the observed marine $^{87}Sr/^{86}Sr$ ratios at 75 Myr BP (assuming a constant Sr flux magnitude and ratio from silicate weathering). Clearly, this mechanism alone cannot realistically account for the model deviations. These two arguments strongly suggest that

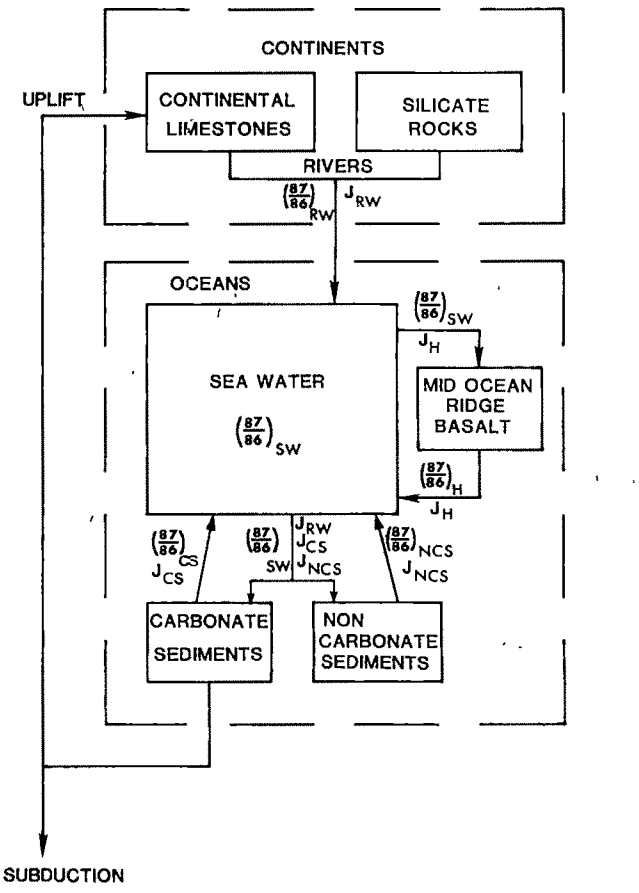

Fig. 2 Marine geochemical cycle of Sr. (J = flux; (87/86) = $^{87}Sr/^{86}Sr$ ratio of flux.) At steady state: $[87]_{SW} = ([87]_{RW}J_{RW} + [87]_H J_H + [87]_{CS}J_{CS} + [87]_{NCS}J_{NCS})/(J_{RW} + J_H + J_{CS} + J_{NCS})$; $[86]_{SW} = ([86]_{RW}J_{RW} + [86]_H J_H + [86]_{CS}J_{CS} + [86]_{NCS}J_{NCS})/(J_{RW} + J_H + J_{CS} + J_{NCS})$; where SW = seawater, RW = river water, H = hydrothermal isotope exchange, CS = carbonate sediment pore waters, NCS = non-carbonate sediment pore waters. Magnitudes of present-day fluxes (mol yr^{-1}) are: $J_{RW} = 2.5 \times 10^{10}$ (ref. 37), $J_{NCS} = 4.0 \times 10^8$ (ref. 15), $J_{CS} = 3.0 \times 10^9$ (ref 15), $J_H = 1.2 \times 10^{10}$ (ref. 10) $= 0.38 \times 10^{10}$ (ref. 11). $^{87}Sr/^{86}Sr$ ratios of present-day fluxes are: $(87/86)_{NCS} = 0.7064$ (ref 15), $(87/86)_{CS} = 0.7087$ (ref. 15), $(87/86)_H = 0.7040$ (refs 8, 9), $(87/86)_{SW} = 0.70924$ (this work). Sensitivity of model to uncertainties in above values; resulting uncertainty in calculated $(87/86)_{SW}$ is 2×10^{-4} for uncertainty in J_{RW} and 1.4×10^{-4} for uncertainty in $(87/86)_H$; all other variables produce negligible uncertainties in $(87/86)_{SW}$ or are considered in the text.

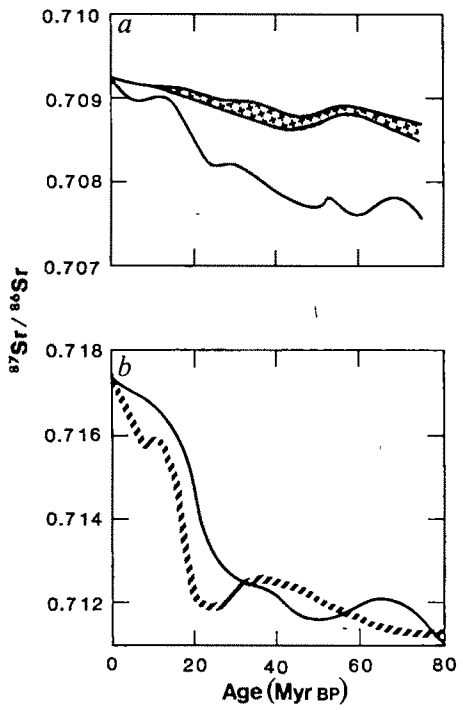

Fig. 3 *a*, Variations in the marine $^{87}Sr/^{86}Sr$ ratio due to changes in rates of hydrothermal activity and carbonate recycling. Results using an intermediate rate of change in J_H (ref. 31) are shown (high and low rates of change in J_H (refs 29, 30) show similar patterns). The shaded area gives the range in $^{87}Sr/^{86}Sr$ ratios calculated from high and low values of J_H (refs 10, 11) and the bottom curve shows the measured values of $^{87}Sr/^{86}Sr$ for sea water The model curves were calculated at 10-Myr intervals. *b*, Variations in the $^{87}Sr/^{86}Sr$ ratio derived from the weathering of silicate rocks: the shaded area shows qualitative variations in glacial intensity (after Armstrong[6])

changes in the $^{87}Sr/^{86}Sr$ ratio derived from the weathering of silicate rocks must play a dominant role in varying the marine $^{87}Sr/^{86}Sr$ ratio.

Figure 3*b* shows the changes in silicate $^{87}Sr/^{86}Sr$ ratios (at a constant riverine flux magnitude) required to produce the observed marine $^{87}Sr/^{86}Sr$ ratios, assuming a low hydrothermal flux and smaller changes in seafloor spreading rates. The most notable feature of the curves in Fig. 3*b* is the sharp rise in $^{87}Sr/^{86}Sr$ ratios from 25 Myr BP to the present, with relatively constant Sr isotope ratios before this time. This feature correlates well with two important variables in geological history. First, the similarity to the qualitative curve of glacial activity over the past 75 Myr BP is striking, providing some circumstantial support for Armstrong's[6] hypothesis that increased glacial action has affected the marine $^{87}Sr/^{86}Sr$ ratio by both exposing and increasing the weathering rates of ancient shield areas; these terrains have high $^{87}Sr/^{86}$ ratios[35]. Second, there is overwhelming evidence to suggest that during the late Cretaceous and early Cenozoic total worldwide volcanism was greater than at any subsequent time (see, for example, ref. 36). The past 30 Myr are marked by the Alpine and Himalayan orogenies. These widespread folding events resulted in the uplifting and accelerated erosion of rocks characterized by high $^{87}Sr/^{86}Sr$ ratios. Thus, the rise in the $^{87}Sr/^{86}Sr$ ratio derived from silicate weathering since 25 Myr BP may reflect a recovery from the previous era when weathering of young basaltic volcanics was more dominant.

We conclude, therefore, that whilst hydrothermal fluxes and carbonate recycling are of great importance in determining the absolute value of the marine $^{87}Sr/^{86}Sr$ ratio at any one instant, the major control over the variations in the ratio over the past 75 Myr has been changes in the isotope composition of Sr derived from silicate rock weathering.

We thank colleagues at Cambridge, Leeds and Yale, those associated with DSDP programme and J. Veizer for his review. This research was supported by NERC studentship GT4/80/GS/45 (M.R.P.) and grant GR3/4444 (H.E.). Cambridge Earth Sciences Series, contribution no. 541.

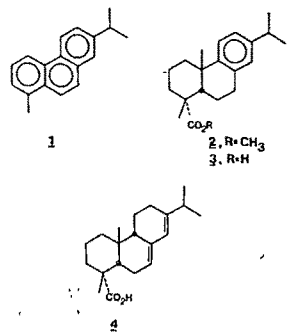
Pine wood origin for pitch from the *Mary Rose*

R. P. Evershed, K. Jerman & G. Eglinton*

Organic Geochemistry Unit, School of Chemistry, University of Bristol, Cantock's Close, Bristol BS8 1TS, UK

The raising of the wreck of King Henry VIII's flagship (AD 1509–45), the *Mary Rose*, from the bed of the Solent was a unique event, notable as a significant technical achievement in naval architectural history and as a source of well-preserved Tudor relics. Preservation is attributed to the anaerobic environment prevailing within the sediment during much of the period of burial and, in some cases, to the large quantities of pitch that permeated the ship and many of the relics. Although the function of many relics is usually easily recognized, their means of construction and the nature and origin of the materials used in their manufacture are often much less obvious. We report here the chemical analysis of six samples of pitch from the *Mary Rose*. Computerized gas chromatography/mass spectrometry (CGC/MS) and infrared spectroscopy have been used to 'fingerprint' the pitches and compare them with modern-day tars and pitches derived from wood, coal, peat and petroleum. Diterpenoid hydrocarbons, methyl dehydroabietate and dehydroabietic acid were found in similar proportions to 'Stockholm tar (good-quality pine tar obtained by the destructive distillation of *Pinus sylvestris*), so providing conclusive evidence for the derivation of the *Mary Rose* pitches from pine wood.



* To whom correspondence should be addressed

Until recently, chemical archaeological investigations have been concerned largely with the inorganic components of, for example, building materials, pottery, coins and weapons[1]. This apparent bias towards inorganic materials probably arises from their greater likelihood of survival over archaeological time compared with organic substances. Many inorganic materials remain largely unchanged after tens or even hundreds of years of weathering, whereas organic-based plant and animal products are rapidly decomposed unless protected from the degradative effects of moisture, oxygen and sunlight.

Historically, the use of tars and pitches as protective hydrophobic coatings is well established. However, to our knowledge no detailed chemical investigations have been performed to determine the origins or means of manufacture of such materials. Related organic chemical archaeological studies include GC analysis of animal fats from peat bogs and Eskimo dwelling sites[2,3], plant and animal residues from caves and pottery[4], a ^{13}C-NMR investigation of non-metallic seals[5], an infrared study of tar from a thirteenth century Norwegian shipwreck[6] and investigations of natural resins of art and archaeology, including GC and GC/MS studies[7,8].

Six samples of pitch and pitch-impregnated materials from the *Mary Rose* were selected for analysis. These included pitch from barrels found in the hold, 'luting' from the main deck, caulking from between the timbers of the outer frame of the ship, tarred anchor cable and a tarry solid (probably intrusive) found in a box of longbows. Table 1 lists these samples and their reference numbers.

GC and GC/MS analysis of the components of the *Mary Rose* pitches eluting in hexane, toluene and dichloromethane (DCM), and those obtained by esterification of the acid fraction, revealed in every case relatively simple mixtures of compounds. The hexane-eluting components of the pitch from the barrels produced the most complex patterns (Fig. 1*a*, *b*), with eight components comprising >90% of the total volatile components (calculated by integration of the reconstructed ion current (RIC) peak areas). The mass spectra of components 1–8 in Fig. 1 displayed molecular ions (M^+) at m/z 256 ($C_{19}H_{28}$), 254 ($C_{19}H_{26}$), 256 ($C_{19}H_{28}$), 252 ($C_{19}H_{24}$), 238 ($C_{18}H_{22}$), 220 ($C_{17}H_{16}$), 234 ($C_{18}H_{18}$) and 248 ($C_{19}H_{20}$), respectively. Comparison of these with reference spectra[9] indicated that the compounds were alkyl-substituted tricyclic diterpenoid hydrocarbons, the major component (peak 7 in Fig. 1) being retene (compound 1).

1 2 3 4

Further GC/MS analyses revealed the presence of methyl dehydroabietate (compound 2, m/z 314, $C_{21}H_{30}O_2$) as the major (>80%) ester component of the LC fractions from the *Mary Rose* samples. This latter compound was also the major constituent (>90%) of the methylated acid fraction, indicating that the principal acid is dehydroabietic acid (compound 3).

Diterpenoid compounds of this type have long been known to be major constituents of conifer resins[10,11], hence these CGC/MS data provide conclusive evidence that the *Mary Rose* pitches were produced from pine trees. As such compounds are not appreciably observed in peat and coal tars or petroleum bitumens, these can be discounted as potential sources. GC and CGC/MS of fractionated Stockholm tar produced a very similar distribution of hydrocarbons (Fig. 1*c*) to those of the barrels of pitch from the *Mary Rose*. Methyl dehydroabietate was also the major ester constituent and dehydroabietic acid again the major component of the acid fraction.

Table 1 *Mary Rose* tars and pitches and other materials

Sample	Appearance and odour	Origin
'Tarred' rope (MR AC)	20 strands 0.5–20 cm long, impregnated with tar	Anchor cable
'Pitch' (82 S 1298)	Shiny black conchoidally fractured fragments with strong 'tarry' odour	Barrel in the hold
'Luting' (MR 82 S1274/12)	Small pieces of damp tarred wood with a strong 'tarry' odour	Main deck
Caulking (MR 82 S126)	Rope-like material composed of hair fibres impregnated with tar	Between the timbers forming the outer frame
'Tar' (82 S1296/7)	Thick black tarry material with 'tarry' odour	Barrel in the hold
Solid (81 S300)	Soft dark-brown solid, smelling strongly 'tarry'	Inside chest/box of longbows (probably intrusive)

Bracketed codes were used by the Mary Rose Trust to document the samples. For simplicity the term 'pitch' has been used in the text but the terms 'tar' and 'pitch' are not synonymous. Tar is the initial pyrolysate, which may then be thickened to pitch by boiling to drive off volatiles and effect a degree of further polymerization. Pitches of different softening points are obtainable in this way, but the present study does not attempt to distinguish between them or tars.

The remarkable similarities between the composition of the *Mary Rose* samples and 'Stockholm tar' clearly indicate that the sixteenth century and present-day tars and pitches are of the same generic type. These chemical data are in agreement with the historical and geographical evidence for the probable sources of the *Mary Rose* pitch[12].

Although the hydrocarbon distributions of the homogeneous pitch contained in the barrels are obviously similar to modern 'Stockholm tar', those obtained from the pitches already in their intended site of application (for example, 'luting', caulking and anchor rope) are somewhat different and variable[12]. Nevertheless, they do comprise only the characteristic diterpenoid hydrocarbons referred to above. The differences in distribution may reflect varying degrees of microbial alteration, weathering or water washing during the ship's 36-yr active life and subsequent 437-yr submergence and burial. Alternatively, they may reflect differing means of preparation before use.

It is notable that none of the abietic acid (compound 4) commonly observed in pine resins[10,11] was detected in either the *Mary Rose* samples or the 'Stockholm tar'. Presumably, the abietic acid present in the wood is thermally dehydrogenated and, to a lesser extent, decarboxylated during the retorting process, to produce the mixture of diterpenoid hydrocarbons, methyl dehydroabietate and dehydroabietic acid described above.

Today Stockholm tar or similar tars are imported into the United Kingdom from Russia, Eastern Europe, Scandinavia, China, America and India. At the time of the *Mary Rose*, it is known that trade developed between Russia and England, and amongst the first cargos were tar and pitch[13,14]. The similarity in chemical composition between the *Mary Rose* samples and the modern Russian Stockholm tar is consistent with the *Mary Rose* pitch having originated from one such cargo, but a local source of manufacture cannot be ruled out.

We have recently examined further pitch samples from an excavation in York (early medieval) and an Etruscan shipwreck (600 BC) discovered off the Island of Giglio, Italy. Both exhibited infrared spectra similar to those of Stockholm tar and *Mary Rose* pitch. CGC/MS analyses have also shown them to

contain abundant diterpenoid compounds. Clearly, pine wood derived tars and pitches have been in use as maritime waterproofing agents for well over 2,000 yr.

This investigation demonstrates the power of GC and GC/MS in the analysis of the organic components of archaeological materials and illustrates the scope of the problems awaiting the application of modern analytical methodology.

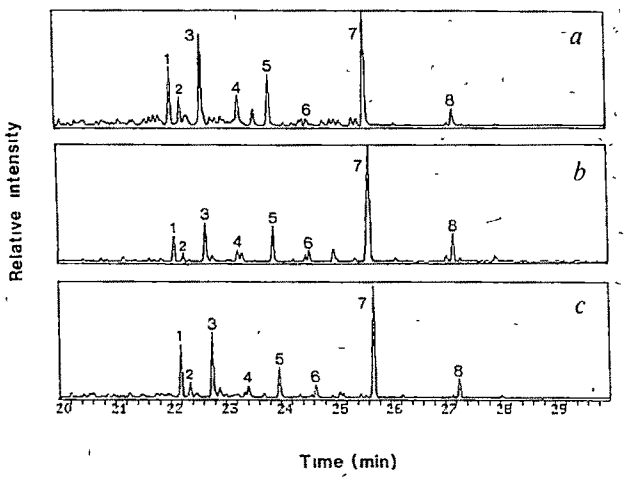


Fig. 1 Partial gas chromatograms showing the hydrocarbon fractions of: *a*, *Mary Rose* tar (82 S 1296/7); *b*, *Mary Rose* pitch (82 S 1298), *c*, present-day 'Stockholm tar' obtained by the destructive distillation of pine wood of the genus *Pinus*. Peak assignments of the alkyl-substituted tricyclic diterpenoid hydrocarbons were by CGC/MS using a Finnigan 9610 GC linked to a Finnigan 4000 quadrupole MS. Data acquisition and processing were performed using a Finnigan INCOS 2300 data system. Peak identities are: 1 = 19-norabieta-8,11,13-triene (M^+ 256, $C_{19}H_{28}$); 2 = unknown (M^+ 254, $C_{19}H_{26}$); 3 = 18-norabieta-8,11,13-triene (M^+ 256, $C_{19}H_{28}$); 4 = simonellite (?, M^+ 252, $C_{19}H_{24}$), 5 = 1,2,3,4-tetrahydroretene (M^+ 238, $C_{18}H_{22}$); 6 = mixture, predominantly ethylmethylphenanthrene (M^+ 220, $C_{17}H_{16}$); 7 = retene (compound 1) (M^+ 234, $C_{18}H_{18}$); 8 = unknown higher homologue of retene (M^+ 248, $C_{19}H_{20}$). Where the *Mary Rose* pitches were neither adhered to, nor incorporated into, any other materials, no extraction was necessary. In the cases of the caulking, 'luting' and rope samples, their associated pitch required extraction before analysis, achieved by placing the sample in an elution tube plugged with pre-washed cotton wool and washing with DCM (~200 ml). Extraction was continued until no further coloration appeared in the solvent washings. Removal of the DCM by rotary evaporation rendered the pitch extract free from particulate matter. Preliminary examination of the *Mary Rose* pitches and extracts was performed by infrared spectrophotometry as either melted films or as solutions in DCM. The infrared spectra of all the *Mary Rose* samples were similar, displaying absorptions assignable to carboxylic acid groups and aliphatic and aromatic moieties, and are very different from those recorded for petroleum bitumens and coal tars, but show some similarity to that obtained from a peat tar. The most striking similarities were observed between the *Mary Rose* samples and commercial 'Stockholm tar', whose spectrum is comparable in almost every respect (cm^{-1} and absorption intensity) to those of the *Mary Rose* pitches. Further comparisons required detailed molecular analysis by GC and GC/MS In preparation for this, aliquots (~1 g) of the various tars and pitches were fractionated by liquid chromatography (LC, alumina, Al_2O_3) using gradient elution (100 ml each of *n*-hexane, toluene, DCM, ethyl acetate and methanol). Isolation of the acidic components of a *Mary Rose* tar (82 S 1298) and 'Stockholm tar' was achieved by shaking aliquots (0.5 g) of tar dissolved in DCM (5 ml) with aqueous potassium hydroxide (KOH, 5%, 4 × 5 ml) Neutralization (5 M HCl) of the aqueous extract, and extraction (DCM, 3 × 20 ml) produced the acids, which were converted to their corresponding methyl ester derivatives using ethereal diazomethane. Analyses were performed on a Carlo Erba 4160 GC, using on-column injection. The column was 25 m × 0.3 mm i.d. OV-1 coated flexible silica capillary column (Chrompak). Hydrogen was the carrier at 100 cm s^{-1} and the GC oven temperature was programmed over 50–300 °C at 6 °C min^{-1}. The GC runs were acquired on a VG Analytical Minichrom data system[15].

We thank the Mary Rose Trust for provision of samples and especially Mr I. Oxley and Dr M. Rule for valuable discussions. We also thank Mr M. Bound and the World Ship Trust for pitch from the Giglio wreck (courtesy of the Superintendency of Archaeology for Tuscany) and York Archaeological Trust for supplying the early medieval caulking; Dr W. Ladner and colleagues of the Coal Research Establishment for reference samples of coal and peat tars; Mr M. I. Danischewsky of the White Sea and Baltic Tar Company, Mr D. W. Kelly of Carbotech and Dr S. C. Brassell for valuable discussions; Mrs A. P. Gowar and Mr C. L. Saunders for assistance with CGC/MS facilities, NERC for grants (GR3/2951 and GR3/3758) providing GC/MS and MS computing facilities, and British Petroleum p.l.c. for financial support (R.P.E.).

Filamentous microfossils from the 3,500-Myr-old Onverwacht Group, Barberton Mountain Land, South Africa

Maud M. Walsh & Donald R. Lowe

Department of Geology, Louisiana State University, Baton Rouge, Louisiana 70803, USA

The Swaziland Supergroup, Barberton Mountain Land, South Africa, has long been regarded as a promising location for the Earth's oldest fossils because it includes some of the most ancient well-preserved sedimentary rocks, many of which contain carbonaceous matter. Although there have been numerous reports of microfossils from Swaziland Group rocks[1–7], the biogenicity of most of the structures has been questioned[8–10]. Although some of the organic spheroids are probably biogenic[10,11], the best early Archaean simple spheroids are generally regarded as 'possible microfossils'[10] because organic spheroids may form abiotically in several ways[12]. The discovery of less-simple biological morphologies is therefore important in establishing the existence of early life forms in the early Archaean. Uniformly-sized curving filaments, especially tubular ones, are difficult to explain as anything other than the fossil remains of filamentous organisms. Here we report the discovery of numerous filaments from two different stratigraphical positions in the 3,500-Myr-old Onverwacht Group of the Swaziland Supergroup. Their morphologies and abundance provide convincing evidence for the existence of bacteria- or cyanobacteria-like organisms on the Earth during the early Archaean. This supports recent reports of similar filamentous microfossils from 3,500-Myr-old rocks from Western Australia[13].

The Onverwacht Group consists of ultramafic and mafic lavas interbedded with minor felsic tuffs and sedimentary units, including carbonaceous cherts. Nd–Sm dating of komatiitic flows in both lower and upper parts of the Onverwacht Group yields an age of 3,500 Myr[14]. A minimum age of 3,300 Myr for

the Onverwacht Group is provided by K–Ar dating of low-grade regional metamorphism which has affected the entire sequence[15].

The oldest unit in which we have identified filamentous microstructures is located near the top of the Hooggenoeg Formation in the upper half of the Onverwacht Group (Fig. 1). The structures occur in a black and white banded chert that is interbedded with thin silicified volcaniclastic layers at the base of a thick sequence of felsic tuffs and conglomerates. It crops out ~2 km north of the Komati Gorge section described by Viljoen and Viljoen[16]. The Hooggenoeg sample locality is 26°00′30″S, 31°00′05″E. It is exposed in a south-west-facing fault escarpment of the major ridge that generally trends north-east. A native trail crosses the ridge in a saddle south of the outcrop. Carbonaceous matter in the black chert bands occurs as fine laminae, as granules draped by laminae and as layers of irregularly shaped grains. The carbonaceous matter is identified by its petrographic characteristics—its brown-black colour and lack of crystallinity. Furthermore, whole rock analyses yield a total organic carbon content of 0.04%. Within this layer, the filamentous structures are thread-like or cylindrical and non-septate (Fig. 3*a*), with cross-sectional diameters ranging from <0.2 μm to 2.6 μm (Fig. 2*a*). The filaments are the same colour as surrounding organic matter, so they are probably partially carbonaceous. In addition, fine pyrite grains along the filaments are visible using reflected light microscopy. In a single carbonaceous layer ~2.5 cm thick, 185 individual filaments were noted in a total area of thin section 20-cm square.

The second sample containing carbonaceous filaments was collected in the immediately overlying Kromberg Formation. The filaments occur in a section of black and white banded cherts interlayered with flat- and cross-laminated clastic carbonates ~380 m above the base of the formation in the Komati Gorge section of Viljoen and Viljoen[16]. (The Kromberg sample locality is 26°01′42″S, 30°00′05″E. The prominent outcrop of banded chert is exposed on the path along the south bank of Komati River, ~2 km upriver from the footbridge.) The fossiliferous sample consists of alternating bands of brown-black carbonaceous chert and colourless translucent chert. The total organic carbon content of the rock is 0.11%. The carbonaceous chert layers, varying from 0.3 to 4 cm thick, have undulating tops and bottoms and are made up of billowy brown-black organic matter interlayered with fine carbonaceous laminae, both permineralized with silica. Within the fine laminae are mudstone clasts and pellets of organic matter. Many of the filaments are associated with the fine laminae, but some are within the cloudy organic matter. There are at least two distinct populations of filaments present. The most abundant filaments are threadlike (Fig. 3*b*, *f*), ranging in diameter from 0.1 to 0.6 μm and lengths from 10 to 150 μm (Fig. 2*b*). The other population consists of tubular filaments (Fig. 3*b*, *c* and *d*) with cross-sectional diameters ranging from 1.4 to 2.2 μm and lengths from 10 to 150 μm (Fig. 2*b*). Most filaments in this size range appear non-septate, but a few exhibit slight constrictions at intervals of ~1 μm. Based on the same transmitted and reflected microscopic criteria described for the Hooggenoeg sample, the filaments appear to be composed of carbonaceous matter, and in some cases admixed pyrite grains. The filaments are much more abundant in this sample than in the Hooggenoeg sample, with more than 200 individuals located in a 2.4-cm square area of thin section.

The age of the filaments, only slightly more than 1,000 Myr younger than the Earth itself, requires that the structures be appraised carefully with respect to their biogenicity. First, the characteristics of the rocks containing the filaments must be considered. All of the relevant features of the rocks are consistent with biogenicity of the filaments. The rock units in which the fossiliferous samples occur are clearly sedimentary units. The Hooggenoeg sample is in a 3.5-m-thick section of interbedded black and white cherts and flat- and cross-laminated sand and volcanic accretionary lapilli. The cherts are part of the sequence, with conformable contacts with over- and under-lying sand units. The sedimentary sequence overlies a komatiitic lava flow that has a brecciated weathered top. The Kromberg sample is from cherts that have a sedimentary lower contact with a pillowed lava flow. The flow has a brecciated top and signs of alteration due to submarine weathering. The section of cherts is conformably overlain by flat- and cross-laminated carbonates[17]. Traced laterally, the chert unit maintains its position in the sequence and is an original part of the sedimentary sequence. The rocks have undergone only low-grade metamorphism[16] and thus have not been heated sufficiently to destroy carbonaceous fossils. The black or brown-black colour of the organic matter in the rocks indicates that it has experienced heating conditions consistent with low-grade metamorphism[18]. The similar thermal history of the carbonaceous matter and the surrounding rocks strengthens the argument for a similar time of formation for the carbonaceous rocks and the surrounding sediments and volcanic flows. Carbon isotope analyses on black-and-white-banded cherts from the same Kromberg section yield $^{13}C_{PDB}$ values of −34.5 and −33.9 ± 0.2‰. These values are close to values reported for both Archaean and Proterozoic fossiliferous stromatolitic samples[18]. Perhaps most importantly, the microscopic texture of the carbonaceous cherts is like that of stromatolitic cherts, although larger-scale stromatolitic relief is lacking. The fine

crinkly apparently-coherent carbonaceous laminae are similar to those formed by microbial mats populated by filamentous organisms that precipitate and/or trap sediment between successive growth layers.

Characteristics of the filaments themselves indicate that they are both indigenous to the original deposit and biological in origin. The filaments are located far from any weathering surfaces or veins and have a similar colour to surrounding organic matter, indicating a similar thermal history. The filaments are, therefore, unlikely to be recent endolithic organisms[19]. The filaments cut across crystal domains and are thus not merely concentrations of organic matter at crystal boundaries. Both the size and the shape of the carbonaceous filaments are similar to those of modern filamentous bacteria and cyanobacteria and Proterozoic filamentous fossils interpreted to be the remains of cyanobacteria or bacteria[20–24]. The filaments are abundant and have a narrow size range. Each filament has a fairly constant diameter along its length. The spatial relationship of the filaments to lamination, generally either subparallel or perpendicular (Fig. 3), is like that of filaments in modern fossil mats constructed by phototrophic organisms[25]. Many of the thread-like filaments that are aligned parallel to bedding appear ribbon-like, as if they had been compressed during sediment compaction (Fig. 3*f*). Such flattening of microfossils has been described from both shales[26] and cherts[27]. Solid minerals or recent contaminants would be unlikely to show such flattening. The apparent composition of the filaments, carbonaceous matter and fine pyrite, is consistent with biogenicity. Filamentous microfossils consisting of pyrite grains have been reported from both the Beck Springs Dolomite[28] and the Gunflint Formation[21] and haematite-coated cylindrical microfossils are found in the Belt Supergroup[29]. Furthermore, cross-sectional views of larger filaments in the Kromberg sample show that they are hollow tubes, not solid mineral cylinders (R. J. Horodyski, personal communication. Horodyski has noted solid pyritic cylinders of abiogenic origin in cherts of the Belt Supergroup, Northwestern Montana.) The presence of pyrite along the filaments means either that the pyrite replaced the organic matter making up the walls of degrading filaments, or that the pyrite or a mineral it replaced was precipitated on the living organisms. Note that the apparent diameters of the filaments may reflect pyrite crystal size, or thickness of the pyrite coating, and not original filament size.

The filaments reported here represent the most probable biological microstructures yet reported from the Swaziland Supergroup and are similar in age to carbonaceous filamentous microfossils described from rocks in the eastern Pilbara block, Western Australia[13]. They are also the same age as the oldest known stromatolites, reported from Western Australia[30,31]. Carbonaceous cherts with organic mat-like textures are not uncommon in the Swaziland Supergroup. Their abundance, the above described microfossils and the occurrence of both microfossils and stromatolites in Western Australia provide compelling evidence for the existence of mat-forming organisms in early Archaean shallow water environments.

This research was supported by NSF grant EAR 78-19908 to D.R.L. and an NSF graduate fellowship to M.M.W. We thank R. J. Horodyski and A. H. Knoll for guidance and encouragement. Discussions with many participants in the 1982 NASA Planetary Biology and Microbial Ecology research conference were very useful. S. M. Awramik read an early version of the manuscript. G. R. Byerly provided the Hooggenoeg sample, as well as useful criticism. Total organic carbon analyses cited were performed at the University of Cape Town. Carbon isotope analyses were provided by J. M. Hayes of Indiana University. The samples described are housed in the Louisiana State University collection of Precambrian rocks and are available for examination through D.R.L.

Opposite motivational effects of endogenous opioids in brain and periphery

Antoine Bechara & Derek van der Kooy

Department of Anatomy, University of Toronto, Toronto, Ontario, Canada M5S 1A8

Many psychoactive drugs, including the opiates, have been shown to have paradoxical reinforcing effects[1,2]. Opiates produce positive reinforcing effects when they are paired with visual and textural environmental stimuli in rats[3,4], yet, at similar doses and over the same routes of administration, produce aversive effects, as shown when they are paired with taste stimuli[5]. Similarly, in human, the positive reinforcing effects of opiates are well known to addicts and recreational drug users, yet patients receiving opiates as analgesics often report nauseous reactions. At present there is no evidence to differentiate between the neural substrates that mediate these opposite motivational effects. We now report an initial step in the resolution of this paradox by demonstrating that endogenous and exogenous opioids produce positive reinforcing effects through an action on brain opiate receptors, and aversive effects through an action on peripheral opiate receptors (especially in the gut).

The microinjection of morphine directly into certain specific brain sites can produce positive reinforcing effects similar to those seen after systemically administered drug[1]. The central dose required to produce these effects is lower than that needed to produce similar effects after systemic administration, suggesting that the primary population of receptors mediating the positive reinforcing effects is localized in the brain[6]. Recently, a large population of opiate receptors has been found on primary sensory neurones in the peripheral nervous system[7]. Local application of opiates in the periphery produces receptor-mediated hyperalgesic or irritation effects[8]. These results suggest that opiates, and by analogy endogenous opioids, produce positive reinforcing effects in the brain and aversive effects in the periphery. To test this hypothesis, we studied the motivational effects of specific opioid receptor antagonists which do or do not cross the blood–brain barrier.

Using a place-preference paradigm[3], separate groups of drug-naïve rats were administered (subcutaneously (s.c.) or intraperitoneally (i.p.)) various doses of naltrexone or its quaternary derivative methylnaltrexone, which does not cross the blood–brain barrier effectively[9]. Briefly, each rat received four drug injections spaced equally over 8 days, and was immediately confined after each injection to a visually and texturally distinctive environment for 30 min. On the 4 alternating days when no opiate antagonist injection was given, each rat was injected with

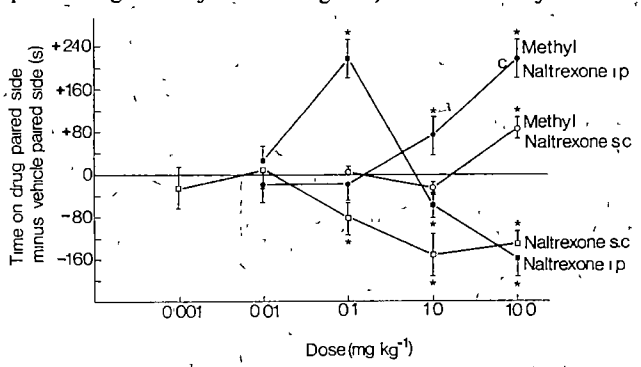

Fig. 1 Effects of various doses of naltrexone and methylnaltrexone (s.c. and i.p.) in the place-conditioning paradigm. Each point represents the mean ± s.e.m. for eight rats ($*P < 0.05$). Overall analyses of variance on the data from i.p. (0.01–10 mg kg^{-1}) and s.c. (0.1–100 mg kg^{-1}) injections revealed most importantly significant three-way interactions of time in the drug-versus-saline paired environment with drug and with dose ($F_{3,42} = 19.57$ (i.p.), $F_{2,28} = 12.91$ (s.c.), $P < 0.005$).

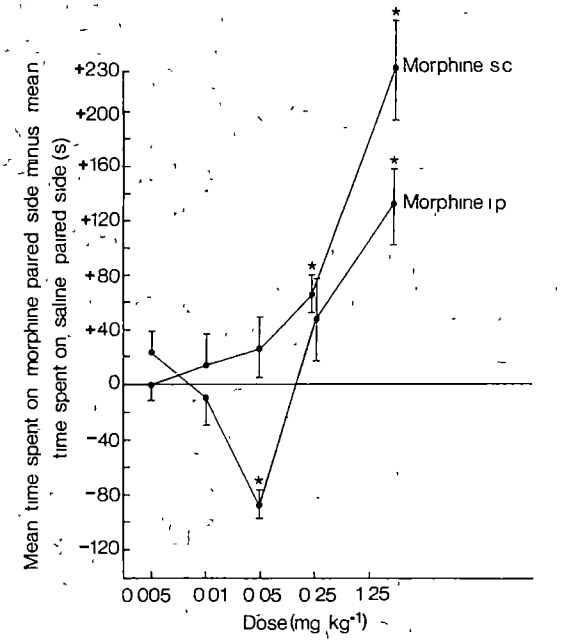

Fig. 2 Effects of various doses of morphine (s.c. and i.p.) in the place-conditioning paradigm. Each point represents the mean ± s.e.m. for eight rats ($*P < 0.05$).

saline vehicle and confined for 30 min to another separate and different distinctive environment[3]. Order of injections and drug-paired environment were counterbalanced within groups. On day 9, each uninjected rat was tested by recording the amount of time the rat spent in each of the two previously paired distinctive environments when given a 10-min period to explore both environments freely.

Figure 1 shows that, regardless of the route of administration, increasing doses of naltrexone were aversive whereas increasing doses of methylnaltrexone were positively reinforcing. The results suggest that the place aversions observed were due to an antagonism by the antagonist of endogenous opioid peptides acting on central opiate receptors. This suggestion is based on the fact that most opiate receptors are located in the brain and therefore the net effects of naltrexone, which can cross the blood–brain barrier, are mainly caused by its binding to central receptors. Similar results have been reported previously using another opiate antagonist, naloxone[3]. The preferences produced by methylnaltrexone, which does not effectively cross the blood–brain barrier, must result primarily from its binding to peripheral opiate receptors and its blockade of peripheral endogenous opioid actions.

Interestingly, one anomalous result occurred at 0.1 mg kg^{-1} naltrexone i.p., but not s.c., which produced a place preference ($F_{1,7} = 17.23$, $P < 0.05$). We hypothesized that this was the result of a local block of aversive opiate effects in the gut without significant central action at this low dose. This implies that the peripheral aversive effects of opiates are mediated primarily by receptors in the gut. Based on this hypothesis, we predicted that a low dose of morphine, given i.p., should produce aversion. Figure 2 shows that 0.05 mg kg^{-1} of morphine (i.p.) produced significant place aversions ($F_{1,7} = 27.47$, $P < 0.05$); the same dose administered s.c. had no effect. Higher doses of morphine (s.c. and i.p.) were positively reinforcing in the place-preference paradigm; doses below 0.05 mg kg^{-1} had no effects. Because the vagus nerve carries sensory information from the gut to the brain, we predicted further that subdiaphragmatic vagotomies should abolish the observed effects at the low doses of i.p. morphine and naltrexone (0.05 mg kg^{-1} morphine place aversions and 0.1 mg kg^{-1} naltrexone place preferences), but should not abolish the opposite motivational effects seen at higher i.p. doses (1.25 mg kg^{-1} morphine place preferences and 10.0 mg kg^{-1} naltrexone place aversions). Figure 3 confirms these predictions. Vagotomy (verified at death by measuring

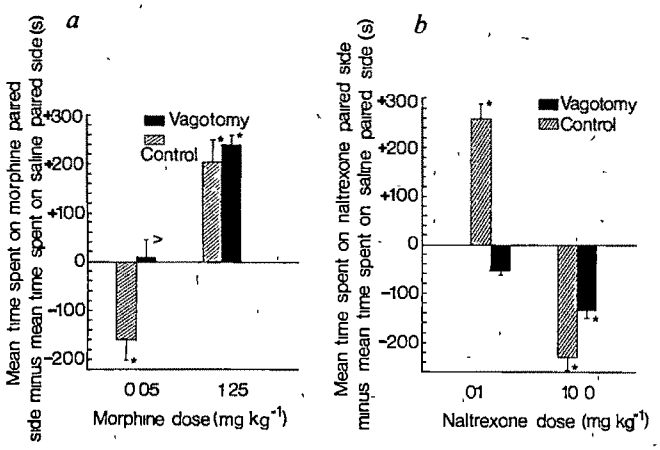

Fig. 3 *a*, Effects of vagotomy on the low-dose i.p. morphine place aversions and higher-dose i.p. place preferences. *b*, Effects of vagotomy on the low-dose i.p. naltrexone place preferences and higher-dose i.p. place aversions. Bars are means ± s.e.m. for 7–12 rats. * Indicates significant place conditioning ($P < 0.05$). Overall analyses of variance on the data from control and vagotomized animals injected with morphine and naltrexone revealed significant two-way interactions of control versus vagotomized animals with time in drug-versus-saline paired environment ($F_{1,14} = 17.88$, $P < 0.05$ (naltrexone); $F_{1,22} = 6.05$, $P < 0.05$ (morphine)).

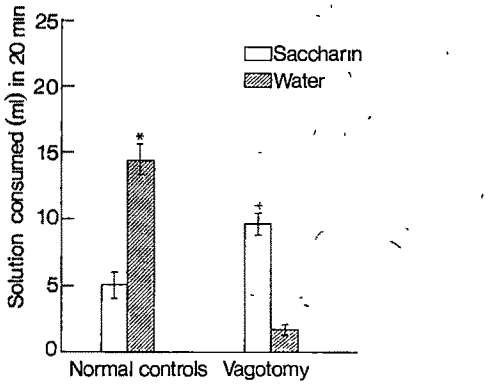

Fig. 4 Effects of vagotomy on the aversions elicited by high-dose i.p. morphine injections in the conditioned taste aversion paradigm. Bars are means ± s.e.m. for 7–10 rats. * Indicates a significant difference between saccharin and water consumption ($P < 0.05$).

food retention in the stomach[10]) blocked the 0.05 mg kg^{-1} morphine-induced place aversions and the 0.1 mg kg^{-1} naltrexone-induced place preferences. No significant effects of vagotomies were observed on the 1.25 mg kg^{-1} morphine place preferences nor on the 10.0 mg kg^{-1} naltrexone place aversions. These data support the hypothesis that the aversive properties of opiates are mediated by means of gut opiate receptors.

We tested this hypothesis further by investigating the effects of vagotomy on the aversive effects of opiates in the conditioned taste aversion paradigm[5], where only aversive effects are seen even with higher doses of morphine. Fluid-deprived vagotomized ($n = 7$) and control ($n = 10$) rats received five 20-min presentations (spaced equally over 10 days) of 0.1% saccharin solution followed immediately by a morphine injection (15 mg kg^{-1}, i.p.), and on the 5 alternating days normal water paired with saline vehicle injection. Overall analyses of variance on a final drug-free, 20-min, two-bottle choice test revealed a significant two-way interaction of vagotomy versus control with saccharin versus water consumption ($F_{1,18} = 18.35$, $P < 0.05$). The control rats demonstrated an aversion for the saccharin flavour previously paired with morphine, whereas the vagotomized and morphine-injected rats showed the normal preference for saccharin (Fig. 4) seen in uninjected animals. These results again suggest that the vagus nerve carries information concerning the aversive properties of opioids from the gut to the brain.

In conclusion, endogenous and exogenous opioids acting on peripheral receptors (especially in the gut) produce aversive or nauseous effects, whereas opioids acting on central brain receptors produce positive reinforcing or euphoric effects. The present results suggest that the adverse effects of opiates experienced in human patients receiving opiates for analgesia might be minimized by blocking peripheral opiate receptors. These data also provide the first steps in analysing how the organization of the nervous system places constraints on the learning of associations between the two different, anatomically specific motivational effects of opioids and stimuli in different sensory systems.

This work was supported by the MRC of Canada. We thank Dr H. Merz for the gift of methylnaltrexone and Dr H. Weingarten for advice about vagotomies.

Role of guanine nucleotide binding protein in the activation of polyphosphoinositide phosphodiesterase

Shamshad Cockcroft & Bastien D. Gomperts

Department of Experimental Pathology, University College London, London WC1E 6JJ, UK

Interaction of ligands with 'Ca^{2+}-mobilizing' receptors is thought to result in the generation of two second messengers, inositol trisphosphate and diacylglycerol, from a common substrate, phosphatidylinositol 4, 5-bisphosphate (PtdIns(4, 5)P_2) (refs 1, 2), a component of plasma membranes[3,4]. It is not known how the occupation of such receptors is translated into the activation of the catalytic unit polyphosphoinositide (PPI) phosphodiesterase, and then to cellular activation, but our recent experiments suggest that GTP regulatory proteins may be involved. In mast cells, non-hydrolysable analogues of GTP introduced and then trapped in the cytosol are able to substitute for external ligands in inducing exocytosis, a well-defined Ca^{2+}-dependent process[5], suggesting that guanine nucleotide regulatory proteins may act by stimulating the catalytic activity of the PPI phosphodiesterase. We now provide evidence that mast cell secretion is inhibited by internalized neomycin, a compound known to interact with PPI[6]. We also show that the PPI phosphodiesterase of human neutrophil plasma membranes can be activated simply by adding GTP analogues in the presence of concentrations of Ca^{2+} that pertain in unstimulated cells. These findings strongly support the idea that the coupling factor linking receptor and PPI phosphodiesterase is a guanine nucleotide binding protein analogous to those involved in the activation and inhibition of adenylate cyclase[7].

Mast cells, when transiently permeabilized in the presence of the GTP analogue GTP-γ-S, secrete histamine when Ca^{2+} is added subsequently to the external medium[5]. To test the possibility that PPI hydrolysis is required for the action of GTP-γ-S, we investigated the effects of neomycin, which prevents the hydrolysis of PPIs. Figure 1 shows that when neomycin at 10–100 μM is loaded into the cytosol with GTP-γ-S (50 μM), Ca^{2+}-dependent secretion is abolished. Neomycin inhibits

Control	7,245±155	14,450±1,845
GTP-γ-S	11,746±344	21,072±370
Increase in label	4,501	6,672

Abbreviations: PtdIns(4)P, phosphatidylinositol 4-phosphate; PtdIns(4,5)P_2, phosphatidylinositol 4,5-bisphosphate, $InsP_2$, inositol bisphosphate; $InsP_3$, inositol trisphosphate. Human peripheral neutrophils were prepared as described previously[14]. The cells (10^8 per ml) were preincubated in a balanced salt solution[14] containing ^{32}P-phosphate (100 μCi ml^{-1}) for 90 min to prelabel the phospholipids, including the polyphosphoinositides. A light membrane fraction enriched in plasma membranes was prepared as described previously[25]. The plasma membrane suspension was suspended in 20 mM PIPES buffer containing 150 mM KCl, *p*H 6.8, at a protein concentration of 3–4 mg ml^{-1}. Samples (500 μl) were transferred to tubes containing GTP-γ-S and Ca-EGTA buffer (3 mM EGTA final) in an equal volume to give final concentrations of GTP-γ-S and Ca^{2+} of 100 μM and 100 nM, respectively. After 10 min at 37 °C, the reaction was terminated by the addition of 3.75 vol chloroform/methanol/concentrated HCl (100:200:5). This mixture was allowed to stand for 30 min and then separated into two phases by the addition of 1.25 vol each of chloroform and water. The lower (chloroform) phase was retained for lipid analysis and the upper (aqueous) phase retained for the determination of inositol phosphates Phospholipids were separated by TLC on oxalate-impregnated silica gel-H-coated plates using chloroform/methanol/acetone/acetic acid/water (40:13:15:12:8) and the radioactive spots located by autoradiography. Areas containing PtdIns4P and PtdIns(4,5)P_2 were scraped and the lipids hydrolysed in 72% perchloric acid at 180 °C for 1 h. The sample was made up to 10 ml in water and counted by Cerenkov radiation. For the analysis of the water-soluble inositol phosphates, the upper (aqueous) phase was neutralized, made up to 10 ml with water and run on Dowex 1 (formate form) as described previously[26]. Results (c p.m.) are expressed as the means (±s.d.) of triplicate determinations from a single experiment. Similar results were obtained in two other experiments. Samples of labelled membranes were also treated with Ca^{2+} (1 mM) alongside each experiment for comparison and on this particular occasion, Ca^{2+}-dependent activation of the phosphodiesterase caused loss of PtdIns4P (55%) and PtdIns(4,5)P_2 (65%) compared with GTP-γ-S-activated loss of PtdIns4P (20%) and PtdIns(4,5)P_2 (34%)

secretion only when presented to the cells together with ATP^{4-}, which causes cell permeabilization[8] and so permits the drug entry to the cytosol. This result suggested that PPI hydrolysis is an integral step in the activation of cells loaded with non-hydrolysable GTP analogues and that PPI phosphodiesterase is subject to control by a guanine nucleotide binding protein. To test this possibility, we used the PPI phosphodiesterase of human neutrophils. We have described recently a plasma membrane PPI phosphodiesterase in human and rabbit neutrophil membranes which can be activated in the presence of Ca^{2+} (ref. 9). Like the red cell enzyme[10], the neutrophil enzyme is not under the control of cytosol Ca^{2+} because Ca^{2+} is required in the millimolar range. The possibility must therefore be considered that the enzyme is controlled by some other so far unidentified component.

GTP-γ-S can activate the neutrophil enzyme (Table 1) in the conditions of Ca^{2+} homeostasis pertaining in resting cells. The hydrolysis of PPI yields the water-soluble products inositol bis- and trisphosphate. The loss of label from PPI is fully accounted for by the appearance of label in the inositol phosphates (Table 1). Data for Ca^{2+} activation of the enzyme are also included for comparison (see Table 1 legend). Our earlier experiments included Mg^{2+} (1 mM) in the incubation mixtures, but it soon became clear that this leads to hydrolysis of the inositol phosphates, with the implication that Mg^{2+}-requiring phosphatases

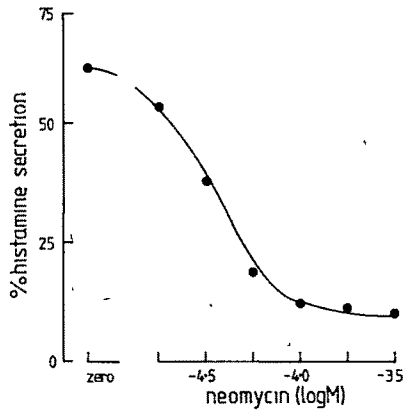

Fig. 1 Inhibition by neomycin of Ca^{2+}-dependent histamine secretion from GTP-γ-S-loaded mast cells. Exogenous solutes were loaded into the cytosol of rat mast cells as described previously[5]; they were treated with ATP (3.16 μM), GTP-γ-S (50 μM) and neomycin (concentrations as indicated on the abscissa). This treatment with ATP in the absence of divalent cations causes the formation of lesions in the plasma membrane and allows the other solutes present to penetrate into the cytosol. At 6 min, $MgCl_2$ (5 mM) was added to close the membrane lesions and so trap the loaded GTP-γ-S and neomycin in the cytosol. After 15 min further incubation, exocytotic secretion was triggered by the addition of Ca^{2+} (5 mM). The cells were quenched with ice-cold phosphate-buffered saline 10 min later, and secreted histamine was measured as described previously[8]. Neomycin at concentrations up to 300 μM had no effect on the histamine assay. The results illustrated are representative of four independent experiments

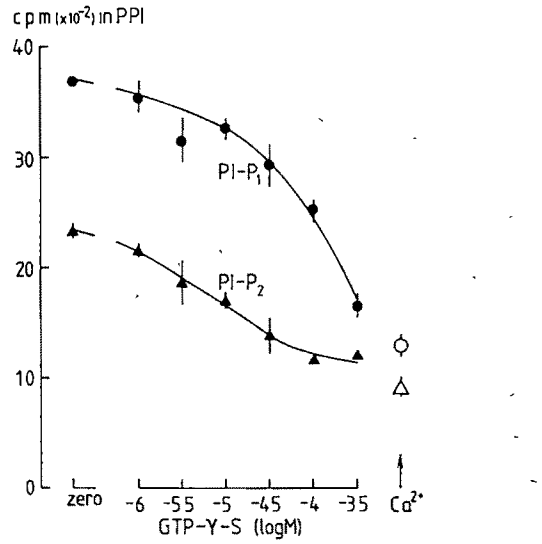

Fig. 2 Concentration–effect relationship of GTP-γ-S-activated polyphosphoinositide phosphodiesterase in neutrophil membranes Experimental details are the same as outlined in Table 1 legend except that the incubations were performed using 100 μl of membrane suspension added to 100 μl of buffer containing Ca-EGTA (100 nM Ca^{2+}), 1 mM Mg^{2+} (final) and GTP-γ-S as indicated For comparison, data for PPI phosphodiesterase activation by 1 mM Ca^{2+} are also shown (open symbols). The results illustrated are representative of four separate experiments. Results are expressed as c.p.m. in the individual polyphosphoinositides, determinations were made in triplicate. Error bars denote s.d. Circles denote PtdIns4P (PI-P_1) and triangles denote PtdIns(4,5)P_2 (PI-P_2).

are present; such phosphatases have been identified recently in the red cell[11]. Mg^{2+} was therefore excluded subsequently from experiments in which water-soluble derivatives were to be analysed. There was no indication that Mg^{2+} is required for the action of GTP-γ-S on the enzyme, and it has little effect on the inositol lipid phosphomonoesterase[9] and no effect on PPI phosphodiesterase[9].

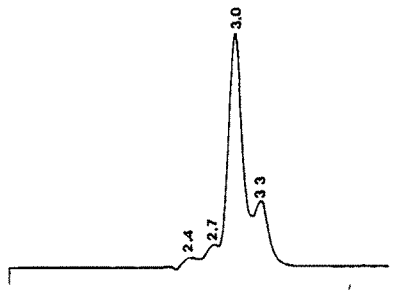

Fig. 3 HPLC analysis of commercial GTP-γ-S. GTP-γ-S (10 μl of 1 mM) was injected into a Bondepak cartridge-type column and the sample run isocratically as described previously[3,14]. Chart recording speed was set at 20 mm min^{-1}. GTP-γ-S and IDP were obtained from Boehringer Mannheim and all other nucleotides from Sigma. GppNHp was obtained from both sources and produced similar HPLC profiles. Elution times (min) for the various nucleotides were: ATP, 4.95; GTP, 2.98; GDP, 3 27; GMP, 4.47; ADP, 5 7; GTP-γ-S, 3.0 (68%) and 3.3 (20%, probably GDP); GppNHp, 3.07 (65%) and 3.42 (30%); $GppCH_2p$, 3.04; IDP, 3.32.

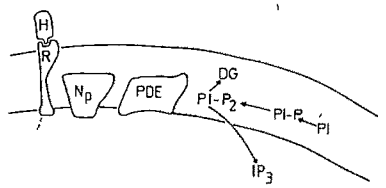

Fig. 4 Schematic description of events that occur when hormone binds to its receptor and results in transmembrane signalling. Interaction of hormone (H) with receptor (R) allows a guanine nucleotide binding protein (N_p) to exchange bound GDP for GTP. This generates an activated species of N_p which activates the catalytic unit, polyphosphoinositide phosphodiesterase (PDE). The hydrolysis of phosphatidylinositol bisphosphate (PI-P_2) generates two second messengers—diacylglycerol (DG) to activate protein kinase C and inositol trisphosphate to release Ca^{2+}—which then together mediate cellular responses. The supply of the substrate (PI-P_2) is limited by the activity of the inositol lipid kinases which sequentially phosphorylate phosphatidylinositol (PI) to phosphatidylinositol 4-phosphate (PI-P) and then to PI-P_2.

Activation of PPI phosphodiesterase was dependent on the concentration of GTP-γ-S in the range 1–300 μM (the highest concentration tested) (Fig. 2). Activity was already apparent at 1 μM and at higher concentrations approached activities that can be achieved by millimolar concentrations of Ca^{2+} (ref. 9). However, we stress that these results refer to the added compound, obtained from commercial sources. The guanine nucleotides are inherently unstable; in particular, there is a tendency towards deamination to yield inosine homologues[12]. Analysis by HPLC reveals that GTP-γ-S (Fig. 3) and GppNHp (see Fig. 3 legend) are always very impure; the impurity detected is most probably GDP in the case of GTP-γ-S (Fig. 3) and remains unidentified in the case of GppNHp. The proportions of the individual components did not alter during 8 months' storage. However, the HPLC method[13,14] does not resolve guanine from their equivalent inosine nucleotides, and so we cannot be certain of the actual concentrations required for activation of the enzyme, although we do know that the onset of activation occurs at concentrations <1 μM. In five separate experiments, 1 μM GTP-γ-S hydrolysed 10% (±2) (s.e.m., $n = 5$) of phosphatidylinositol 4-phosphate and PtdIns(4, 5)P_2.

We also tested the specificity of the GTP analogues, but the uncertainties involved in the actual concentrations present prevented us from quantifying their relative potencies. All compounds were tested at a nominal 100 μM. GDP, GDP-β-S, ATP, ATP-γ-S and AppNHp were inactive, whereas GTP-γ-S, GppNHp and $GppCH_2p$ caused activation. The effect of GTP was erratic, probably because of hydrolysis by a nonspecific nucleotidase known to be present in neutrophil plasma membranes[15].

The results described here provide firm evidence that PPI phosphodiesterase can be activated by analogues of GTP, and so by inference may be subject to control by the binding of GTP at a receptor-controlled guanine nucleotide binding protein (N-protein) in its cellular environment (Fig. 4). In this it is similar to adenylate cyclase, although there are also important differences. In particular, whereas the availability of substrate to adenylate cyclase is effectively inexhaustible, the substrate for PPI phosphodiesterase is an endogenous membrane lipid, strictly limited by the inositol lipid kinases, and thus perhaps under independent control (S.C., J. Lamb and E. Zanders, in preparation). Further, there are two products of phosphodiesterase action, one of which (diacylglycerol) is retained in the organic phase of the membrane, while the other (inositol trisphosphate) is released into the cytosol.

Binding of ligand to receptor leads to the binding of GTP and activation of N-protein. Different receptors are likely to interact with separate but related families of N-proteins; N_i, N_s and transducin have already been described[16]. We designate the putative N-protein which is involved in the activation of PPI phosphodiesterase as N_p; an inhibitory counterpart to N_p analogous to N_i probably also exists. The activated N_p is then responsible for switching on the PPI phosphodiesterase as shown in Fig. 4.

These ideas are further supported by the recent finding that islet activating protein (purified from pertussis toxin) can inhibit mast cell and neutrophil secretion induced by both internalized GTP analogues[17] and receptor-directed agonists[18]. This suggests that N_p is susceptible to ADP-ribosylation and thus inhibition similar to N_i and transducin.

The precedent for involving N-proteins was set initially by the adenylate cyclase system[7] and this role has now been extended not only to hormone receptor action, but also to the biosynthesis of proteins[19]. Other examples include the light-induced activation of cyclic GMP phosphodiesterase[20] and the activation of protein kinase and cyclic AMP phosphodiesterase by insulin[21,22]. The protein products of the *ras* oncogene family also have a binding site for GTP, again implying a role for N-protein[23,24]. Thus, the activation of PPI phosphodiesterase shares with other receptor and non-receptor signal-transducing systems a common mechanism of control involving a family of related but specific N-proteins.

Antigen-specific interaction between T and B cells

Antonio Lanzavecchia

Basel Institute for Immunology, Grenzacherstrasse 487, Postfach CH-4005, Basel, Switzerland

It is well known that B cells require T-cell help to produce specific antibody. Classic experiments suggested that antigen-specific helper T cells interact with antigen-specific B cells via an antigen 'bridge'[1,2], the B cells binding to one determinant on an antigen molecule (the 'hapten'), while the T cells at the same time recognize another determinant (the 'carrier'). T-helper cells bind specifically to antigen-presenting cells (APC), which have picked up and processed the appropriate antigen, and this interaction, like the interaction of T-helper cells with specific B cells, is restricted by products encoded by the major histocompatibility complex (*MHC*)[3-5]. Whereas conventional APC such as macrophages display no binding specificity for antigen, B cells have clonally distributed antigen-specific surface immunoglobulin receptors which would be expected to enhance their capacity to present antigen to T cells [6,7]. These findings are difficult to reconcile with the simple 'antigen bridge' mechanism of interaction, because it is hard to visualize how the bimolecular complex (processed antigen plus MHC molecule) on the APC surface can resemble the trimolecular complex (antigen bound to surface immunoglobulin plus MHC molecule) on the B-cell surface. To address this problem, we have cloned and immortalized human antigen-specific B cells with Epstein–Barr virus (EBV) and analysed their interaction with T-cell clones specific for the same antigen. We report here that surface immunoglobulin is indeed involved in the uptake and concentration of antigen, allowing specific B cells to present antigen to T cells with very high efficiency. However, the antigen must first be internalized and processed by specific B cells and it is then presented to T cells in an MHC-restricted manner indistinguishable from that characteristic of conventional APC.

Three B-cell clones producing IgG antibody against tetanus toxoid (TT) were isolated by EBV-induced transformation of peripheral blood B cells from an immune donor. The capacity of these B cells to bind antigen was tested by saturation analysis using ^{125}I-labelled TT. The double reciprocal plot of the bound versus free antigen showed an affinity constant of 5×10^7–2×10^8 l mol^{-1}, the number of binding sites varying from 2×10^4 to 10^5 per cell (see Table 1). The affinity for antigen of the secreted antibody was comparable within a factor of 3 to that of the B cells (data not shown). By contrast, B cells cloned from the same donor but producing IgG of an irrelevant specificity bound only very limited amounts of TT and showed no tendency for saturation. Furthermore, binding of ^{125}I-TT to TT-specific B cells was inhibited by unlabelled TT whereas binding to non-specific B cells was not (Table 1). These data indicate that specific B cells bind soluble antigen with a high affinity equal to the affinity of the antibody they produce, while B cells not specific for TT (nonspecific) bind much lower, although still measurable, amounts of antigen in an immunoglobulin-nonspecific way.

We compared the ability of TT-specific and nonspecific B cells to present TT or an unrelated antigen to T cells. The dose of antigen in culture was titrated for any T/B-cell combination and the T-cell proliferative response was assessed by thymidine incorporation. We found that both specific and nonspecific B cells were able to present native TT to TT-specific T-cell clones (Fig. 1*a*–*c*). However, while presentation by nonspecific B cells required high concentrations of antigen in culture (Fig. 1*c*), TT-specific B cells could trigger T-cell proliferation in the presence of 10^4-fold lower antigen concentrations (10^{-11}–10^{-12} M, Fig. 1*a*,*b*). We have obtained similar results in 12 T/B-cell combinations using 4 different T-cell clones and 3 different specific B-cell clones.

Table 1 Antigen binding by antigen-specific B cells

B-cell clone	^{125}I-TT bound per 10^6 cells (c.p.m.)	k (l mol^{-1})	No. of sites per cell
11.3	43,529 (1,039)	5×10^7	10^5
8.5	26,834 (593)	2×10^8	2×10^4
4.2	21,067 (912)	5×10^7	5×10^4
7.1	841 (730)	ND	ND

TT was labelled with ^{125}I by the chloramine-T method. B cells from three TT-specific EBV-transformed B-cell clones (11.3, 8.5 and 4.2) or from a clone producing an immunoglobulin of irrelevant specificity (7.1) were incubated with increasing concentrations of ^{125}I-TT in 200 µl phosphate-buffered saline containing 0.5% bovine serum albumin and 15 mM NaN_3. After 1 h on ice, the cells were pelleted and 100 µl of supernatant was collected. The cells were resuspended, washed twice by centrifugation through a cushion of fetal calf serum (FCS) and the radioactivity bound was determined. c.p.m. represent the amount of ^{125}I-TT bound near the saturation point of the curve. Numbers in parentheses indicate c.p.m. bound at the same concentration of labelled TT in the presence of a 100-fold excess of cold TT. k, The affinity of TT binding by B cells, and the number of binding sites were calculated from the double reciprocal plot of the saturation curve as described previously[12]. ND, the value was not determined because saturation could not be achieved.

TT	—	12,373	79,175	21,708
Chloroquine+TT	—	220	962	21,582

Expt 1: A TT-specific B-cell clone (8.5) was washed, resuspended in RPMI/FCS and incubated on ice with native TT (5×10^{-10}M) or with a rabbit anti-human F(ab')$_2$ affinity-purified antibody (300 µg ml^{-1}). After 15 min, anti-F(ab')$_2$ or anti-TT were added as indicated for 1 h. The cells were then washed three times, irradiated (3,000 R) and cultured with TT-specific T cells as described in Fig 1 legend. Native TT (5×10^{-10} M) or anti-immunoglobulin (300 µg ml^{-1}) were added where indicated. Expt 2: A TT-specific B-cell clone (11.3) was washed, resuspended in RPMI 10% FCS and pulsed at 37 °C with 10^{-9} M native TT or medium alone in the presence or absence of 10^{-5} M chloroquine. After 4 h the cells were washed four times with Hank's balanced salt solution (HBSS) and fixed with 0.05% glutaraldehyde for 1 min at room temperature. The reaction was stopped with 0.2 M glycine in HBSS and the cells were washed three times. Glutaraldehyde-fixed and fresh B cells bound, respectively, 44,331 and 31,520 c.p.m. of ^{125}I-TT per 10^6 cells. Fixed cells (5×10^4) were cultured in 96-well U-bottom microplates with 2×10^4 T cells from TT-specific clones (KT2 and KT4) or an alloreactive clone (AK3) specific for K.K. (the TT-immune donor) as a control. Soluble TT was added in culture at 10^{-7} M where indicated. Thymidine incorporation was measured as in Fig. 1. Data represent the geometric mean of triplicate determinations

As a specificity control, we compared the ability of TT-specific and nonspecific B cells to present two antigens not recognized by their specific surface antibodies. The first was the denatured form of TT itself. As generally found for complex protein antigens[8], denaturation of TT followed by reduction and carboxymethylation results in an antigen preparation that has lost the

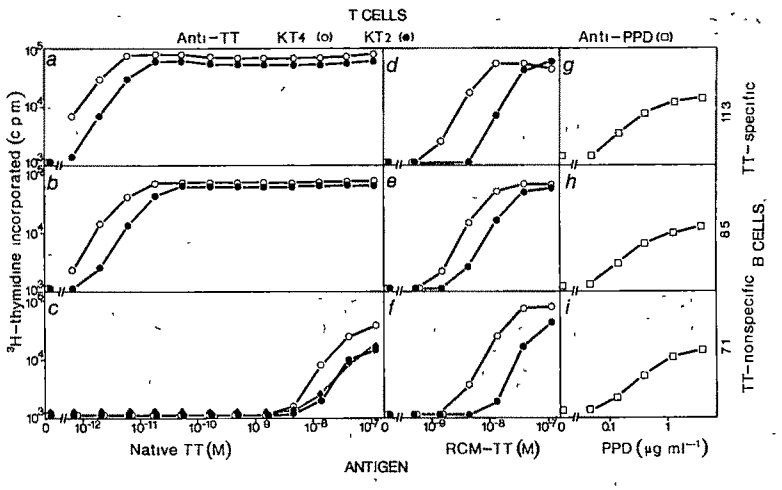

Fig. 1 Antigen presentation by antigen-specific B lymphocytes. Cells (2×10^4) from the TT-specific T-cell clones KT2 (●) and KT4 (○) or from a PPD-specific T-cell line (□) were cultured with 2×10^4 irradiated (3,000 R), EBV-transformed B-cell clones specific for TT (*a, d, g,* clone 11.3; *b, e, h,* clone 8.5) or non-TT-specific (*c, f, i,* clone 7.1) in 200 μl RPMI/FCS in 96-well flat-bottom microplates. The cultures were stimulated with a wide range of concentrations of native TT, reduced carboxymethylated-TT (RCM-TT) or PPD. In *c*, clone KT2 was also stimulated in the presence (◆) of 3 μg ml^{-1} purified antibody produced by clone 11.3. After 2 days the cultures were pulsed for 16 h with 1 μCi ^{3}H-thymidine and the incorporated radioactivity was counted. The background of irradiated B cells alone (always <3,000 c.p.m.) was subtracted.

Methods. Antigens: Native TT was obtained from the Massachusetts Public Health Biological Laboratories and purified by gel filtration on Sephadex G-200. RCM-TT was prepared by denaturation of native TT in 6 M urea, followed by reduction with dithiothreitol and carboxymethylation with iodoacetic acid. The anti-TT antibody produced by specific B cells (see below) was purified from the culture supernatant and coupled to CNBr-activated Sepharose. This immunoadsorbent was used to deplete RCM-TT of contaminating antigen still reactive with these antibodies. This antigen preparation contained <0.1% antigen still reactive with antibody as detected by inhibition of binding of ^{125}I-TT. PPD was obtained from Serum Institut, Copenhagen. T cells: T-cell clones specific for TT were derived as described previously[11]. Briefly, peripheral blood mononuclear cells (PBM) from a TT-immune donor (K.K.) were stimulated *in vitro* with 10^{-7} M TT. After 7 days, the activated T cells were expanded in medium supplemented with 30 U ml^{-1} recombinant interleukin-2 (IL-2, Biogen) and 2 weeks later restimulated with TT and autologous irradiated (3,000 R) PBM. After a further expansion in IL-2, the cells were cloned by limiting dilution in the presence of irradiated autologous PBM, TT and IL-2. Five TT-specific clones were isolated and maintained in culture for more than 8 months by periodic restimulations with antigen, followed by expansion in IL-2. All the T cells used in the present experiments were obtained from 3–4-week-old IL-2-dependent cultures and were virtually devoid of contaminating APC, as they were unable to proliferate in response to soluble antigen unless appropriate APC were added. PPD-specific T cells from donor K.K. were also obtained from PBM stimulated with PPD. The cells were selected by three cycles of restimulation and grown in IL-2 as described above. B cells: TT-specific B-cell clones were obtained from donor K.K. by EBV transformation of peripheral blood B cells essentially as described elsewhere[13]. PBM (10^7) were resuspended in 10 ml RPMI/FCS containing 30% supernatant of the EBV-producing marmoset cell line B95.8 and 600 ng ml^{-1} cyclosporin A (Sandoz). After 16 h at 37 °C, the cells were washed and seeded at 5×10^4 cells per well in 96-well flat-bottom microplates in 200 μl RPMI/FCS containing 600 ng ml^{-1} cyclosporin A. After 13 days the supernatants were tested for the presence of IgG anti-TT antibodies by enzyme-linked immunosorbent assay[11]. Cells from eight positive wells were cloned and subcloned by limiting dilution in the presence of 3×10^5 rat thymocytes as filler cells. Three different TT-specific clones producing IgG anti-TT antibody (0.5–5 μg ml^{-1}) were isolated as well as several other clones producing IgG not specific for TT.

ability to react with antibodies while maintaining the capacity to stimulate T cells. Figure 1*d–f* shows that there is no significant difference in the low efficiency with which TT-specific and nonspecific B cells present the denatured form of TT. As a further control, an unrelated antigen, purified protein derivative of tuberculin (PPD), was used. No difference was found between TT-specific and nonspecific B cells in their capacity to present PPD to a PPD-specific T-cell line (Fig. 1*g–i*).

To test the possibility that secreted antibodies contribute to the high efficiency of antigen presentation by specific B cells, monoclonal anti-TT IgG was purified from the culture supernatants of the B-cell clones and added at different concentrations to cultures containing TT-specific T-cell clones and nonspecific B cells. In no case was any significant increase in the efficiency of presentation of TT observed (Fig. 1*c*). From the above experiments, we conclude that surface immunoglobulin molecules have a role in antigen uptake and concentration on specific B cells, allowing them to cooperate preferentially with specific T cells in the presence of minute amounts of antigen.

To investigate whether specific T/B-cell cooperation, like antigen presentation by macrophages or nonspecific B cells[3,5], is MHC-restricted, TT-specific B cells were compared for their ability to present TT to autologous or allogeneic TT-specific T-cell clones. TT-specific B cells were unable to present TT to allogeneic T cells even in the presence of concentrations of antigen 10^4 times higher than those required for presentation to autologous T cells (Fig. 2*a*). Furthermore, monoclonal anti-HLA-DR antibody quantitatively inhibited antigen presentation (Fig. 2*b*). We conclude, therefore, that these antigen-specific T/B-cell interactions are MHC-restricted.

Macrophages and nonspecific B cells must usually first internalize and process a complex protein antigen before presenting it to T cells[4,6]. However, it was possible that specific B cells could bypass this step and present protein antigens bound externally to immunoglobulin receptors. We therefore tested the effect of anti-immunoglobulin antibodies on antigen uptake and presentation by specific B cells. The addition of anti-immunoglobulin to B cells before pulsing with limiting concentrations of TT effectively reduced their subsequent capacity to stimulate T cells (Table 2, expt 1), the same treatment resulting in an 80% inhibition of uptake of ^{125}I-TT (data not shown). However, when anti-immunoglobulin was added after TT, no inhibition was observed, indicating that these antibodies interfere only with the uptake but not with the subsequent antigen presentation to T cells. We next tested the effect of chloroquine treatment, which inhibits intracellular antigen processing[9], followed by glutaraldehyde fixation to prevent any further processing[10]. Table 2 (expt 2) shows that glutaraldehyde-fixed TT-specific B cells were able to present native TT to TT-specific T cells only if the B cells had been pulsed with TT before fixation. Unpulsed glutaraldehyde-fixed B cells did not present soluble TT, even though they could still bind ^{125}I-TT. If chloroquine was added during the antigen pulse, the ability of TT-pulsed B cells to stimulate T cells was completely abrogated. None of the above treatments, however, affected the capacity of B cells to present an alloantigen to a specific alloreactive T-cell clone. These data indicate that a chloroquine-sensitive intracellular step is required for antigen presentation and that the role of surface immunoglobulin is limited to antigen uptake.

Our finding that specific B cells can present TT to T cells at free antigen concentration ~10^4 times lower than required for presentation by nonspecific B cells or peripheral blood monocytes[11] agree with results reported by Rock *et al.* using a hapten–carrier conjugate and hapten-specific normal B cells[7]. These experiments provide direct quantitative evidence for the role of surface immunoglobulin in concentrating antigen on specific B cells and suggest that this may be the basis of clonal selection in the specific antibody response to low antigen concentrations. Furthermore, our data obtained with a monovalent protein antigen show that selective interaction can occur at antigen concentrations far lower than the affinity constant of the antibody, that is, in conditions where only a very small

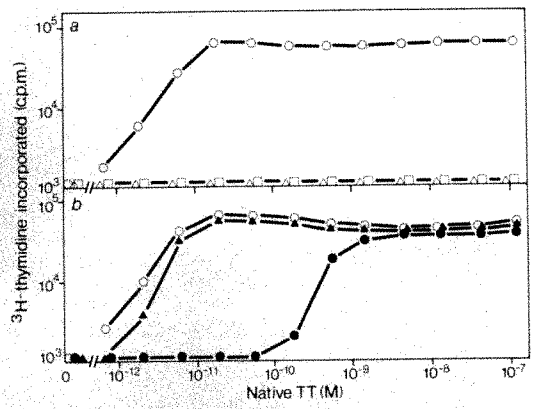

Fig. 2 Antigen presentation by antigen-specific B cells is MHC-restricted. *a*, A TT-specific B-cell clone (11.3) was irradiated and cultured in the presence of different concentrations of TT with an autologous TT-specific T-cell clone, KT1 (○), or with allogeneic TT-specific clones AT1 (□) and FT4 (△). The latter clones, obtained as described in Fig. 1 legend from two donors unrelated to K.K., incorporated in parallel experiments >30,000 c.p.m. when stimulated by TT in the presence of autologous APC (data not shown). *b*, TT-specific T and B cells (clones KT4 and 11.3) were stimulated with TT in the presence of anti-HLA-DR monoclonal antibody D1.12 at 10 μg ml^{-1} (●), anti-HLA-A,B,C antibody W6/32 at 50 μg ml^{-1} (▲) or medium alone (○). Culture conditions were as described in Fig. 1 legend.

fraction of surface immunoglobulin is occupied by antigen. It is possible that receptor internalization, by continuously removing antigen from the equilibrium, could lead with time to selective antigen accumulation in specific B cells.

The above experiments assayed T/B-cell interaction by measuring T-cell activation. We also have evidence that B-cell responses, such as increased antibody production and induction of terminal B-cell differentiation, can occur in the same system at the same antigen dose range. Thus, despite the limitations inherent in the use of EBV-transformed B cells and long-term T-cell clones, we feel that these data on antigen presentation are representative of T/B-cell cooperative interaction.

The requirement for antigen processing by specific B cells allows, in principle, all T cells selected by macrophage-processed antigen to interact with the same specificity with all antigen-specific B lymphocytes, independently of the hapten epitope recognized by the B cell. The requirement for processing may vary with the form of antigen used for stimulation[10], however, since the B-cell response is focused mainly against conformational determinants[8], which are easily lost on processing, it is likely that antigen processing by B cells will be a quite general rule. Antigen processing by B cells also easily explains the linked cooperation between two cells of different specificities. B cells bind soluble antigens by recognizing easily accessible conformational epitopes and, after intracellular processing of the antigen, will present to the T cells a different series of determinants similar to those produced by any nonspecific APC. This suggests that the antigen bridge is due to a sequential, rather than simultaneous, recognition of antigen by B and T cells.

Absence of growth by most receptor-expressing fetal thymocytes in the presence of interleukin-2

Harald von Boehmer, Andrea Crisanti, Pawel Kisielow & Werner Haas

Basel Institute for Immunology, Grenzacherstrasse 487, CH-4005 Basel, Switzerland

The growth of mature T cells is regulated by receptors for interleukin-2 (IL-2) and by IL-2 itself. Binding of antigen to T-cell antigen receptors induces the expression of IL-2 receptors, and binding of IL-2 to these receptors induces transferrin receptor expression and is sufficient to promote the growth of T cells for several days[1,2]. However, nothing is known about the growth requirements of pre-T cells. We have therefore studied the dividing population of T-cell precursors which carry the Thy-1 surface antigen, but lack surface antigens Ly2 and L3T4; these cells are present in 14-day-old embryonic thymus[3,4]. If the thymus is removed at this stage and placed in organ culture, all lymphocyte subpopulations normally present in thymuses of adult mice develop *in vitro*[4,5], that is, the nonfunctional Ly2$^+$, L3T4$^+$ population and the functional Ly2$^+$, L3T4$^-$ and Ly2$^-$, L3T4$^+$ populations[4]. We now report that, in contrast to their progeny, the early Ly2$^-$, L3T4$^-$ cells express large amounts of IL-2 receptors, but most of them do not grow in IL-2-containing media outside the thymus. In contrast to dividing mature T cells, most fetal thymocytes express low amounts of transferrin receptors.

We have analysed the expression of receptors for IL-2 and transferrin using monoclonal antibody 7D4, directed against IL-2 receptors[6], and antibody 34D2, directed against transferrin receptors. The 34D2 hybridoma was obtained in our laboratory, and the antibodies precipitate a disulphide-linked dimer, consisting of subunits of relative molecular mass 93,000 (93K) and inhibit the binding of radiolabelled transferrin to the EL4 thymoma (A.C., unpublished). Table 1 shows the proportion of IL-2-receptor-positive thymocytes at various stages of thymus development; >90% of 14-day-old embryonic thymocytes were IL-2-receptor positive whereas only about 5% of adult thymocytes were stained. Moreover, 15-day-old embryonic thymocytes which showed very strong staining with antibody 7D4, stained only weakly with the anti-transferrin receptor antibody 34D2 in contrast to cells from the IL-2-dependent line CTL-L16 (Fig. 1). As analysed by gel electrophoresis, antibody 7D4 precipitated the same molecular species from both the fetal thy-

Table 1 The proportion of IL-2-receptor-positive thymocytes at various stages of thymus development

Age	7D4 positive
14-Day embryonic	90%
15-Day embryonic	72%
16-Day embryonic	20%
21-Day postnatal	4%

Thymocytes from various donors were incubated with 7D4 antibodies, washed and stained with a fluorescein isothiocyanate (FITC)-labelled sheep anti-mouse immunoglobulin (kindly provided by Luciana Forni) which cross-reacts on rat antibodies. Stained cells were analysed by fluorescence-activated cell sorter (FACS) as described elsewhere[4] and shown in Fig. 1.

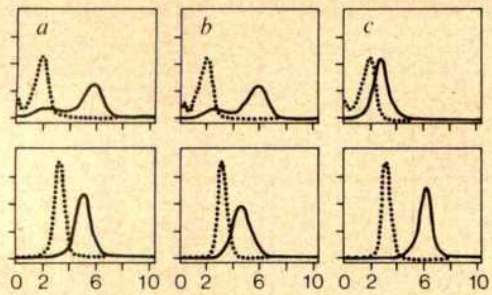

Fig. 1 Staining of 15-day-old embryonic thymocytes (top) and CTL-L16 cells (bottom) with anti-IL-2-receptor antibody 7D4 (hybridoma supernatant undiluted (*a*) and diluted 1:10 (*b*)) and anti-transferrin-receptor antibody 34D2 (undiluted supernatant (*c*)). Cells were incubated with antibodies at 0 °C, washed and stained with FITC-sheep anti-mouse immunoglobulin. Broken line, second antibody only.

mocytes and the CTL-L16 line (Fig. 2). We did not detect any IL-2 production by 15-day-old embryonic thymocytes[4] and, despite their expression of IL-2 receptors, fetal thymocytes did not grow outside the thymus in IL-2-containing media (Table 2).

The biological significance of IL-2 receptor expression by pre-T cells is obscure. As a first step towards an understanding, we may compare the results presented here with the data available on the induction and function of IL-2 receptors in mature T cells. First, IL-2 receptor expression by mature T cells is controlled by antigen receptors which are, at least in part, formed by two different ~45K polypeptide chains linked by disulphide bridges[7,8]. Although 15-day-old embryonic thymocytes do not express these antigen receptor molecules, which are detectable in two-dimensional gel analysis[9], they nevertheless express high levels of IL-2 receptors (Fig. 1). At present, however, we cannot exclude the possibility that only one of the α, β or γ polypeptide chains controls IL-2 receptor expression in fetal thymocytes. Second, IL-2, which induces growth in IL-2-receptor-expressing mature T cells, does not induce DNA synthesis in IL-2-receptor-expressing pre-T cells. Third, proliferating mature T cells express more transferrin receptors than do most fetal thymocytes. The low level of transferrin receptor expression by fetal thymocytes may be due to the lack of IL-2, which is required for transferrin receptor expression by mature T cells. The expression of IL-2 receptors in the absence of IL-2 may, in fact, be a signal for cell death and related to the finding that most newly formed thymocytes die *in situ*[10].

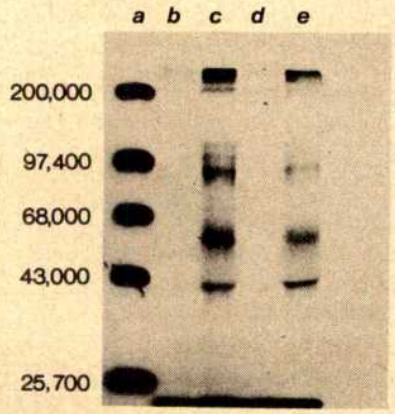

Fig. 2 Precipitation of the antibody 7D4 from lysates of CTL-L16 cells and 15-day-old embryonic thymocytes (pre-T cells). SDS-polyacrylamide gel electrophoresis (10%, reducing conditions) of material precipitated by antibody 7D4. The CTL-L16 line as well as 15-day-old embryonic thymocytes were labelled with ^{125}I using lactoperoxidase. NP40 lysates were precipitated with 7D4 or normal rat serum and rabbit anti-rat immunoglobulin. Lane *a*, relative molecular mass markers; lane *b*, CTL-L16 and rat serum; lane *c*, CTL-L16+7D4; lane *d*, pre-T cells+rat serum; lane *e*, pre-T cells+7D4.

Table 2 ^{3}H-thymidine incorporation by fetal thymocytes and CTL-L16

IL-2	15-Day-old embryonic thymocytes	CTL-L16
—	6,700	9,200
1,000 U ml^{-1}	6,900	115,400

Cells (10^5) were suspended in culture medium with or without IL-2 and ^{3}H-thymidine was added immediately. Incorporation of thymidine was measured after 24 h. After 48 h no viable thymocytes were detected. Recombinant IL-2 was obtained from Biogen[11].

We thank Dr E. Shevach and collaborators for the gift of antibody 7D4. P.K. is on leave of absence from the Ludwik Hirszfeld Institute of Immunology and Experimental Therapy of the Polish Academy of Sciences, Wroclaw, Poland. The Basel Institute for Immunology was founded and is supported by F. Hoffmann-La Roche & Co., Basel, Switzerland.

Sequence homology of the LFA-1 and Mac-1 leukocyte adhesion glycoproteins and unexpected relation to leukocyte interferon

Timothy A. Springer*, David B. Teplow† & William J. Dreyer†

* Laboratory of Membrane Immunochemistry, Dana-Farber Cancer Institute, Harvard Medical School, Boston, Massachusetts 02115, USA
† Division of Biology, California Institute of Technology, Pasadena, California 91125, USA

Cell-surface adherence reactions are fundamental to the biology of lymphocytes, monocytes and granulocytes. The lymphocyte function-associated 1 (LFA-1) and macrophage 1 (Mac-1) glycoproteins mediate differing types of adhesion reactions on these cells. LFA-1 participates in T-lymphocyte and natural killer-cell adhesion to target cells[1-3], whereas the Mac-1 antigen is identical to the complement receptor type 3, which mediates adhesion of monocytes and granulocytes to C3bi-sensitized particles[4]. Deficiency of these proteins, in a heritable disease, results in multiple adhesion-related leukocyte defects[5,6]. LFA-1 and Mac-1 resemble one another in overall structure, having α-subunits of relative molecular mass (M_r) 180,000 and 170,000, respectively, which are non-covalently associated with β-subunits of M_r 95,000 in $\alpha_1\beta_1$ complexes[7,8]. Peptide mapping and immunological cross-reactivity have shown that the β-subunits are highly related if not identical, but have revealed no similarities between the α-subunits[7,9,10]. Nonetheless, the shared β-subunit suggested that LFA-1 and Mac-1 might be members of a protein family containing diversified but evolutionarily related α-subunits. Therefore, we examine here the structure of the α-subunits by N-terminal amino-acid sequencing. Sequence homology shows that the α-subunits are members of a novel leukocyte adhesion protein family, and suggests that their evolution occurred by gene duplication. A search for similarities to previously sequenced proteins reveals a further unexpected homology between LFA-1 and leukocyte (α) interferons.

Fig. 1 N-terminal sequences of LFA-1 and Mac-1 α-subunits. Homologous sequences are boxed.

Methods. LFA-1 was purified from 10- or 50-g batches of EL-4 T lymphoma cells grown *in vitro*. Cells were lysed with Triton X-100, sodium deoxycholate was added before the ultracentrifugation step and LFA-1 antigen was bound to M17/4 monoclonal antibody-Sepharose and eluted at high *p*H, as described previously[8]. The eluate in 0.5% Triton X-100, 20 mM triethylamine *p*H 11.0, was neutralized by adding 0.075 vol. of 1 M Tris-HCl *p*H 6.8. Mac-1 from P388D$_1$ cells was purified similarly on M1/70 monoclonal antibody-Sepharose, except that the neutralized eluate was subjected to a second cycle of affinity purification. SDS-polyacrylamide gel electrophoresis (PAGE) and Coomassie brilliant blue staining of purified LFA-1 and Mac-1 demonstrated that the α- and β-subunits had no contaminants, as shown previously[7,10]. Purified antigens were reduced with 20 mM diothiothreitol, alkylated with 50 mM iodoacetic acid and precipitated overnight at −20 °C with 1.5 vols 1% acetic acid in methanol. Precipitates were collected at 200,000 *g* for 0.5 h and subjected to preparative SDS-PAGE. Subunits were localized by Coomassie brilliant blue staining, electroeluted[17] and subjected to gas/liquid solid phase microsequencing[18]. Phenylthiohydantoin amino acids were determined by HPLC[19]. The sequence assignments shown were confirmed by multiple determinations. The α-subunit of LFA-1 from two different purifications was sequenced three times (200, 44 and 22 μg) and the α-subunit of Mac-1 was sequenced twice (63 and 31 μg). Residues in parentheses were found together with smaller amounts of another residue, or in low yield. No sequence was obtained from the LFA-1 and Mac-1 β-subunits, suggesting that they are blocked.

We purified murine LFA-1 and Mac-1 antigens by monoclonal antibody affinity chromatography from detergent lysates of EL-4 T-lymphoid and P388D$_1$ macrophage-like cell lines and separated the α-and β-subunits (see Fig. 1 legend). The N-terminal sequences of the LFA-1 and Mac-1 α-subunits are 33% homologous (Fig. 1). Four contiguous amino acids are identical at positions 2–5 and further identities occur at positions 11 and 15. Some of the differences represent relatively conservative amino-acid substitutions, namely Phe for Tyr at residue 1, Thr for Ser at 10, and Asp for Glu at 14. If a gap was introduced before the Lys at position 16 in Mac-1, it would be aligned with an Arg in LFA-1 and Phe at positions 18 and 19 would be aligned.

The sequence homology shows that the α-subunits constitute a novel adhesion protein family, the genes of which evolved by duplication of a primordial ancestral gene. The N-terminal sequences have diverged considerably since the primordial gene duplication event. These differences suggest that the specificity in adhesive interactions is determined by the α-subunits, in agreement with localization of a binding site of the C3bi antigen on the α-subunit of Mac-1 using α- and β-subunit-specific monoclonal antibodies[10,11]. Duplication and specialization of the α-subunits must have preceded divergence of mouse and human, as LFA-1 and Mac-1 homologues mediating the same functions occur in humans[12]. A third type of human α-subunit has been identified[12] which may represent a further member of the α-subunit protein family. The amino-acid sequences described here allow the specification of oligonucleotide probes, which should be of use in the isolation and further study of the Mac-1/LFA-1 family of α-subunit genes.

Table 1 Homology between LFA-1, Mac-1 and interferons

	% Identity				
	Mac-1	Rodent IFN-α	Human IFN-α	IFN-β	IFN-γ
LFA-1	33	32	35	26	5
Mac-1	—	15	7	3	6
Rodent IFN-α	—	—	55	20	0
Human IFN-α	—	—	—	27	1
Murine and human	—	—	—	—	5

The numbers refer to the percentage homology between the sequences depicted in Figs 1 and 2. Homologies between residues 7–25 of the mouse and human interferons were calculated and averaged in the groups shown.

A computer search[13] for homologies with other proteins reveals an unexpected, strong homology between LFA-1 and human leukocyte interferon (Fig. 2). Multiple genes for α-interferon (IFN-α) code for a family of closely related interferon proteins[14]. Comparison of LFA-1 with 12 mouse, rat and human α-interferons reveals homology of LFA-1 with all of them (Fig. 2). Note that the LFA-1 and IFN-α sequences align without any gaps. IFN-α shows ~30% homology to fibroblast interferon (IFN-β). LFA-1 shows a lesser degree of homology with IFN-β (Fig. 2). The homologies with IFN-α are highly statistically significant (Fig. 2).

Homology with LFA-1 occurs in different positions in rodent and human IFN-αs. Despite the higher homology of LFA-1 to human IFN-α1 than to any other interferon, an additional homology found exclusively with rodent IFN-α occurs at residues 1 and 2 in LFA-1 (Fig. 2). Also, conserved substitutions occur at many positions, including 10 and 11, where no identities are found. These findings further strengthen the homology between LFA-1 and IFN-α.

The homology among LFA-1, Mac-1 and the interferons is summarized in Table 1. Mac-1 and LFA-1 are about as homologous with one another as is LFA-1 with IFN-α. The significance of the 32–35% homology between LFA-1 and IFN-αs is emphasized by the fact that it is stronger than the 20–27% homology observed between IFN-α and IFN-β in the segments compared with LFA-1, or the homology of 29% along the total lengths of IFN-α and IFN-β[15]. Furthermore, the homology between LFA-1 and the α- and β-interferons is stronger than the homology between IFN-γ and the α- and β-interferons.

Our findings suggest that the LFA-1/Mac-1 α-subunit family and the interferon family arose from a single ancestral gene and can be considered as a superfamily. This is remarkable for

Fig. 2 Sequence homology between LFA-1 and interferons. Residues homologous between interferons and LFA-1 are boxed; homologies with Mac-1 are italicized. α-, β- and γ-interferon sequences[14,20,21] were aligned as described previously[22,23]. Asp 25 of IFN-β was deleted for alignment[22]. The right-hand column describes the percentage probability that homology results from chance alone, as determined by summation of the log odds of each amino-acid pair derived from the mutation data matrix of Dayhoff[24].

several reasons. First, LFA-1 and Mac-1 are surface receptors, whereas the interferons are secreted mediators. Second, there are striking differences in size. The LFA-1 and Mac-1 α-polypeptide chains (M_r 180,000 and 170,000) are roughly 10 times longer than those of the interferons ($M_r \sim 20{,}000$). Despite the difference in size, the N-terminal sequence of LFA-1 aligns only six residues away from the N-terminus of IFN-α. A common evolutionary mechanism for obtaining large proteins is tandem duplication and joining of domains. Further sequencing of LFA-1 is needed to determine whether it contains the homologue of an entire interferon domain and whether it contains duplications of these domains.

It is tempting to speculate that the LFA-1/Mac-1/interferon superfamily could have functional as well as structural interrelationships. All of these molecules function in cell interactions of the host defence system. Unlike the immunoglobulin superfamily[16], none of them is involved in specific antigen recognition and their importance in host defence could have pre-dated the evolution of specific immunity.

We thank Dr R. Doolittle for homology searches with the NEWAT data base and Mr S. Thompson for technical assistance in protein purification. This work was supported by NIH grants CA-31798, CA-31799, and GM-06965 and an American Cancer Society faculty award to T.A.S.

Isolation and characterization of a cDNA clone encoding the murine homologue of the human 20K T3/T-cell receptor glycoprotein

Peter van den Elsen, Beth-Ann Shepley, Mildred Cho & Cox Terhorst

Laboratory of Molecular Immunology, Dana-Farber Cancer Institute, 44 Binney Street, Boston, Massachusetts 02115, USA

The antigen receptor on the surface of human T lymphocytes, which consists of a heterodimer of relative molecular mass (M_r) 90,000 (90K) (α- and β-chains), is associated with the T3 antigen ($\gamma = 25$K, $\delta = 20$K and $\varepsilon = 20$K)[1-7]. A working model for the mode of action of the T3/T-cell receptor complex is that the clonotypic α- and β-chains are involved in the recognition and binding of antigen in the context of polymorphic major histocompatibility complex (MHC) gene products on the surface of target cells. Antigen binding by the clonotypic receptor probably results in conformational changes in this structure which are recognized by and subsequently trigger the associated T3 complex to transmit signals into the cell, resulting in a proliferative response[8-10]. The similarity in structure between murine and human clonotypic antigen receptors[11-15] suggests that such a mechanism of recognition and activation also exists in mouse T lymphocytes, but so far there has been no evidence for the existence of a murine T3 complex. Here we demonstrate the existence of a T3δ-chain mRNA in murine T lymphocytes. Our sequence data strongly suggest that this mouse mRNA codes for a complete T3δ polypeptide chain and reveal some interesting properties of the protein.

The cDNA clone pPGBC-9, which contains a full-length cDNA copy coding for the human T3δ-chain[16], was used here to examine a series of murine T-cell lines for expression of RNA coding for the murine equivalent of the T3δ-chain; only in mouse T cells was a 0.7-kilobase (kb) mRNA observed (data not shown). From one of these cells, B3C6, an anti-Ia T-T hybridoma,[17] we isolated poly(A)$^+$ mRNA, which was used to construct a cDNA library in the bacteriophage λgt10 (refs 18, 19). This library was then screened with the cDNA insert of the human T3δ cDNA clone pPGBC-9 at low stringency. Ten plaques out of $\sim 2.5 \times 10^5$ were found to hybridize with pPGBC-9. On plaque purification and rescreening at low stringency, only two plaques remained positive. The cDNA inserts of these two overlapping phages were 200 and 640 base pairs (bp) long, respectively. The 640-bp insert of phage λ PEM-T3δ was isolated and subcloned into the *Eco*RI site of the plasmid vector SP65 (ref. 20) (that is, cDNA clone pPEM-T3δ). The nucleotide sequence of clone pPEM-T3δ was determined by the Maxam-Gilbert method[21]. Figure 1 shows the sequencing strategy and the resulting 570-nucleotide-long sequence of the cDNA insert of pPEM-T3δ. Only one open reading frame is present in this sequence, which ends with a termination codon, TAA, at position 490. No initiation codon was detected. Comparison of the size of the cDNA insert with the size of the T3δ mRNA detected in a Northern blot (data not shown) and comparison with the human T3δ cDNA (Fig. 1*b*) indicates that this cDNA does not represent a full-length transcript of the murine T3δ mRNA. Alignment with the human cDNA sequence (Fig. 1*b*) and the presence of a polyadenylation signal, AATAAA, followed by a poly(A) tail 19 nucleotides downstream, shows that pPEM-T3δ contains the entire 3′ noncoding region and lacks some of the 5′ sequences.

We have shown previously that in human the T3δ mRNA is present in cells of the T lineage only[16]. On Northern blot analysis with the murine clone pPEM-T3δ cDNA, mRNA was detected in T cells and thymocytes, but not in L-cells, liver cells or a B-cell hybridoma (data not shown). This suggests that the murine T3δ-chain also is expressed exclusively in thymus-derived lymphocytes.

The PROTALN and NUCALN (IntelliGenetics, Inc.) programs[22] revealed no homology between the murine T3δ-chain and T-cell receptor structures, immunoglobulin or Thy-1. In addition, a search of the Dayhoff database using the Wilbur-Lipman algorithm[22,23] did not reveal homology with any known protein.

Comparison of the amino-acid sequences of the human and murine T3δ polypeptide chains showed that they are very similar. Alignment of the amino-acid sequences revealed that the murine T3δ cDNA clone (pPEM-T3δ) codes for only part of the leader sequence (Fig. 2). Furthermore, the mature protein has two additional amino acids at its C-terminus (Lys and Ser). The mature murine T3δ-chain therefore consists of 152 amino acids with a deduced M_r of 16,905 and is slightly larger than its human equivalent (M_r 16,719). The domain organization of the murine T3δ-chain, derived from its hydropathicity profile[24], is very similar to that of the human T3δ-chain (Fig. 3). A 79-residue extracellular domain is followed by a transmembrane

Fig. 1 *a*, Partial restriction map of the murine T3δ-chain and strategy for sequencing of clone pPEM-T3δ. The restriction enzymes used were *Eco*RI, *Xba*I, *Hin*fI, *Dde*I and *Taq*I. Open circles represent 5′-labelling; the closed circle represents 3′-labelling for Maxam-Gilbert sequence analysis. *b*, Comparison of the nucleotide sequences of murine and human T3δ-chain. The 570-nucleotide-long sequence of clone pPEM-T3δ (mouse T3δ) is compared with the 700-nucleotide-long sequence of clone pPGBC-9 (human T3δ). For the alignment we used the NUCALN (IntelliGenetics, Inc.) program. Identical nucleotides are indicated by double dots. The ATG initiation codon in the human T3δ sequence, and the codon coding for the first amino acid of the mature protein (Phe) and termination codon of both human and murine T3δ are indicated by arrows.

Methods. The murine B3C6 cDNA library constructed in phage λgt10 was screened with the cDNA insert of clone pPGBC-9. Approximately 2.5×10^5 plaques were generated and plaque lifts were made on nitrocellulose filters as described elsewhere[27]. The filters were prehybridized at 42 °C in 50% deionized formamide, 5×SSC (1×SSC = 0.15 M NaCl, 0.015 M Na_3-citrate), 5× Denhardt's solution (1×Denhardt = 0.02% Ficoll 400, 0.02% bovine serum albumin and 0.02% polyvinylpyrrolidone), 50 mM sodium phosphate (pH = 6.5), 0.1% SDS and 250 μg ml^{-1} of denatured salmon sperm DNA. Hybridization was carried out in the same buffer for 16 h at 42 °C. The human T3δ-chain cDNA insert of clone pPGBC-9 (ref. 16), ^{32}P-labelled by nick-translation (specific activity $2\text{–}5\times10^8$ c.p.m. μg^{-1}), was used as hybridization probe at 5×10^6 c.p.m. ml^{-1}. After hybridization, the filters were washed three times in 250 ml of 2×SSC plus 0.1% SDS at room temperature, and twice in 250 ml of 2×SSC plus 0.1% SDS at 50 °C for 15–20 min each. The filters were air-dried and exposed to Kodak XAR-5 film at −70 °C using an intensifying screen. Positive plaques were purified by one additional cycle of screening. Single plaques were isolated and amplified through *Escherichia coli* KM392, followed by a medium-scale phage preparation as described previously[27]. Phage DNA was prepared according to standard procedures[27], digested with *Eco*RI and the generated insert was isolated from 0.8% agarose slab gel by adsorption to activated glass[28]. Plasmid SP65 (ref. 20) was linearized with *Eco*RI and the ends were treated with calf intestinal phosphatase to make it suitable as cloning vehicle[29]. Vector and cDNA insert were mixed in a 1:2 molar ratio, followed by ligation in the presence of 1 mM ATP and 10 units of T4 ligase for 13–16 h at 16 °C. Part of the ligation mixture was used to transform *E. coli* MC1061 (ref. 30) to ampicillin resistance. Recombinants were isolated, identified and grown in large cultures using standard techniques[27]. Plasmids were purified through CsCl gradients[27]. Purified cDNA insert was digested with *Xba*I, *Hin*fI, *Taq*I and *Dde*I, and the generated ends were labelled either at their 5′ ends with T4 polynucleotide kinase and [γ-^{32}P]ATP or at their 3′ ends with DNA polymerase I (Klenow fragment) and [α-^{32}P]dNTPs. The labelled fragments were separated by electrophoresis in a 5% polyacrylamide gel and the individual fragments were isolated and purified[21]. These fragments were subsequently treated with a buffer containing 30% (v/v) dimethyl sulphoxide and 1 mM EDTA for 3 min at 90 °C and run through a strand-separating gel[21]. Single strands were isolated, purified and subjected to chemical degradation as described by Maxam and Gilbert[21].

segment (residue 80–106) and a cytoplasmic domain (residues 107–152). A high level of amino-acid sequence conservation is apparent both in the transmembrane (70.4%) and intracellular (77.2%) domains of murine and human T3δ-chain. Much less homology was found in the extracellular domains (58.2%).

The locations of the five cysteines (residues 16, 52, 72, 75 and 103) and two attachment sites for Asn-linked oligosaccharides (residues 17 and 53) are conserved (Figs 2, 3). The murine T3δ-chain, however, contains a third site for Asn-linked glycans at residue 34. The existence of this third consensus sequence (Asn 34–Lys 35–Thr36) for *N*-linked glycosylation in the murine T3δ-chain suggests that the mature glycosylated murine T3δ-chain has a higher relative molecular mass than its human equivalent. The attachment of three oligosaccharide moieties to a relatively short extracellular domain (79 residues) might decrease the immunogenicity of the murine T3δ; this could explain why attempts to prepare rat monoclonal reagents specific for murine T3 have been unsuccessful. The amino-acid sequences around Asn 34 are very different from those in the human polypeptide chain. This suggests that murine anti-T3 monoclonal antibodies recognize a determinant which is located between residues 20 and 39 in the human T3δ-chain. As this area of the molecule carries an oligosaccharide in the murine chain, this putative determinant is probably also located on the surface of the human protein. The existence of an easily accessible determinant on the surface of the human molecule would

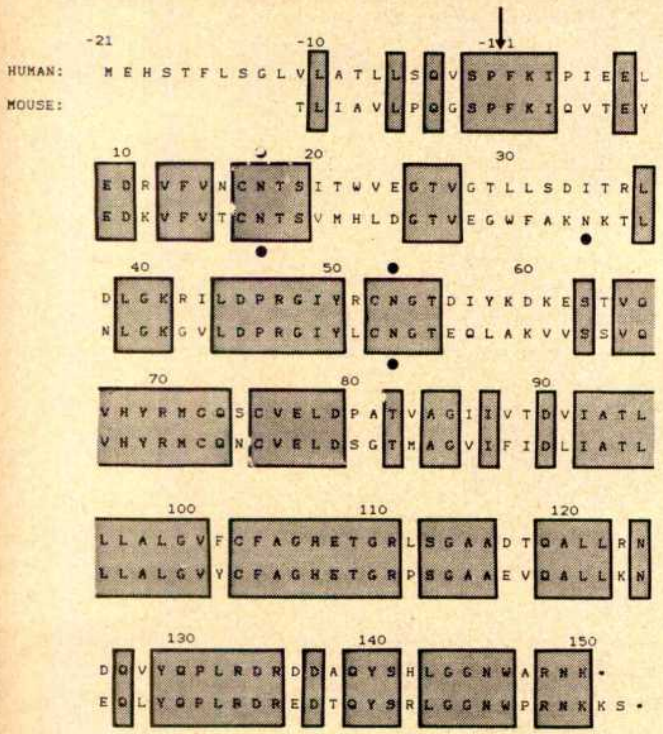

Fig. 2 Comparison of the amino-acid sequences of murine and human T3δ-chain. The vertical arrow above the sequence indicates the first amino acid of the mature protein. Identical amino acids are boxed. The potential attachment sites for asparagine-linked glycosylation are indicated by solid circles.

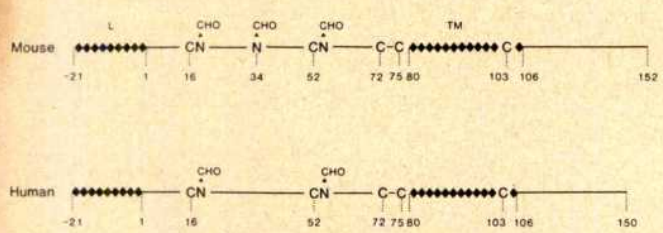

Fig. 3 General features of the organization of the murine and human T3δ-chain. L represents the leader peptide sequence, which is presumably 21 amino acids long in murine T3δ-chain, and TM represents the transmembrane domain. C, cysteine residues; CHO, *N*-linked glycosylation sites.

explain why murine anti-T3 monoclonal antibodies have been prepared with a relatively high frequency.

Of interest is the conservation of the aspartic acid residue at position 90 in the transmembrane domain (Fig. 2). This amino acid could be involved in a salt bridge with the lysine or arginine residues present in the transmembrane segment of the T-cell receptor α- and β-chains (Fig. 4)[14,15,25,26]. The hydrophobic environment may enhance the stabilizing effect of this salt bridge on the protein/protein interactions between the T3δ-chain and the α- and β-chain of the T-cell receptor. Such interaction depends, of course, on the precise positioning of the charged residues.

Thus, we have identified the murine homologue of the T3δ-chain. This finding, together with the similarity in structure of the T-cell receptor α- and β-chains, predicts that murine γ- and ε-chains will be found also. The availability of a cDNA clone coding for the murine T3δ-chain will allow the generation of anti-peptide antibodies, which will be useful in studies of the T3/T-cell receptor complex on the surface of antigen-specific mouse T cells. Furthermore, these antibodies, together with the DNA probes, will allow us to correlate transcriptional activity with cell-surface expression of these cell-surface structures within the thymus. This knowledge should further our understanding of the regulation of the function of the T3/T-cell

An unusual type of *V–J* joining diversifies the primary repertoire of mouse λ1 light chains

Klaus Karjalainen* & Christopher Coleclough†

* Basel Institute for Immunology, Grenzacherstrasse 487, CH-4005 Basel, Switzerland
† Roche Institute of Molecular Biology, Nutley, New Jersey 07110, USA

It is well established that B lymphocytes can achieve an almost unlimited antibody repertoire by using combinations of at least three different basic mechanisms[1]. First, the mammalian genome has multiple, distinct germline variable (*V*), joining (*J*) and diversity (*D*) gene segments which can presumably combine randomly to give *V–D–J* joins in the heavy (H)-chain loci and *V–J* joins in the light (L)-chain loci during the formation of functional antibody genes. Second, the actual joining points between any two

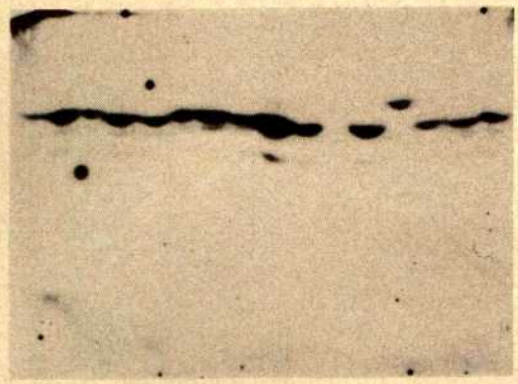

Fig. 1 IEF analysis, which shows one variant λ1 light chain. To obtain the λ1-chain-containing supernatants, normal spleen cells from (BALB/c × NZB)F_1 mice were cultured in the presence of 50 μg ml^{-1} LPS (*Salmonella typhosa* 0901, Difco) in RPMI medium supplemented with 20% fetal bovine serum, 5×10^{-5} M 2-mercaptoethanol and 50 μg ml^{-1} gentamycin. The initial cell concentrations were 5×10^5 ml^{-1} and 3×10^4 ml^{-1} for day 3 and day 8 cultures respectively. Stimulated cells were fused with Sp2-0 plasmacytoma cells using standard procedures[6]. When 10^8 fused cells were plated into 20 96-well microtitre plates, multiple clones grew in individual wells. Cells from those wells that showed a positive reaction with a monoclonal rat anti-mouse λ1 antibody (4/1-101)[3] were subcloned, and the supernatants from these λ1-positive subclones were subjected to IEF analysis. The supernatants were mildly reduced with dithiothreitol (10 mM, 15 min at room temperature) followed by alkylation with 2× molar excess of iodoacetamide (30 min at room temperature). Just before loading, a fourfold volume of IEF sample buffer (9.5 M urea and 2% ampholine *p*H 3.5–10) was added to the supernatants. Usually ~40 μl of solution was applied per lane to 0.8-mm-thick 5% polyacryalamide slab gels (model V-16-2; BRL) containing 9.2 M urea and 2% ampholine *p*H 3.5–10. After overnight focusing at 200 V, the proteins were electrophoretically transferred to nitrocellulose filters using Western blot conditions[7], then the nitrocellulose filters were incubated in blocking solution (1% casein, 50 mM Tris-HCl *p*H 8.0, 150 mM NaCl) for 1 h at room temperature. Finally, λ1 light chains were detected using iodinated anti-λ1 monoclonal antibody, with subsequent autoradiography of the washed filters.

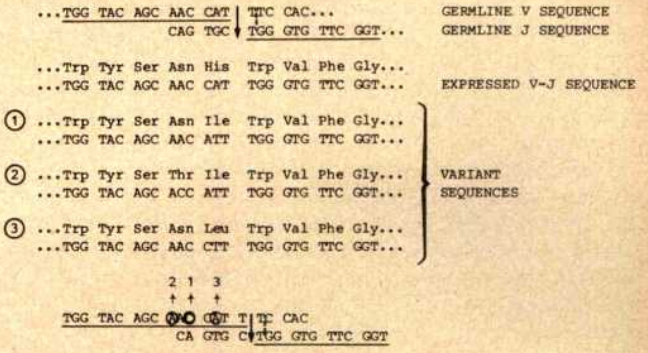

Fig. 2 The *V–J* join most frequently found is shown at the top, with the coding sequences of the *V* and *J* gene segments prior to rearrangement underlined. This 'germline' λ1 join can be compared with those of the variants, whose sequences were determined. All three variants have an extra T residue inserted at the *V–J* junction, and this is compensated for by the deletion of a single residue (circled nucleotides at the bottom) in the adjacent *V* sequence.
Methods. A double-stranded *Sac*I/*Kpn*I restriction fragment (75 base pairs (bp) long) corresponding to the 5′ portion of the λ1 constant-region gene was excised from the complementary DNA clone[8] pABλ1-15 (obtained from Dr A. Bothwell) and used as a primer. Total cytoplasmic RNA (50 ng) and the 5′ end-labelled primer (200 ng) were mixed in a 100-μl volume of annealing buffer (80% dimethylformamide, 400 mM NaCl, 40 mM PIPES *p*H 6.4, 1 mM EDTA) and incubated at 47.5 °C for 90 min. Annealing was stopped by diluting the mixture fourfold with 0.3 M sodium acetate and by precipitating nucleic acids with ethanol. The resultant pellet was dissolved in standard reverse transcription buffer and primer extension carried out using established conditions for reverse transcription[9]. Full-length cDNA was isolated on denaturing 5% polyacrylamide gels, and the sequence of the gel-purified material was determined according to the method of Maxam and Gilbert[10].

combining gene segments can vary considerably, increasing the germline diversity. Further variability is generated in the heavy-chain locus by *de novo* addition of extra nucleotides between the combining gene segments. Finally, somatic mutations independent from joining events can accumulate in *V* regions during the lifetime of B lymphocytes. Here we report that when *V* and *J* regions join in the formation of functional λ1 light-chain genes, 'lethal' out-of-frame joins can be compensated for by the deletion of nucleotides several bases upstream of the actual joining points; this generates small stretches of nucleotides in a new frame between the deletion and the *V–J* joining point, thus creating additional diversity in the third hypervariable regions of the mouse λ1 light chains.

In order to be able to study the mechanisms which generate diversity in the variable regions of mouse antibodies, we decided to minimize the complexity of the experimental system in two ways. First, we concentrated on λ1 light chains because the inherited repertoire of λ1 genes contains only one *V* region whose sequence is known[1]; thus, any different sequences found must result from somatic mutation. Second, we studied only virgin primary B cells and not, for example, immune cells, so that the frequency of variants observed would reflect as closely as possible the true frequency of somatic variation. To do this we stimulated normal spleen cells from (BALB/c × NZB)F_1 mice with bacterial lipopolysaccharide (LPS) which triggers the proliferation of virgin mouse spleen B cells[2]. Stimulated cells were then immortalized by fusion with Sp^2-0 plasmacytoma cells after 3 or 8 days of *in vitro* culture.

We obtained 101 and 113 λ1-secreting clones, as defined by their reaction with rat monoclonal anti-mouse λ1 antibody 4/1-101, (ref. 3), from day 3 and day 8 fusions, respectively. Ninety-five per cent of the day 3 but only 40% of the day 8 clones were IgM producers, showing that our culture conditions, like the limiting dilution cultures described by others[4], allowed the immunoglobulin switch to occur. To detect variants, we used isoelectric focusing (IEF) analysis as a primary screen; although this method underestimates the DNA sequence variability, the IEF method that we developed made it easy to analyse hundreds of supernatants (see Fig. 1 legend). We found four IEF variants among 213 λ1 chains studied (~2%). (Figure 1 shows an example of a primary screen that revealed one variant.) All four variants had similar IEF patterns; these were one charge unit more acidic than the wild-type pattern. The variants seemed to represent a random subpopulation of the whole sample of 213 λ1-secreting clones: two originated from the day 3 fusion, being of IgM type, and of the two day 8 clones, one had switched to IgG.

We determined the DNA sequences of three of the variants and of one wild type by using the primer extension technique (see Fig. 2 legend). It was immediately apparent from the sequence data that the variants were the products of a novel kind of joining mode. All of them had an extra T nucleotide at the *V–J* junction compared with the most frequent *V–J* join (Fig. 1). To maintain the correct reading frame, a compensatory deletion of one base had occurred 2, 4 and 6 nucleotides upstream of the 'inserted' T residue; as a result, only a small stretch of nucleotides was out-of-frame between the deletion and the insertion. In the most extreme case (variant 2) the DNA sequence encodes two new amino acids, Thr-Ile, at positions 95 and 96 compared with the wild-type sequence (Asn-His). The switch from the basic amino acid His to the neutral Ile or Leu (His is positively charged at the isoelectric point of the λ1 light chain, *p*I ~4.5) in these variants explains the acidic shift in their IEF pattern. No other mutations were found when about 80% of the *V* regions of the variants were sequenced (data not shown).

Explanations of the *V–J* joining mechanism must be consistent with the above findings. The extra T at the *V–J* junction is probably derived from the region just 3′ of the λ1 *V* region (see Fig. 2), that is, the recombination point is moved by one nucleotide. To explain the deletions upstream of the actual join, we speculate that *V–J* recombinations have error-prone sealing and repair activities. We do not know how frequently small deletions accompany the joining process nor do we know whether the deletions can occur also at the 3′ side of the junction because we have analysed only a selected subpopulation of λ1 chains. Certainly, the one-base deletion does not always occur when an extra T is added at the *V–J* join. An aberrantly rearranged λ1 light-chain gene having an 'extra T' but lacking the one-base deletion has been described[5].

Clearly, more data are needed to establish whether the mechanism described here is an impotant source of diversity in antigen receptors which are formed by the joining of two separate gene segments.

We thank Carolyn Tschachtli for preparation of the manuscript, and Drs David Nemazee and Siegfried Weiss for critical reading and comments. The Basel Institute for Immunology was founded and is supported by F. Hoffmann-La Roche & Co., Basel, Switzerland.

Induction of c-*fos* during myelomonocytic differentiation and macrophage proliferation

Rolf Müller, Tom Curran*, Dagmar Müller & Larry Guilbert

Previous studies have suggested a role for c-*fos* in cellular differentiation in fetal membranes[1–3], haematopoietic cells[4,5] and teratocarcinoma stem cells[6]. In other cell types, such as fibroblasts, c-*fos* expression is normally very low, but is rapidly induced by peptide growth factors, implicating c-*fos* in growth control mechanisms[7–10]. Here, we show that the TPA (12-*O*-tetradecanoylphorbol-13-acetate)-induced macrophage-like differentiation of HL60 human promyelocytic precursor cells[11,12] is accompanied by the induction of both c-*fos* mRNA and protein within 15 min after treatment, suggesting a functional role for c-*fos* in this differentiation system. In quiescent terminally differentiated macrophages, expression of c-*fos* is inducible by the macrophage-specific growth factor colony-stimulating factor-1 (CSF-1)[13]. The kinetics of c-*fos* induction, however, are entirely different from those in growth factor-stimulated fibroblasts, supporting the view that the c-*fos* gene product may serve different functions in different cell types.

The human promyelocytic leukaemia cell line HL60 (ref. 11) can be induced by the tumour promoter TPA to differentiate into macrophage-like cells[12]. Previously, it has been shown that this differentiation is associated with a drastic reduction in the level of expression of c-*myc* mRNA[5,14] and an increase in the level of c-*fos* mRNA[5] at a time when differentiation is almost complete (that is, 48 h after induction). To investigate a possible involvement of c-*fos* in the induction of differentiation, the time course of c-*fos* expression following TPA treatment of HL60 cells was followed in detail. Figure 1*a*,*b* shows that c-*fos* mRNA was not detectable in normal HL60 cells, but treatment with 5×10^{-7} M TPA induced c-*fos* expression within 15 min. Maximum expression was observed 30–45 min after addition of TPA; thereafter, the level of c-*fos* mRNA decreased 3–5-fold and remained at this level for the following 48 h. In contrast, expression of c-*myc* mRNA did not change until 4 h after TPA addition, when expression fell by more than 20-fold (Fig. 1*a*).

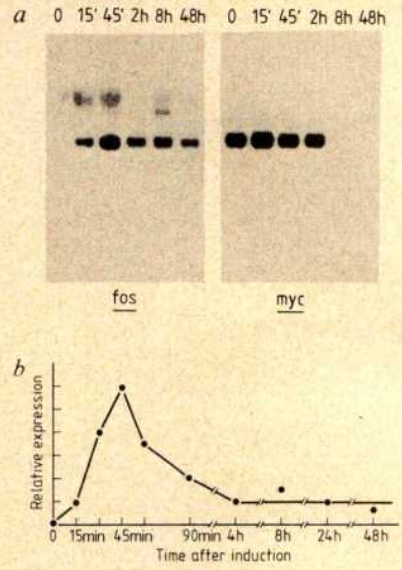

Fig. 1 Expression of c-*fos* and c-*myc* in TPA-induced differentiating HL60 cells. *a*, Northern blot analysis of total RNA (16 μg per lane) isolated at the indicated times after induction by 5×10^{-7} M TPA. Methods as described elsewhere[8]. Hybridization to v-*fos* and mouse c-*myc*-specific probes was performed as described[8]. *b*, Relative expression of c-*fos* plotted against time after TPA treatment. Quantitative evaluation of the Northern blot autoradiograms (similar to that shown in *a*) was done by comparing band intensities.

Differentiation of HL60 cells can also be induced by compounds other than TPA. A vitamin D_3 dihydroxy derivative, $1,25(OH)_2D_3$, induces monocyte differentiation[15], whereas treatment with retinoic acid gives rise to granulocytic cells[16]. In both cases, however, rapid induction of c-*fos* mRNA was not detectable (data not shown). In another study[4], it was reported that granulocyte–colony stimulating factor(G-CSF)-induced mouse myelomonocytic precursor cells express c-*fos* only at late stages of differentiation (that is, >2 days after induction). Taken together, these observations show that c-*fos* expression at an early stage is not an obligatory step in the differentiation of myelomonocytic or granulocytic cells. Rapid induction of c-*fos* expression seems to be specific for the TPA-induced pathway of monocytic differentiation.

Because c-*fos* protein has not yet been detected in human cells, we investigated whether the rapid induction of c-*fos* mRNA expression is associated with induction of c-*fos* protein, by immunoprecipitation of ^{35}S-labelled proteins from HL60 cells induced by TPA for various times. We used an antiserum directed against a synthetic peptide (designated 'M') common to v-*fos* and both mouse and human c-*fos* sequences[17]. It has been shown previously that this antiserum detects modified c-*fos* protein of relative molecular mass M_r 57,000–62,000 (57–62 K) which is complexed with a cellular protein, p39 (refs 8, 17–19;

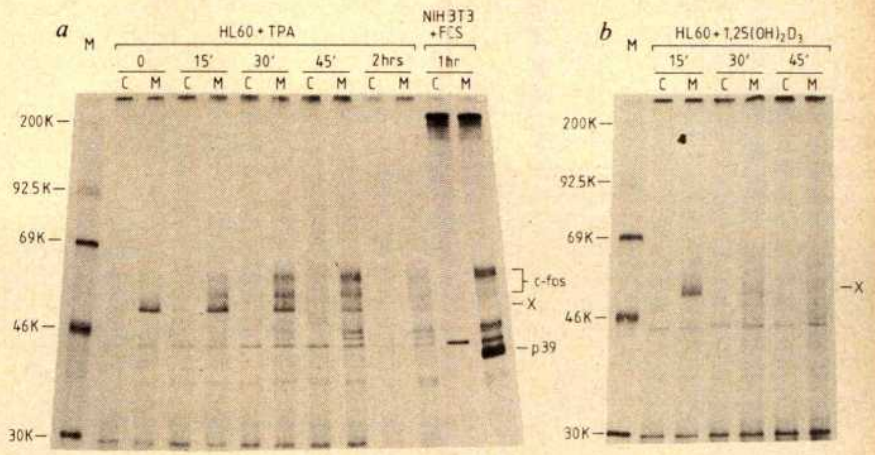

Fig. 2 Immunoprecipitation of c-*fos*-related protein from HL60 cells induced to differentiate by 50×10^{-8} M TPA (*a*) or 10^{-7} M $1,25(OH)_2D_3$ (*b*) for different times. C, Control serum (v-*fos* peptide-specific antiserum; V in ref. 17); M, *fos* peptide-specific antiserum[17]. For comparison, immunoprecipitation of c-*fos* protein from FCS-stimulated NIH 3T3 cells is also shown (*a*). With HL60 cells, immunoprecipitation was performed on lysates of ^{35}S-methionine-labelled cells denatured by boiling for 5 min in 0.5% SDS[17], thus no p39 is co-precipitated in these lanes. The X protein was not found in non-denatured lysates, and its level was subject to considerable experimental variation in denatured cell lysates, suggesting that it may be a cross-reacting protein that shares only very restricted antigenicity with the c-*fos* gene product.

Fig. 2*a*). Protein of very similar M_r was detected in the HL60 cells as early as 15 min after TPA induction. The levels of c-*fos* protein were maximal at 30–45 min, then decreased (Fig. 2*a*). The cellular p39 protein was not detected in this experiment because immunoprecipitation was performed on cell lysates denatured by boiling in SDS. Very similar results were obtained with a *fos*-specific tumour-bearing rat (TBR) serum[19,20] (data not shown). In agreement with RNA analyses, expression of c-*fos* protein was not detectable in $1,25(OH)_2D_3$-induced HL60 cells (Fig. 2*b*). Another group of proteins in the 45 K range increased concomitantly with c-*fos* in both TPA-induced HL60 cells and—as described previously[8]—in fetal calf serum (FCS)-stimulated NIH 3T3 cells. These proteins may be encoded by a c-*fos* related gene, such as r-*fos*, which, in growth factor-stimulated fibroblasts, is co-induced with c-*fos*[10]. Coincidentally, the *fos*-specific antiserum was raised against a peptide that is also contained in the r-*fos* protein[10,17]. A more precise definition of these proteins awaits peptide mapping analyses. Interestingly, a protein of $M_r \sim 55$ K (designated 'X' in Fig. 2) was detectable in denatured lysates of uninduced HL60 cells and disappeared rapidly after induction of differentiation by either TPA or $1,25(OH)_2$-D_3 (Fig. 2*a*,*b*). As c-*fos* RNA is not detectable in uninduced HL60 cells (Fig. 1*a*), the X protein apparently cannot be encoded by c-*fos*. Although this protein was also detected by the *fos*-specific TBR serum (data not shown) its nature remains obscure.

In fibroblasts, c-*fos* expression is rapidly inducible by growth factors and is therefore thought to be associated with growth regulation. Although macrophages are terminally differentiated cells, they still retain the ability to proliferate, unlike most other cell types. Therefore, it was of interest to investigate whether c-*fos* expression in mature macrophages might be correlated with growth. When primary cultures of bone marrow-derived macrophages were deprived of the macrophage-specific growth factor CSF-1 for 18 h (Fig. 3*a*) or kept at low serum concentrations for 24 h (0.5% FCS; data not shown), proliferation ceased and the cells became quiescent. This was accompanied by a marked reduction in levels of both c-*fos* and c-*myc* mRNA (Fig. 3*b*, and data not shown), suggesting that expression of these proto-oncogenes depends on the presence of growth factors (or on cellular proliferation). When CSF-1-deprived macrophages in the G_0 phase of the cell cycle were stimulated by addition of the growth factor, induction of c-*myc* was observed after 1 h, reaching a maximum at 2–4 h. Activation of c-*myc* was followed by an ~10-fold induction of c-*fos* mRNA levels, which remained high for the following 8 h (Fig. 3*b*). Regulation of c-*fos* expression in macrophages differs substantially from that in fibroblasts: (1) in contrast to fibroblasts[8], a high level of c-*fos* expression is evident in normally growing, asynchronous macrophages, and thus appears to be part of the normal cell cycle in these cells; (2) induction of c-*fos* by CSF-1 in macrophages occurs much later than in growth factor-stimulated

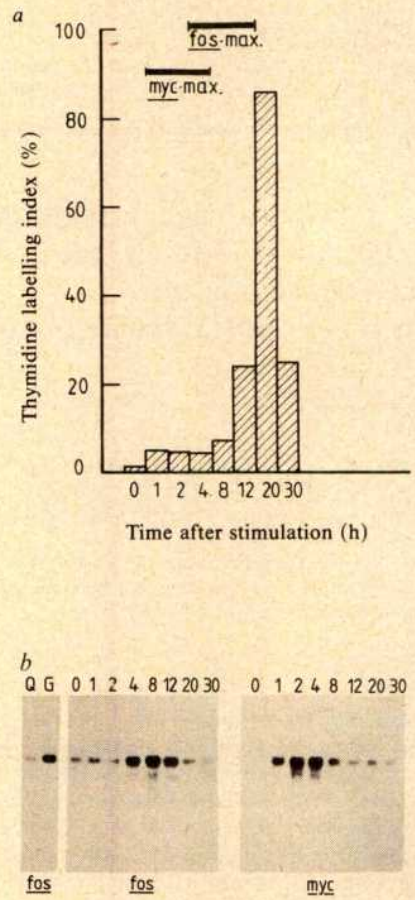

Fig. 3 *a*, Thymidine labelling index at the indicated times after CSF-1 induction of quiescent macrophages. Horizontal bars indicate the periods of maximal c-*fos* and c-*myc* expression, respectively, as observed in the experiment shown in *b*. *b*, Expression of c-*fos* and c-*myc* in quiescent versus growing or stimulated macrophages. Northern blot analysis of RNA from normally growing (G) versus CSF-1-deprived, quiescent (Q) mouse macrophages, and from quiescent macrophages stimulated with CSF-1 for the indicated times (0, 1, 2, 4, 8, 12, 20 and 30 h).

Methods. Primary cultures of bone marrow-derived macrophages from C3H/HeJ mice were established and grown as described previously[13]. Cultures were used at day 7 after establishment. At this time the population consisted of >98% macrophages. Quiescent macrophages were obtained by maintaining the culture for 18 h in CSF-1-free medium supplemented with 15% FCS. Stimulation was carried out by adding 3,000 units of partially purified CSF-1 (stage 1) per ml of medium. Purification of CSF-1 from mouse L-cell supernatant has been described previously[22]. One dish (175 cm^2) of macrophages was used for each time point.

fibroblasts, where it precedes activation of c-*myc*; (3) induction of c-*fos* in macrophages lasts considerably longer than in fibroblasts. While in stimulated fibroblasts c-*fos* induction appears to occur during the transition from the G_0 to G_1 phase of the cell cycle, expression in macrophages is observed during G_1 until mid-S phase. These findings further substantiate our hypothesis[6,8] that the c-*fos* gene product serves different functions in fibroblasts and macrophages.

TPA induces cell proliferation in fibroblasts[21] and differentiation in HL60 cells[12]. In both cases, rapid induction of c-*fos* mRNA and protein was observed (Figs 1, 2; ref. 7 and R. Bravo, J. Burckhardt, T.C. and R.M., unpublished observation). It is possible that the initial biochemical events induced by TPA are the same regardless of whether the ultimate consequence is differentiation or proliferation. Such initial events, in which *fos* may have a role, include the transduction of TPA-induced signals received at the cell membrane within the nucleus. In mature myelomonocytic cells, c-*fos* may be involved in biochemical pathways controlling proliferation and/or securing the survival of macrophages. In this context it is interesting that c-*fos* is induced by the growth factor CSF-1, which has been shown to be required for both growth and survival of macrophages[13].

We thank R. Bravo for valuable discussions, M. R. Uskokovic for $1,25(OH)_2$-D_3, C. Brady for technical assistance, and B. Blanasch for help in preparation of the manuscript.

Increased neurovirulence associated with a single nucleotide change in a noncoding region of the Sabin type 3 poliovaccine genome

D. M. A. Evans*, G. Dunn*, P. D. Minor*, G. C. Schild*, A. J. Cann†, G. Stanway†, J. W. Almond†, K. Currey‡ & J. V. Maizel Jr‡

Most of the small number of cases of poliomyelitis which occur in countries where Sabin's attenuated poliovirus vaccines are used are temporally associated with administration of vaccine and involve polioviruses of types 2 and 3 (ref. 1). Recent studies have provided convincing evidence that the Sabin type 2 and 3 viruses themselves may revert to a neurovirulent phenotype on passage in man[2–6]. We report here that a point mutation in the 5′ noncoding region of the genome of the poliovirus type 3 vaccine consistently reverts to wild type in strains isolated from cases of vaccine-associated poliomyelitis. Virus with this change is rapidly selected on passage through the human gastrointestinal tract. The change is associated with a demonstrable increase in the neurovirulence of the virus.

The complete nucleotide sequences of the genomes of the neurovirulent progenitor of the Sabin type 3 vaccine virus, P3/Leon/37, the Sabin vaccine virus itself, P3/Leon/$12a_1$b, and a virulent revertant strain from the brain of a fatal case of vaccine-associated poliomyelitis, P3/119 (ref. 7), have been determined[4,7–9]. The small number of sequence differences between these strains[4,7] suggested that the following mutations could be involved in attenuation and reversion: (1) a single nucleotide change at position 472 in the 5′ noncoding region of the genome; (2) nucleotide changes resulting in amino-acid changes in the capsid proteins; and (3) a single change at the end of the 3′ noncoding region. Only the nucleotide at position 472 correlated with the neurovirulent phenotype, being cytidine in P3/Leon/37 and P3/119, and uridine in the vaccine strain.

Table 1 Base at position 472, time of isolation, neurovirulence and temperature sensitivity of Sabin type 3 vaccine-derived strains of poliovirus

Virus	Base at position 472	Time of isolation after vaccination	Mean histological lesion score	rct marker test*
Sabin vaccine	U		0.36	>5.5(rct$^-$)
DM1	U	24 h	ND	ND
DM2	U	31 h	1.58	6.13 (rct$^-$)
DM3	U/C	35 h	ND	ND
DM4†	C	47 h	2.48	5.71 (rct$^-$)
DM38	C	18 days	ND	ND
DM119	C	3–4 weeks	3.34	0.25 (rct$^+$)

Mean histological lesion scores were determined using the standard WHO neurovirulence test[14]. The range of mean histological lesion scores of a type III attenuated reference strain in eight tests carried out over the past 2 yr is 0.43–0.79. ND, not determined.

* The rct marker (replicative capacity at temperature −40 °C) test shows the logarithmic difference between virus titres grown at 35 °C and at 40 °C[15]. Viruses showing reductions of log 5.0 or more in titre are considered to be temperature-sensitive (rct$^-$).

† The sequences of the structural coding region and the 5′ noncoding region of DM4 were determined as described previously[10]. The extreme 3′ end of the RNA was sequenced by synthesizing complete complementary DNA copies of the viral RNA, annealing a synthetic oligonucleotide primer to its 5′ end and sequencing by the dideoxy method using the Klenow fragment of *Escherichia coli* DNA polymerase I[13].

We therefore examined the frequency with which the mutation to cytidine at base 472 occurred in viruses from vaccine-associated cases of poliomyelitis, and assessed its effect on the phenotype of the virus.

Twelve strains of poliovirus type 3 from a collaborative study of vaccine-associated poliomyelitis performed by the World Health Organization (WHO)[9] were examined in addition to P3/119. All the strains had been shown to be genetically related to the Sabin vaccine virus by T1 oligonucleotide mapping[2,3,6], and six had been found to be highly neurovirulent[9]. In all 12 strains, the nucleotide at position 472 of the genome was cytidine, as shown by primer extension sequencing[10] using a synthetic primer which annealed to the viral RNA from position 510 to 522 (data not shown). In contrast, the nucleotide at this position in two batches of vaccine was uridine, confirming our previous findings[4,8,9] and those of others[11]. The consistency with which cytidine was detected at position 472 amongst the vaccine-derived revertant viruses suggested that this nucleotide might have an effect on the virulence of the virus.

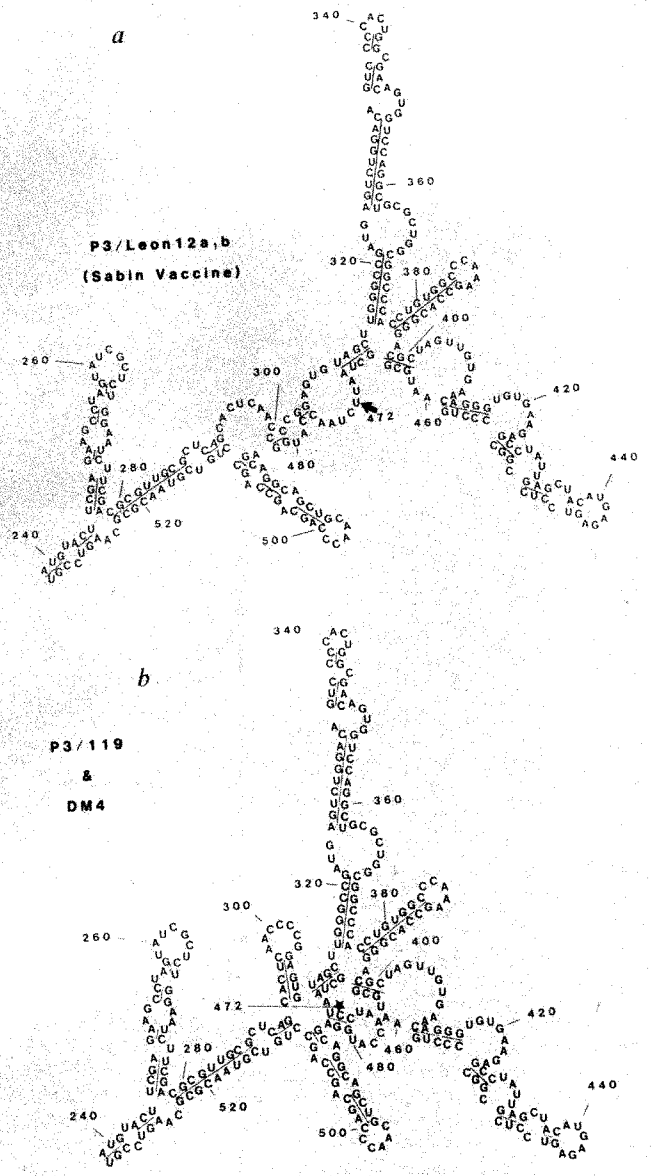

Fig. 1 Predicted secondary structure of RNA (bases 240–540, approximately) from type 3 Sabin poliovirus vaccine strain (*a*) and type 3 revertant strain P3/119 (*b*) based on the improved RNZ folding algorithm of Jacobson *et al.*[18]. We used a recent display algorithm which allows easy visual comparison of similar sequences[19].

It is known that Sabin type 3 vaccine virus increases in neurovirulence on passage in the human gut[12]. Therefore, we attempted to determine whether this loss of attenuation is associated with the substitution at position 472. After oral administration of the trivalent Sabin vaccine to a 4-month-old infant, we collected every faecal sample and attempted to isolate the virus from each. The genomes of several of the successive type 3 isolates were sequenced through position 472 (Table 1). DM1 and DM2, isolates from the first two faecal samples obtained 24 and 31 h after vaccination respectively, possessed U at position 472, as in the vaccine virus. The third isolate, DM3, from a faecal sample collected at 35 h, contained a mixture of viruses with either U or C at position 472. The fourth isolate (DM4), from a sample collected just 47 h after vaccination, and all subsequent isolates sequenced appeared to be homogeneous for C at position 472. These findings suggest strongly that replication of the vaccine virus in the human gut rapidly selects for viruses containing C at position 472 of the genome. No other changes, including those with significance for reversion[4,13], were detected when the entire structural coding region and the 3′ and 5′ noncoding regions of DM4 were sequenced (Table 1).

To assess the significance of the mutation at position 472 for neurovirulence, DM2 and DM4 were assayed in a standard WHO neurovirulence test[14]. DM4 was found to be significantly more neurovirulent than the vaccine strain with respect to both the histological lesions in the central nervous system (CNS) (Table 1) and the paralysis induced (data not shown), although it was not as neurovirulent as the revertant P3/119 (Table 1). The second isolate, DM2, had a higher lesion score than the Sabin vaccine strain. Our interpretation of this finding is that DM2 probably contained a small proportion of virus with C at position 472 which was undetectable by the sequencing methods used.

DM4 was found to be temperature-sensitive (rct$^-$) (Table 1), as is the Sabin vaccine virus[15]. In contrast, the revertant P3/119 was rct$^+$, as were all other revertants tested[9]. Therefore, it seems that reversion at position 472 alone does not account for the rct$^+$ phenotype of revertant strains.

As the extremely rapid selection of virus having cytidine at position 472 could be atypical, daily faecal samples were collected from three other vaccinated infants; 4 days after vaccination all three subjects were excreting virus having C at position 472 (Table 2).

Table 2 Base at position 472 of the poliovirus genome in primary vaccinees

Day post-vaccination	Vaccinee KT1	KT2	KT3
1	U	*	U
2	U/C	*	U
3	C	*	C
4	C	C	C

Faecal samples were taken daily from three vaccinated infants less than 1 yr old, who received vaccine of the same origin as DM (Table 1).
* Isolates of poliovirus type 3 not available.

Virus with C at position 472 is thus selected for rapidly and consistently following administration of vaccine, the short period of time before the appearance of the first isolate with C probably representing only a few cycles of virus replication.

The basis of the selective advantage conferred by the presence of C at position 472 and the function of the 5′ noncoding region are unclear. The degree of sequence homology between the three poliovirus serotypes in the 5′ noncoding region is high (74%)[16]. Moreover, this is the region that is most conserved between the genomes of polioviruses and rhinovirus type 14 (ref. 17). This strong conservation suggests that the region has functional significance. One possibility is that some of the short open reading frames present in this region are functional and that their products remain undetected. Other possible functions of this 5′ region include replicase binding on the negative-strand RNA, packaging of RNA into new virus capsids, uncoating and control of the initiation of translation. Such functions could conceivably depend on RNA secondary structure.

Figure 1 shows a prediction of the secondary structure of the RNA[18,19] of the Sabin vaccine virus and of isolate P3/119; the change from U to C at position 472 in P3/119 causes a substantial rearrangement, so that two additional stem-and-loop structures are formed. A similar structure to that shown for P3/119 was also predicted for the virulent vaccine progenitor P3/Leon/37.

We have shown that for poliovirus type 3, a single nucleotide change of U to C at position 472 in the noncoding region of the viral genome provides a selective advantage for growth in the human gut. This change is associated with an increase in neurovirulence of the virus although it does not, on its own, give rise to a fully neurovirulent phenotype. Neither the nature of the selective environment nor the basis of the selective advantage conferred by the change is known.

It is of interest that, according to the particular RNA folding algorithm used in the present study, the U to C mutation appears to have a profound effect on the predicted secondary structure

of the virus RNA, but it remains to be established whether the secondary structures presented and the differences between them have any biological significance. It is possible that analogous changes are important in the attenuation of poliovirus types 1. The type 1 vaccine strain, P1/LSc, shows seven differences compared with its neurovirulent parent, P1/Mahoney, in the noncoding region of its genome[16], and consequently some major rearrangements in the secondary structure of the RNA were predicted by this particular algorithm, including some in the region of position 472.

We thank Dr Clayton Naeve, St Jude's Children's Hospital, Memphis, Tennessee, for the synthesis of several oligonucleotide primers used in this study. We also thank Dr Frank Taffs, Dr Christine Miller, Susan Marsden, Anne John, Susan Fraser and David Minor for their contributions.

Suppression of leukaemia virus pathogenicity by polyoma virus enhancers

Brian Davis*, Elwood Linney† & Hung Fan*

* Department of Molecular Biology and Biochemistry, University of California, Irvine, California 92717, USA
† Department of Microbiology, Duke University School of Medicine, Durham, North Carolina 27706, USA

The long terminal repeats (LTRs) of retroviruses contain sequences necessary for the initiation and termination of retroviral transcription. These sequences include promoter elements, transcriptional termination signals and transcriptional enhancer elements. The enhancer elements of Moloney murine leukaemia virus (M-MuLV) are localized in a tandemly repeated region (~75 base pairs (bp) long), which lies 5′ to the CAT and TATA promoter elements in the U3 region of the LTR (see Fig. 1)[1]. We have shown that the tandem repeats are required both for LTR promoter activity, as measured by transient expression assays, and for biological activity, as measured by production of infectious virus[2]. Furthermore, they can be replaced by transcriptional enhancers from the F101 host-range mutant of polyoma virus without loss of function. We report here that the addition of the polyoma (PyF101) enhancers to the M-MuLV LTRs (either with or without the M-MuLV tandem repeats) results in complete loss of viral leukaemogenicity, even though the virus can replicate to high titres in tissue culture fibroblasts and can establish infection in animals.

Figure 1*A* shows the modified M-MuLV LTRs used in the present study. Mo+PyF101 was constructed by inserting the PyF101 enhancer element into the wild-type M-MuLV LTR at

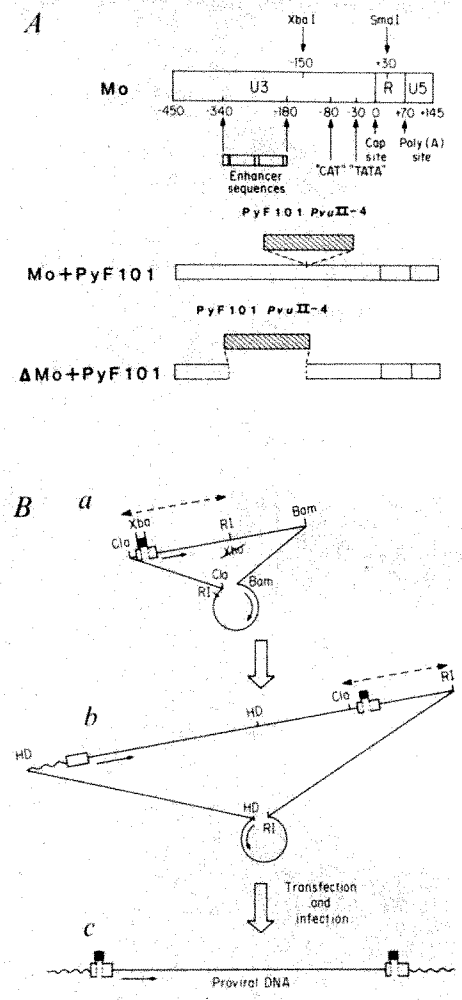

Fig. 1 *A*, M-MuLV LTRs used for tests of infectivity and pathogenicity. Mo, The wild-type M-MuLV LTR from a clone of circularly permuted proviral DNA, pMLV-1a[1,24]; the sequences important in proviral transcription are indicated. The tandem repeats, implicated as enhancer elements[14,25], are located upstream (−341 to −182) of the promoter region. Mo+PyF101, LTR containing the *Pvu*II-4 fragment of mutant polyoma virus PyF101 (ref. 26) inserted into the M-MuLV LTR at the *Xba*I site at position −150, 30 bp 3′ of the M-MuLV tandem repeats. Mo+PyF101 was constructed by first adding *Xba*I linkers to the 199-bp *Pvu*II-4 fragment[2], then inserting it into M-MuLV at the *Xba*I site. ΔMo+PyF101, LTR containing the PyF101 *Pvu*II-4 fragment inserted into an M-MuLV LTR in which the tandem repeats (−335 to −150) have been deleted (see ref. 2 for details of construction). The orientation of the PyF101 *Pvu*II-4 fragment relative to the Moloney promoter is identical in ΔMo+PyF101 and Mo+PyF101. ***B***, The strategy used to construct M-MuLVs with modifications in the U3 region of the LTR. The *Cla*I to *Eco*RI fragment of ΔpMLV-C/R/B+PyF101 (*a*) was used to construct a complete M-MuLV recombinant DNA provirus containing a 3′ ΔMo+PyF101 LTR (*b*) (see ref. 2 for details). The construct containing the Mo+PyF101 LTR was produced in a similar fashion. As the LTR alterations were all located within the U3 region, transfection of these constructs and subsequent infection of neighbouring cells would result in proviruses containing modified LTRs at both their 5′ and 3′ ends (*c*).

−150 bp, between the M-MuLV tandem repeats and the M-MuLV promoter. ΔMo+PyF101 comprises an insertion of the PyF101 enhancer into an M-MuLV LTR from which the M-MuLV enhancer elements (from −335 to −150 bp with respect to the RNA cap site) have been deleted[2]. The biological activity of the LTRs was assessed by constructing a plasmid containing the complete M-MuLV proviral DNA sequence, with the altered LTR replacing the 3′ LTR, transfecting this plasmid into NIH 3T3 cells and assaying for infectious virus[2] (see Fig. 1*B* for a

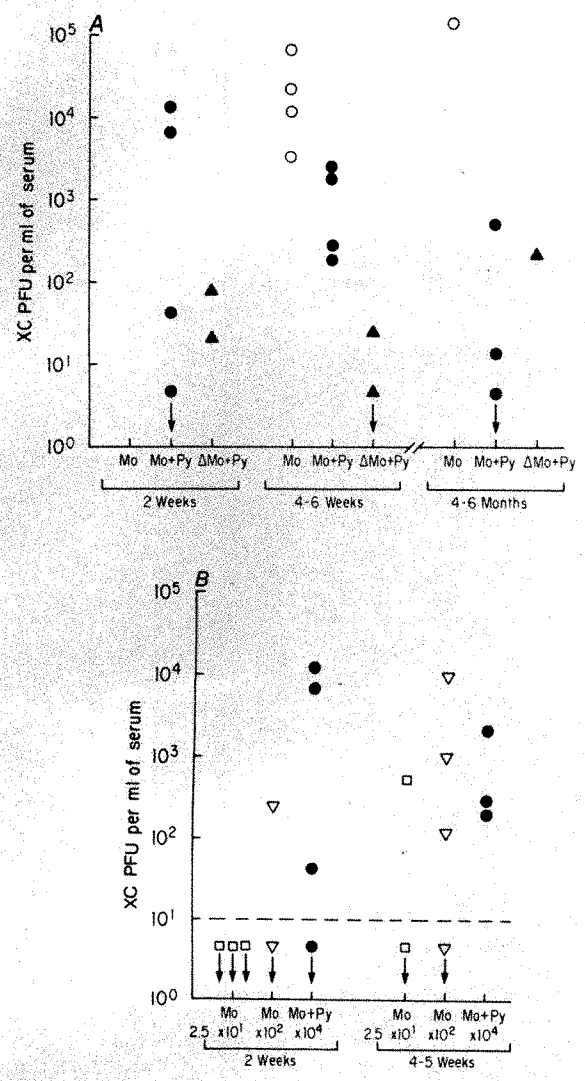

Fig. 2 Levels of circulating infectious virus in inoculated animals. Serum samples from mice injected i.p. 1–5 days after birth with either wild-type or polyoma-containing M-MuLVs were assayed by infection and titration on NIH 3T3 cells using the UV-XC assay[22]. Each data point in *A* and *B* shows the titration results obtained for a different sacrificed animal. Data points with downward-pointing arrows represent animals having virus levels undetectable in this assay ($<10^1$ XC PFU per ml of serum). *A*, Levels of virus in animals inoculated with 2.5×10^4 XC PFU of wild-type (○), Mo+PyF101 (●) or ΔMo+PyF101 (▲) M-MuLVs. Titration results are given for animals at 2 weeks, 4–6 weeks, and 4–6 months after injection. *B*, Levels of virus in animals inoculated with 2.5×10^1 XC PFU of wild-type M-MuLV (□), 2.5×10^2 XC PFU of wild-type M-MuLV (▽), or 2.5×10^4 XC PFU of Mo+PyF101 M-MuLV (●). Results are shown for animals 2 weeks and 4–5 weeks post-injection.

brief outline of these procedures). Infectious virus containing either of the altered LTRs could be recovered (designated Mo+PyF101 M-MuLV and ΔMo+PyF101 M-MuLV). Note that the alterations in these viruses lie in regions that do not encode protein, thus the virus particles are identical to wild-type M-MuLV.

To assess the relative infectivities of the ΔMo+PyF101 and Mo+PyF101 viruses, virus produced by the transfected cultures was infected onto NIH 3T3 cells, which were then transferred until confluently infected. The amount of infectious virus produced by the cultures was assayed by titration of tissue culture supernatants on NIH 3T3 cells (Table 1). Cells infected with the two PyF101-containing viruses produced high amounts of infectious virus, although less than the amount produced by wild-type M-MuLV. As quantified by the reverse transcriptase

Table 1 Biological activity of M-MuLV containing altered LTRs

LTR	Titre of infectious virus	No. of virus particles (reverse transcriptase assay)	Infectivity-to-particle ratio
Mo	1.1×10^7	4.4×10^6	2.5
Mo+PyF101	1.6×10^6	3.0×10^6	0.53
ΔMo+PyF101	5.0×10^5	3.1×10^6	0.16

Virus released from NIH 3T3 cells transfected with the M-MuLV proviral constructs containing altered LTRs was infected onto fresh NIH 3T3 cells. The freshly infected cells were transferred four times, after which all cells were infected; 24-h tissue culture supernatants were collected from 10^6 cells and assayed for concentration of infectious virus and for the number of virus particles present. The titre of infectious virus was quantified by titration of supernatants onto NIH 3T3 cells using the rat XC cell syncitial assay[22]; the values shown represent XC PFU ml^{-1}. The number of virus particles present was determined by the reverse transcriptase assay, using poly(rA)/oligo(dT) as exogenously added template/primer[25]; the values shown represent c.p.m. dTTP incorporated in a 75-min reaction for virus collected from 1 ml of tissue culture supernatant. Typical values for dTTP incorporation ranged from 4.0×10^5 to 6.5×10^5 c.p.m.; supernatant from uninfected NIH 3T3 cells yielded approximately 1% as much dTTP incorporation. Infectivity-to-particle ratios were calculated by dividing the infectious virus titre by the reverse transcriptase activity for each of the infected cell tissue culture supernatants.

assay (Table 1), cells infected with ΔMo+PyF101 and Mo+PyF101 M-MuLVs produced almost the same number of virus particles as wild-type M-MuLV. To compare directly the infectivity of the polyoma-containing MuLVs with that of wild-type M-MuLV, infectivity-to-particle ratios were calculated by dividing the infectious virus titre by the reverse transcriptase activity present in each of the infected tissue culture supernatants (Table 1). Compared with wild-type M-MuLV, Mo+PyF101 virus showed a slight (fivefold) decrease in specific infectivity and ΔMo+PyF101 virus a somewhat greater (15–30-fold) decrease. Thus, the polyoma-containing M-MuLVs are able to productively infect NIH 3T3 fibroblasts, and show only slightly decreased infectivity compared with wild-type M-MuLV.

The pathogenicity of wild-type, ΔMo+PyF101 and Mo+PyF101 M-MuLVs was assessed by inoculating neonatal (1–3-day-old) NIH Swiss mice intraperitoneally (i.p.) with equal infectious units ($\sim2.5\times10^4$ XC plaque-forming units, PFU) of each virus, then monitoring the mice for appearance of disease; any moribund animals were autopsied. Injection of six neonates with wild-type M-MuLV resulted in development of typical M-MuLV thymic leukaemia and death in all of the animals. Diseased animals showed enlarged thymuses, spleens or lymph nodes. The mean time until the disease became apparent was 3 months, with all mice developing the disease before 4 months. These results are in agreement with those obtained by us and others for M-MuLV[3]. In contrast, there was no evidence of disease in 10 neonates (from two litters) injected with Mo+PyF101 M-MuLV and in 17 neonates (from two litters) injected with ΔMo+PyF101 M-MuLV, even 12–13 months after injection. Also, autopsies of animals inoculated with either virus showed no signs of abnormality or malignancy. These results suggest that Mo+PyF101 and ΔMo+PyF101 M-MuLVs are non-leukaemogenic, even when inoculated at high titre.

One possible explanation for the lack of pathogenicity of the altered viruses is that they are unable to establish infection *in vivo*, even though they can replicate in tissue culture. To examine this possibility, circulating levels of infectious virus in inoculated animals were measured by titration of the blood serum on NIH 3T3 cells (Fig. 2*A*). Infectious XC-positive MuLV was recovered from the great majority of mice (13 out of 16) inoculated with Mo+PyF101 M-MuLV or ΔMo+PyF101 M-MuLV, at time points between 2 weeks and 6 months after injection. XC-positive virus (although at low titre) was recovered even 5–6

months after injection with the polyoma-containing M-MuLVs, which further emphasizes that these viruses were able to establish and sustain multiple rounds of infection in the inoculated neonates. The low titres of virus present at later time points in Mo+PyF101 M-MuLV-injected animals (compared with animals inoculated with wild-type M-MuLV) may have resulted from an immune response in the absence of any malignant growth of infected thymoma cells.

Even though the polyoma-containing viruses were clearly able to establish infection *in vivo*, it was conceivable that the lack of leukaemogenicity might have resulted from a quantitative defect in the level of infection established. Multiple rounds of infection in the animal are probably necessary for leukaemogenesis by M-MuLV, shown by the eventual appearance of 'mink cell focus-inducing' recombinant MuLVs[3,4], and by the site specificity of proviral integration in tumour cells[5-8]. To investigate this possible defect in more detail, neonatal mice were inoculated with lower levels of wild-type M-MuLV which were still sufficient to induce leukaemia (2.5×10^1 and 2.5×10^2 XC PFU per animal) and the circulating levels of M-MuLV were compared with those in animals inoculated with concentrated Mo+PyF101 M-MuLV (Fig. 2*B*). At 2 weeks post-injection, the levels of viraemia in animals inoculated with the diluted stocks of wild-type M-MuLV were significantly lower (undetectable in several animals) than in animals inoculated with concentrated Mo+PyF101 M-MuLV. Even at 4–5 weeks after injection, the increased levels of viraemia in animals inoculated with wild-type M-MuLV were only equivalent to those in animals inoculated with Mo+PyF101 M-MuLV. Thus, the level of infection in the Mo+PyF101 M-MuLV-inoculated animals would have been more than sufficient to cause disease if the virus had been wild-type. Animals inoculated with ΔMo+PyF101 M-MuLV also showed equivalent or higher levels of viraemia at 2 weeks post-inoculation than the animals inoculated with the diluted M-MuLV stocks.

The virus recovered from a 5-month animal inoculated with Mo+PyF101 M-MuLV was further characterized, since it was possible that recombination within the animal might have given rise to virus different from the input Mo+PyF101 M-MuLV. RNA and high relative molecular mass DNA were extracted from NIH 3T3 cells uniformly infected with the recovered virus and analysed by RNA dot-blot and DNA Southern blot analysis, respectively (Fig. 3*A*, *B*). RNA from the infected cells hybridized with a nick-translated PyF101 probe, confirming that M-MuLV containing the Mo+PyF101 LTR was still present in the animal 5 months after injection (Fig. 3*A*). DNA from cells infected with the recovered virus was digested with *Pvu*II and Southern blot hybridization was performed using an M-MuLV probe which detects a 1.88-kilobase (kb) fragment extending from −0.45 kb (relative to the cap site) in the Mo+PyF101 LTR to a *Pvu*II site at 1.43 kb on the proviral map (Fig. 3*C*). This *Pvu*II fragment is 199 bp larger in the Mo+PyF101 provirus than the equivalent fragment from wild-type M-MuLV provirus (1.68 kb) as a result of the insertion of the PyF101 sequences. Figure 3*B* shows that the *Pvu*II fragment in cells infected with the recovered virus was the same size as that in cells infected with the original Mo+PyF101 M-MuLV. Furthermore, no *Pvu*II fragments of different size were observed, indicating that no new M-MuLVs with recombinant LTRs arose in the animals inoculated with Mo+PyF101 M-MuLV.

These results suggest that the presence of polyoma virus enhancer sequences in the M-MuLV LTR abolishes the leukaemogenicity of the virus, even though it is still able to replicate in tissue culture fibroblasts and in the animal. The loss of pathogenicity did not result from an inability to establish infection in the animal, suggesting rather that it may reflect a change in tissue tropism of the virus resulting from addition of the polyoma enhancer sequences. The loss of leukaemogenicity may be a result of the polyoma-containing viruses being less able to infect the target cell(s) involved in development of M-MuLV lymphoma. There is accumulating evidence that certain transcriptional regulatory elements, including enhancers,

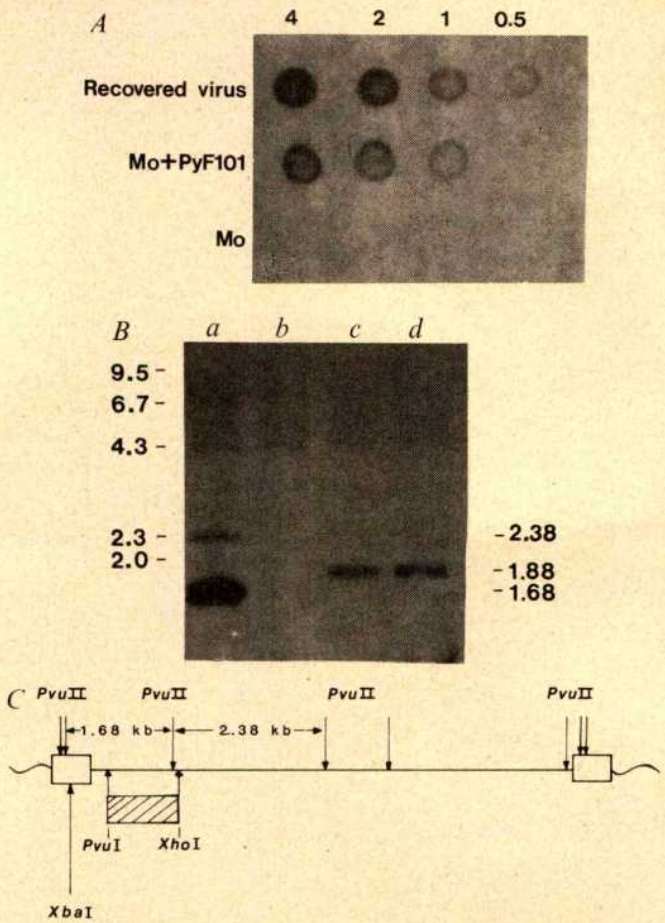

Fig. 3 Characterization of virus recovered from an animal inoculated with Mo+PyF101 M-MuLV. ***A***, RNA dot-blot hybridization[27] of total cytoplasmic RNA[28] isolated from NIH 3T3 cells confluently infected with wild-type M-MuLV (Mo), Mo+PyF101 M-MuLV, or virus recovered from the bloodstream of a mouse 5 months after inoculation with Mo+PyF101 M-MuLV (recovered virus). The amounts of RNA spotted onto the nitrocellulose sheet[27] were as shown (4, 2, 1 and 0.5 μg). The sheet was hybridized with ^{32}P-labelled nick-translated PyF101 *Pvu*II-4 fragment, and subjected to autoradiography. The probe hybridized with RNA from cells infected with Mo+PyF101 and with recovered virus, but not with RNA from cells infected with wild-type M-MuLV. RNA from all three cell lines hybridized with a labelled nick-translated M-MuLV probe (data not shown). ***B***, Southern blot hybridization of *Pvu*II-digested genomic DNA of high relative molecular mass, isolated from NIH 3T3 cell lines infected with wild-type M-MuLV (*a*), Mo+PyF101 M-MuLV (*d*) or recovered virus (*c*), and from uninfected NIH 3T3 cells (*b*). The Moloney cell line used in this experiment, M-MuLV clone A9, has been described previously[23]. Isolation of genomic DNA and blot-transfer hybridization were performed as described elsewhere[29,30]. The hybridization probe was a 1.1-kb *Pvu*I to *Xho*I fragment from 0.42 to 1.55 kb, relative to the cap site, on the proviral map (*C*). Hybridization with *Pvu*II-digested M-MuLV clone A9 DNA revealed two fragments of 1.68 and 2.38 kb (*a*), which were not present in *Pvu*II-digested uninfected NIH 3T3 DNA (*b*). The weakly hybridizing fragments (~4–9 kb) present in both uninfected and infected NIH 3T3 cells represented endogenous M-MuLV proviral sequences present in uninfected mouse cells. Insertion of the 199-bp PyF101 *Pvu*II-4 fragment in the Mo+PyF101 LTR increased the size of the 1.68-kb M-MuLV fragment to 1.88 kb, as predicted (*d*). The 2.38-kb M-MuLV fragment, although difficult to identify in *d*, was recognizable in the original autoradiogram. The weak hybridization to the 2.38-kb fragment was expected, as only a small fraction of the nick-translated M-MuLV *Pvu*I to *Xho*I restriction fragment could hybridize with the 2.38-kb *Pvu*II fragment (see *C*). The hybridization pattern obtained for cells infected with the recovered virus (*c*) was indistinguishable from that of Mo+PyF101 M-MuLV-infected cells (*d*). ***C***, The *Pvu*II restriction map of an integrated wild-type M-MuLV provirus, and the relative position of the nick-translated *Pvu*I to *Xho*I probe (hatched bar). The *Xba*I site in the LTR is also indicated.

can confer tissue specificity of expression[2,9-14]; in fact, recent reports suggest that enhancer sequences in the LTR determine the thymotropism and pathogenicity of murine leukaemia viruses[15-21].

We have found that loss of leukaemogenicity occurs not only for an M-MuLV LTR in which the M-MuLV tandem repeats have been replaced by the PyF101 enhancer (ΔMo+PyF101), but also for an M-MuLV LTR in which PyF101 enhancers have been added to a wild-type LTR still containing the M-MuLV enhancers (Mo+PyF101). The behaviour of Mo+PyF101 M-MuLV suggests that the PyF101 enhancer sequences exerted a dominant effect over the M-MuLV enhancer sequences present in the Mo+PyF101 LTR.

Expression of enhanced levels of small RNA polymerase III transcripts encoded by the *B2* repeats in simian virus 40-transformed mouse cells

Karambir Singh, Michael Carey, Sentob Saragosti & Michael Botchan

Department of Molecular Biology, University of California, Berkeley, California 94720, USA

Although specific viral genes are known which are sufficient to transform certain types of cells, viral transformation has been shown to be accompanied by a change in the level of expression of cellular genes. Assuming that this latter class of genes is involved in some way in the establishment of the transformed state, we and others[1,2] have sought to characterize them. To this end, we constructed a complementary DNA library from a simian virus 40 (SV40)-transformed mouse cell line and screened this library for induced genes. Here we focus on the characterization of a specific cDNA clone called 10λ5. We show that the clone 10λ5 contains a *B2* repeat[3,4], and that the levels of the small heterogeneously sized *B2* cytoplasmic RNAs homologous to 10λ5 are enhanced in transformed cells. Our studies show that these RNAs are a specific class of polymerase III transcripts containing a highly conserved 5′ end. SV40 transformation results, therefore, in the activation of specific polymerase III transcripts as well as specific polymerase II transcripts.

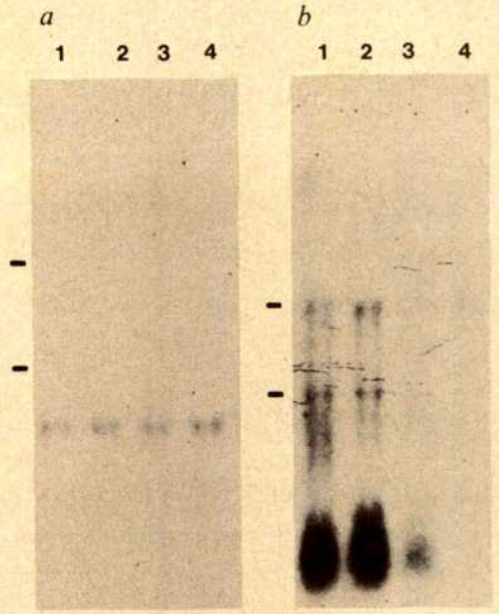

Fig. 1 Northern blot analysis of transcripts with homology to 8λ2, a non-differentially expressed cDNA clone that serves as a control (*a*), and 10λ5 (*b*). The lanes contain RNA from cells grown to different densities. Each lane contains 20 μg of cytoplasmic RNA. The lanes are: 1, SVLTR-1[22], cell density per 90 cm plate = 2.3×10^6; 2, SVLTR-1, cell density 18×10^6; 3, NIH 3T3, cell density, 2.7×10^6; 4, NIH 3T3, cell density, 5.5×10^6. Lanes 1 and 3 represent non-confluent cells and lanes 2 and 4 represent confluent cells. The positions of the 28S and 18S rRNAs are represented by lines on the left of each panel. In overexposed autoradiograms of total cytoplasmic RNA, some hybridization to both 18S and 28S RNA is detectable. The levels of the small RNAs homologous to 10λ5 shown in *b* are about fivefold greater in the transformed cell than in the non-confluent parental cell and about 20-fold greater in the transformed cell than in the confluent parental cell.

Methods. To isolate cDNA clones representing differentially expressed genes such as 10λ5, a plus/minus screen was performed on ≈10,000 phage from the SVLTR-1 λgt10 cDNA library. The cDNA probes used in the screening represented the poly(A)$^+$ RNA of either the NIH 3T3 or SVLTR-1 cells. Those cDNAs that consistently revealed a differential expression were isolated, subcloned into pBR322 and used as probes of Northern blots. Cells were grown in Dulbecco's modified minimal essential medium (DMEM) containing 10% calf serum. For the isolation of cytoplasmic RNA, $\approx10^8$ cells were washed with phosphate-buffered saline, and then lysed by resuspending the cells in 1 ml of 0.5 M NaCl, 10 mM Tris (*p*H 7.5), 1.5 mM $MgCl_2$, 0.65% NP40. After incubation at 0 °C for 10 min, an equal volume of 7 M urea, 0.35 M NaCl, 10 mM Tris (*p*H 7.5), 10 mM EDTA, 1% SDS was added to the supernatant. This was extracted twice with phenol/chloroform/isoamyl alcohol (50:48:2) containing 0.1% 8-hydroxyquinoline, extracted twice with chloroform/isoamyl alcohol (24:1) and ethanol precipitated. For Northern blot analysis, 20 μg of cytoplasmic RNA was dissolved in sample buffer containing 1×running buffer (RB, 20 mM MOPS (*p*H 7.0), 1 mM EDTA, 5 mM NaAc), 50% (v/v) formamide, and 2.2 M formaldehyde. The RNA was then heated for 5 min at 65 °C and electrophoresed in 1–1.5% agarose gels containing 1×RB and 2.2 M formaldehyde. The position of the ribosomal RNA was visualized by acridine orange staining and the RNA was transferred to nitrocellulose paper in 20×SSC. The filters were air dried and baked for 2 h *in vacuo* at 80 °C. Hybridization conditions were as described elsewhere[23,24]. Plasmid probes used were labelled by nick-translation to a specific activity of $1\text{–}2\times10^8$ c.p.m. per μg.

Figure 1 is a Northern blot showing that the small RNAs homologous to 10λ5 are more abundant in the SV40-transformed cell line than in the parental NIH 3T3 cell line. The

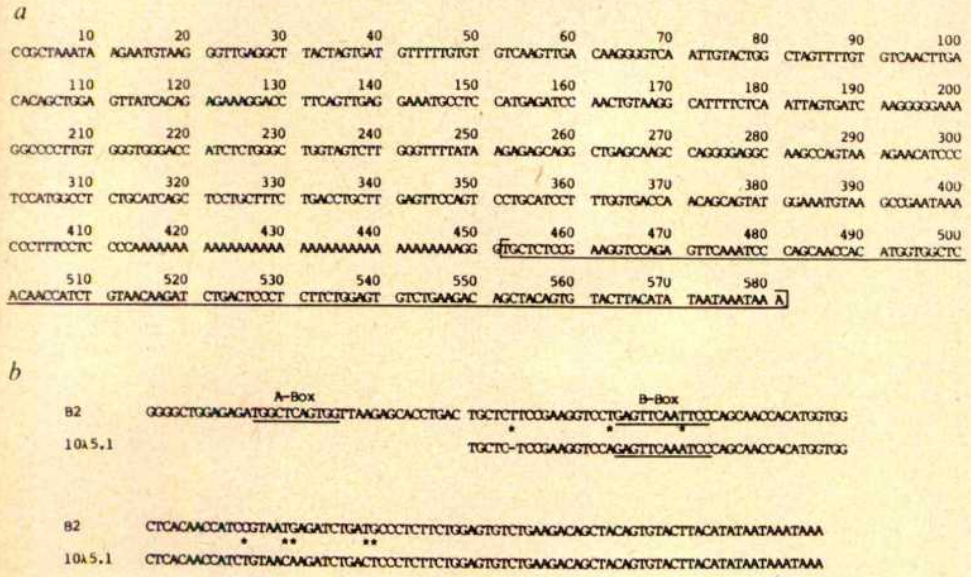

Fig. 2 *a*, The nucleotide sequence of 10λ5 determined by the chemical degradation procedure of Maxam and Gilbert[25]. The *B2* repeat sequences are underlined. The upstream sequence shows no extensive homology to any known sequence. *b*, Comparison of the sequence of the *B2* repeat in 10λ5 with the rodent *B2* consensus sequence[4]. Asterisks represent differences between the 10λ5 repeat and the *B2* consensus sequence. The sequences representing the A and the B boxes of the split polymerase III promoter[15] are underlined. The 10λ5 *B2* sequence lacks both the first 39 nucleotides at the 5′ end of the repeat, including the putative A box of the split polymerase III promoter, and 15–20 bp from the heterogeneous, A-rich 3′ end. However, over the remaining 131 bp, our sequence differs by only 6% from the consensus sequence.

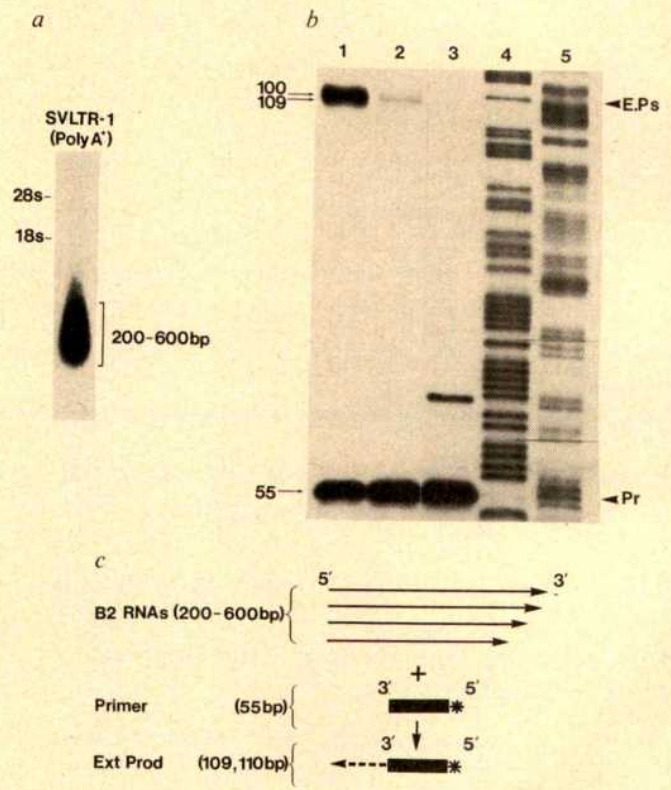

Fig. 3 *a*, Northern blot analysis of *B2* transcripts homologous to 10λ5 in 1 μg of poly(A)$^+$, cytoplasmic SVLTR-1 RNA. *b*, Primer extension analysis of SVLTR-1 cytoplasmic RNA using a *B2* gene specific probe. 1 μg (lane 1) and 100 ng (lane 2) of RNA were subjected to primer extension as described in *c*. Lane 3 is a mock reaction with no RNA. The extension products were sized alongside a sequencing ladder of known sequence. The *Bam*HI/*Hin*dIII fragment of the plasmid pXbs-73x201 (a *Xenopus borealis* 5S clone) was labelled at the *Bam* site using polynucleotide kinase and [γ^{32}P]ATP. The fragment was then subjected to Maxam–Gilbert sequencing reactions[25] for purines (lane 4) and pyrimidines (lane 5). The band which migrated just above the primer in lane 3 is double-stranded primer which remained undenatured. Pr denotes primer and E.Ps denotes extension products. *c*, A schematic illustration of the *B2* primer extension procedure. The 55-nucleotide *Bgl*II/*Ava*II coding strand fragment of 10λ5 (Fig. 2*a*, nucleotides 467–521), 5′ labelled at the *Bgl*II site, was prepared by standard procedures. This fragment was hybridized to total SVLTR-1 cytoplasmic RNA. The hybridized primer was then extended to the 5′ end of the RNA by reverse transcriptase and deoxynucleotide triphosphates (dNTPs) to generate two major extension products of 109 and 110 nucleotides. More than 80% of the extension products are associated with this doublet. The 3′ heterogeneity of *B2* RNAs is illustrated by the different-sized arrows.

Methods. Primer extension reactions were performed as described by McKnight *et al.*[26] with minor modifications. RNA samples were mixed with 5×10^4 c.p.m. (0.01–0.05 pmol) of single-stranded labelled DNA primer in 300 mM NaCl, 10 mM Tris *p*H 7.5 and 1 mM EDTA. The mixture was heated at 85 °C for 10 min, then annealed at 55 °C for 2.5 to 3.0 h. Following the hybridization, samples were incubated with 100 U ml^{-1} of avian myeloblastosis virus reverse transcriptase in a buffer containing 60 mM NaCl, 10 mM Tris *p*H 7.5, 10 mM dithiothreitol (DTT), 1 mM dNTPs, 8 mM $MgCl_2$, 50 μg ml^{-1} actinomycin D and 1,000 U ml^{-1} RNAsin. These reactions were incubated at 42 °C for 1 h and terminated by phenol extraction. The reactions were ethanol precipitated and resuspended in 90% formamide dye mix, heated at 90° for 3 min and loaded onto 8% polyacrylamide sequencing gels. Gels were autoradiographed for 12 h with a Cronex intensifying screen.

augmentation ranges over 5–20-fold depending on the growth state of the parental cells. These small RNAs are also detected by 10λ5 in Northern blots of poly(A)$^+$-selected RNAs (Fig. 3*a*). We find that these small RNAs are augmented in three other SV40-transformed mouse NIH 3T3 cell lines and in bovine papilloma virus- and methylcholanthrene-transformed cell lines (data not shown). Southern[5] hybridization analysis of genomic DNA from various mouse cell lines using 10λ5 as a probe always showed an intense smear pattern, indicating that 10λ5 contains a highly repetitive element.

The nucleotide sequence of 10λ5 is shown in Fig. 2*a*. The cDNA is 581 base pairs (bp) long, and at one end there is an incomplete copy of a member of the highly repetitive mouse *B2* family[3,4]. Family members are about 190 bp in size and are highly conserved in all rodent species. *B2* RNAs were initially observed to be present at higher levels in both Ehrlich carcinoma and MOPC cells than in mouse liver cells[6]. The reports of Scott *et al.*[1] and ourselves have now added significance to this initial observation by independently showing that these small RNAs are induced in various transformed mouse cells.

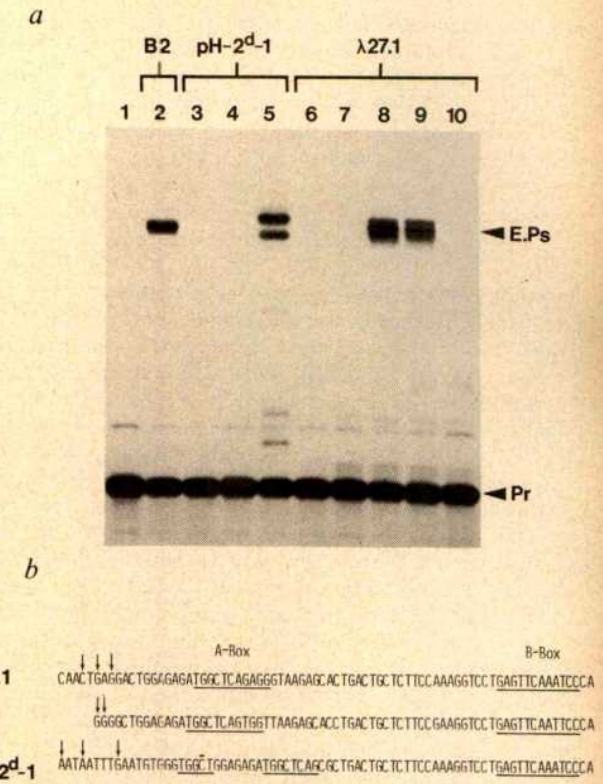

Fig. 4 *a*, Primer extension analysis of RNA transcribed *in vitro* with partially purified HeLa cell transcription factors and cloned DNAs containing *B2* elements. The two clones studied were pH-2^d-1 and λ27.1. The plasmid pH-2^d-1 contains a *B2* element in the 3′-untranslated region of the *H-2D* mouse class I gene of the major histocompatibility complex (MHC)[8] and the λ clone λ27.1 contains a mouse class I MHC pseudogene which has a *B2* element in the third intron[7]. Lane 1, a mock reaction with the primer alone; lane 2, the extension products for 500 ng of SVLTR-1 RNA; lanes 3–5, the extension products of RNAs generated by incubating pH-2^d-1 with polymerase III and TF-B (lane 3), polymerase III and TF-C (lane 4) and polymerase III, TF-B and TF-C (lane 5); lanes 6–10, the extension products of RNAs produced by incubating λ27.1 with polymerase III and TF-B (lane 6), polymerase III and TF-C (lane 7) polymerase III, TF-B and TF-C (lane 8), polymerase III, TF-B, TF-C and 2 μg ml^{-1} of α-amanitin (lane 9) and polymerase III, TF-B, TF-C and 200 μg ml^{-1} of α-amanitin (lane 10). It is not clear why the *in vivo* pattern is more homogeneous than the *in vitro* patterns. Longer exposures of this autoradiogram show that the *in vivo* starts as seen in lane 2 contain other minor bands within 2–3 bp both 5′ and 3′ to the starts shown. Pr denotes primer and E.Ps denotes extension products. *b*, A sequence comparison of the *B2* elements transcribed *in vitro* with the *B2* consensus sequence. Both pH-2^d-1 and 27.1 are aligned with the *B2* consensus sequence by their B box homologies. The A and B box sequence homologies are underlined and the *in vitro* and *in vivo* initiation sites are denoted by arrows.

Methods. A HeLa cell S100 extract was prepared as described by Weil *et al.*[27]. The transcription factor (TF) assays and the first step of the purification were modifications of those described by Segall *et al.*[16]. The extract was loaded onto a phosphocellulose column (P11 Whatman) pre-equilibrated in buffer A (20 mM HEPES *p*H 7.5, 20% glycerol, 0.2 mM EDTA and 0.5 mM DTT) and 100 mM KCl. TF-B activity was eluted with buffer A and a linear salt gradient of 100–350 mM KCl. Active fractions were pooled and dialysed for 8 h against buffer A and 50 mM KCl. The dialysate was loaded onto a DEAE-cellulose (DE-52 Whatman) column pre-equilibrated in the same buffer. The column was developed with buffer A and a linear salt gradient of 50–300 mM KCl. At this point, TF-B was 100-fold purified and contained <5% contaminating TF-C activity and no detectable TF-A activity. After the elution of TF-B, the phosphocellulose column was washed extensively with buffer A and 350 mM KCl. TF-C activity was then step eluted with buffer A and 600 mM KCl. Protein-containing fractions were pooled and dialysed for 8 h against buffer A and 200 mM KCl. The dialysate was loaded onto a native DNA cellulose column pre-equilibrated in the same buffer. The column was developed with buffer A and 1 M KCl. Protein-containing fractions were dialysed for 8 h against buffer A and 200 mM KCl. At this point, TF-C was purified 250-fold and contained < 5% contaminating TF-B and no detectable TF-A activity. Both TF-B and TF-C contained endogenous RNA polymerase III as measured by a nonspecific template assay[28]. The addition of purified RNA polymerase III had little effect on TF activity in the conditions used in our experiments. The standard transcription reactions were in a final vol. of 50 μl and contained 20 mM HEPES *p*H 7.5, 10% glycerol, 5 mM $MgCl_2$, 66 mM KCl, 0.5 mM DTT, 200 μM of rATP, CTP, GTP and UTP, 0.8 μg of plasmid or λ clone DNA, 2.5 μl TF-C and 12 μl TF-B. Incubations were carried out at 23 °C for 1 h and were terminated by phenol extraction. The reactions were ethanol precipitated and the pellet was resuspended in 10 mM Tris, 1 mM EDTA. The RNA was then assayed by primer extension analysis as described in Fig. 3 legend. Primer extension products were sized by electrophoresis alongside a sequencing ladder of known sequence.

In the cytoplasm, *B2* sequences are found mainly in RNAs of low relative molecular mass that are not associated with polysomes[6], but can also be present in larger, polysome-associated mRNAs at the 3′-untranslated end of the transcript[7–12]. The cloned *B2* repeat in 10λ5 appears part of a larger transcript, as there is 450 bp of sequence 5′ to the *B2* repeat. Figure 2*b* compares the 10λ5 *B2* sequence with the consensus *B2* sequence[4].

The homologies to the polymerase III promoter sequences[13] within the *B2* consensus sequence suggested that the small RNAs may be polymerase III transcripts. The heterogeneous nature of these RNAs could be a result of faithful initiation but irregular termination of transcription. Our examination of the sequence of a number of *B2* elements shows that only a subset contains an efficient polymerase III terminator—a cluster of four or more T residues surrounded by G+C-rich sequences[14]. Accordingly, one would then expect these cytoplasmic *B2* RNAs to have similar 5′ ends and these ends to map near the 5′ end of the element, because all polymerase III transcripts except for 5S RNA start 10–20 nucleotides upstream from the A box[15].

We tested this hypothesis using primer extension. As a primer we used a 55-bp *B2*-specific fragment from 10λ5. The 5′ end of the primer is located 31 bp downstream from the putative A box in the *B2* consensus sequence and 55 bp downstream from the 5′ end of the element (see Fig. 2*b*). We annealed this primer to total cytoplasmic RNA and extended the hybrids with reverse transcriptase as shown schematically in Fig. 3*c*. We find two major extension products 109 and 110 bp in size (Fig. 3*b*), which shows that the 5′ ends of the mature cytoplasmic *B2* RNAs are located 12 and 13 nucleotides upstream from the A box. This result strongly suggests that the small cytoplasmic *B2* RNAs are polymerase III transcripts.

To corroborate this conclusion, we used a partially purified polymerase III transcription system to transcribe two clones, pH-2^d-1 (ref. 8) and λ27.1 (ref. 7), which contained *B2* elements. Transcription of polymerase III genes with split promoters such as transfer RNA genes and the adenovirus virus-associated (VA) genes requires, in addition to polymerase III, transcription factors B and C (TF-B and TF-C)[16]. Primer extension analysis revealed that neither pH-2^d-1 or λ27.1 was an effective template for polymerase III unless the reaction mix also contained both TF-B and TF-C (Fig. 4*a*, lanes 3–5 for pH-2^d-1 and lanes 6–8 for λ27.1). The 5′ ends of the *B2* RNAs produced *in vitro* (Fig. 4*a*, lanes 5, 8) align closely with the 5′ ends of the *in vivo B2* RNAs (Fig. 4*a*, lane 2). Figure 4*b* summarizes these *in vitro* and *in vivo* start positions. Finally, λ27.1 was incubated with polymerase III, TF-B and TF-C in the presence of 2 μg ml^{-1} (Fig. 4*a*, lane 9) and 200 μg ml^{-1} (Fig. 4*a*, lane 10) of α-amanitin. The lower level inhibits polymerase II transcription while the higher level inhibits polymerase III[29]. Whereas 2 μg ml^{-1} of α-amanitin has no effect on *B2* transcription, 200 μg ml^{-1} is completely inhibitory.

The transcription factor requirements and the α-amanitin sensitivity indicate clearly that the mouse *B2* elements we have

studied are transcribed by polymerase III *in vitro*. In this respect, the mouse *B2* family is equivalent to various other *Alu*-like sequences known to be polymerase III templates *in vitro* (for review see ref. 17). Our primer extension analysis of cytoplasmic RNA shows that these repeats are also functioning as expressed polymerase III genes *in vivo*. *B2* RNA sequences can therefore arise as parts of polymerase II transcripts when the repeat is present within a polymerase II transcription unit, or they can be expressed independently by their own polymerase III promoters.

We have also studied 5S RNA gene expression and find no significant difference in the cytoplasmic levels of the 5S RNAs between the parental cell line and the SV40-transformed derivative (data not shown). Thus, there is no generalized induction of polymerase III transcription in SV40-transformed cells. Evidence for the regulation of specific polymerase III transcripts already exists for the expression of the oocyte-specific 5S genes in *Xenopus* (for review see ref. 18), and the brain-specific expression of the rat ID sequences[19,20]. Moreover, it has recently been shown that E1A induction of adenovirus VA RNAs is at least in part due to elevated levels of polymerase III transcription factor C (W. K. Hoeffler and R. G. Roeder, and S. Yoshinaga and A. Berk, personal communications). If the induction of the *B2* RNAs is at the level of transcription, this would suggest the presence of a polymerase III transcription factor(s) whose activity is sensitive to growth conditions and oncogenic transformation. It may be that the majority of the *B2* repeats, like similar highly repeated *Alu*-like sequences, have no useful function in the cell and have simply keyed themselves into a growth-sensitive polymerase III transcription system. Thus, other templates for this system could also exist and these may have physiologically more important roles for the rapidly dividing cell. It will therefore be interesting to study how other polymerase III transcripts such as the small 7SL RNA involved in secretion[21], tRNAs or 4.5S RNAs are affected by transformation.

We thank Drs P. Kourilsky, R. Goodenow and D. Bogenhagen for plasmid pH-2^d-1, phage λ27.1 and plasmid pXbs-73x201, respectively, Drs D. Brutlag and F. Doolittle for conducting computer searches for DNA sequence homology to the clone 10λ5 and Dr N. Cozzarelli for help in monitoring and isolating polymerase III transcription factors and helpful comments on the manuscript. S.S. was supported by a fellowship from La Ligue Nationale Française contre le Cancer. This work was supported by grant CA 30490 from the National Cancer Institute and grant MV-91 from the American Cancer Society to M.B., and by NIH grant GM 31657 to N. Cozzarelli.

Transposons are discrete segments of DNA which are capable of moving from one site in a genome to many different sites[1,2]. Tn*3* is a prokaryotic transposon which is 4,957 base pairs (bp) long and encodes a transposase protein which is essential for transposition[3–7]. We report here a simple method for purifying Tn*3* transposase and demonstrate that the transposase protein binds specifically to the ends of the Tn*3* transposon in an ATP-dependent manner. The transposase protein binds to linear double-stranded DNA both nonspecifically and specifically; the nonspecific DNA binding activity is sensitive to challenge with heparin. Site-specific DNA binding to the ends (inverted repeats) of Tn*3* is observed only when binding is performed in the presence of ATP; this ATP-dependent site-specific DNA binding activity is resistant to heparin challenge. Our results indicate that ATP qualitatively alters the DNA binding activity of the transposase protein so that the protein is able to bind specifically to the ends of the Tn*3* transposon.

DNA sequence analysis reveals that the Tn*3* transposase coding frame is 3,012 bp in length, which would allow for a protein of relative molecular mass (M_r) ~113,000 (113K). This size estimate agrees well with results obtained in experiments where Tn*3*-specific proteins have been identified by radioactive labelling in the minicell strain DS410 (refs 7–9). The purification of Tn*3* transposase was first reported by Fennewald *et al.*[10]. This protein exhibited a heat-sensitive nonspecific single- and double-stranded DNA binding activity. However, no additional enzymatic activities associated with the Tn*3* transposase protein have been reported. To learn more about the Tn*3* transposase, we devised a simpler purification scheme than that reported previously[10]. Our purification was facilitated by the observation that the wild-type transposase protein accumulates to ~1.5% of total cell protein when a plasmid bearing a Tn*3* repressor mutant (pMB8:Tn*3*$^{\circ}$5)[6], which transposes at a high frequency[6,11], is grown in minicell strain DS410[12,13] (Fig. 1).

Briefly, our method consists of four essential steps: membrane extraction, polyethyleneimine precipitation, step dialysis and separation by phosphocellulose chromotography. The method is simple, rapid, gentle and yields milligram quantities of transposase protein (see Fig. 2). The identity of the transposase protein was confirmed by amino-acid analysis and N-terminal sequence analysis performed at the Brookhaven protein sequencing facility at Brookhaven National Laboratories (unpublished data), and our results agree with those reported by Ditto *et al.*[14].

The transposase protein isolated in this manner binds nonspecifically to linear DNA fragments (Fig. 3); this DNA binding activity can be abolished by the addition of heparin, a mucopolysaccharide which competes with DNA for DNA binding sites. We used an assay essentially identical to that described by Wishart *et al.*[15]. The transposase protein is added together with DNA fragments in 250 μl of binding buffer (10 mM $MgCl_2$, 10 μg ml^{-1} bovine serum albumin, 100 mM KCl, 10 mM Tris-HCl *p*H 7.6, 0.1 mM dithiothreitol and 0.1 mM EDTA), ATP and heparin as described in Fig. 3 legend. The mixture is then incubated at 27 °C for 5 min and filtered through nitrocellulose filters. In our binding conditions, the transposase protein is retained quantitatively on the filters together with any DNA fragment to which the protein has bound, while unbound DNA fragments flow through. Filters are then washed extensively with binding buffer, and DNA fragments, retained on the filter by

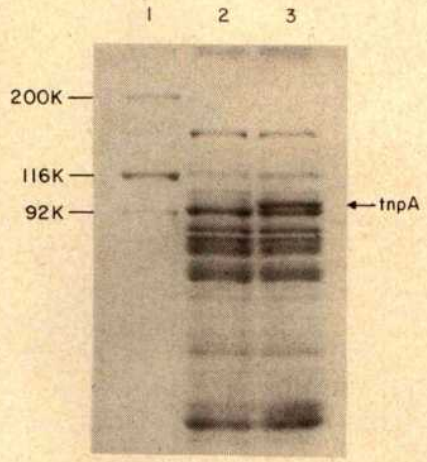

Fig. 1 Transposase protein accumulates in DS410 minicells. Lane 1 contains BioRad high-M_r markers as indicated. Proteins synthesized in DS410 cells containing pMB8:Tn*3* 72 (lane 2; transposase-negative)[6] or pMB:Tn*3* 5 (lane 3; transposase-positive)[6] were separated on a 10% polyacrylamide gel and stained with Coomassie brilliant blue. The transposase band (tnpA) is clearly visible.

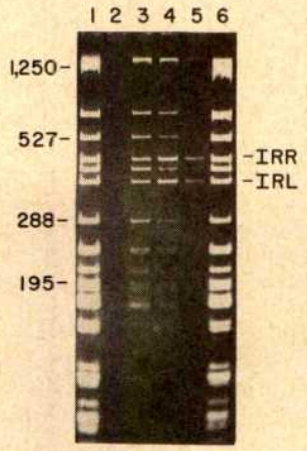

Fig. 3 Transposase binds to linear double-stranded DNA fragments. Lanes 1, 6, marker lanes of pMB::Tn*3* digested with *Hpa*II. Lanes 2–5, HpaII fragments retained on nitrocellulose filters in the presence, respectively of 0 μg transposase, 2.5 μg transposase, 2.5 μg transposase plus 8 mM ATP, and 2.5 μg transposase plus 10 μg ml^{-1} heparin with 8 mM ATP. Representative fragment sizes are indicated in base pairs. The fragments containing the Tn*3* left (IRL) and right (IRR) inverted repeats are also indicated.

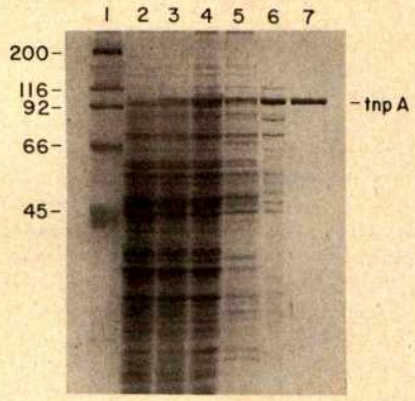

Fig. 2 Purification of the Tn*3* transposase. Protein samples obtained at various steps in the purification scheme were separated on a 10% polyacrylamide gel and stained with Coomassie brilliant blue. Lane 1, BioRad high-M_r protein markers ($\times 10^{-3}$) as indicated; lane 2, total cell lysate from transposase-negative control strain pMB:Tn*3* 72/DS410; lane 3, marker total cell lysate from transposase-overexpressing strain pMB:Tn*3* 5/DS410; lane 4, total cell lysate from transposase-overproducing strain pMB:Tn*3* 5/DS410 from which transposase was purified; lane 5, proteins extracted from membrane fraction with 2% Triton X-100; lane 6, nucleic acid binding proteins from the membrane fraction were precipitated by adding polyethyleneimine (final concentration 1.5%), the pellet was then extracted with 1 M ammonium sulphate, the extract was step-dialysed to remove ammonium sulphate, and proteins which precipitated in the 50–20 mM ammonium sulphate step were run in this lane; lane 7, transposase protein (4 μg) eluted from a phosphocellulose column via a linear gradient of 50 mM to 1 M potassium phosphate.

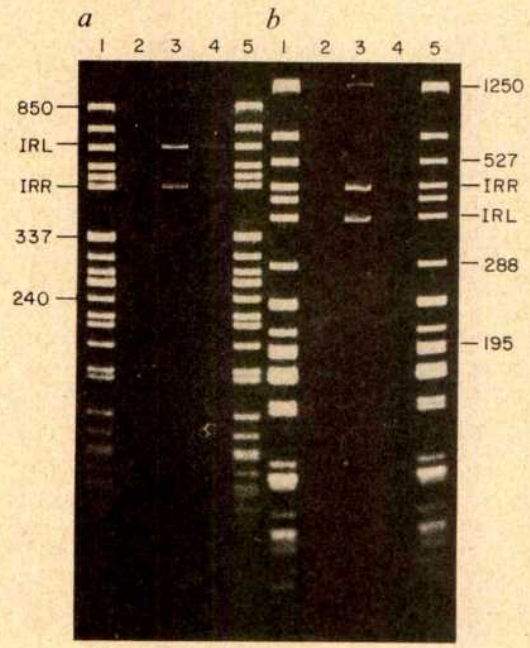

Fig. 4 Transposase site-specific DNA binding with DNA from *Cfo*I (*a*) and *Hpa*II (*b*) digestions of pMB8::Tn*3*; *a*, lanes 1, 5, *Cfo*I digestions of pMB8::Tn*3* lanes 2–4, *Cfo*I DNA fragments bound in the presence of 0 μg transposase, 2.5 μg transposase with 8 mM ATP, and 2.5 μg transposase with 16 mM ATP, respectively. *b*, Lanes 1, 5, *Hpa*II digestions of pMB8::Tn*3*, lanes 2–4, DNA fragments bound in conditions identical to those in *a*, lanes 2–4, respectively.

binding to the transposase protein, are eluted in 1 ml elution buffer (0.2% SDS, 30 mM Tris-HCl *p*H 7.6), ethanol-precipitated, and run on polyacrylamide gels next to marker digestions of the plasmid from which the original DNA (pMB:Tn*3* digested with *Hpa*II) was obtained. The results of these experiments indicate whether or not the transposase is able to bind to DNA and also provide information about binding specificity, as DNA fragments retained by the transposase protein can be compared directly with the original DNA fragments.

Because Tn*3* moves as a non-permuted element, that is, the linear arrangement of the transposon is unchanged during transposition[16], some factor must exist which is able to recognize the ends of the transposon as a first step in the transposition process. As the transposase is known[17] to be required for transposition of Tn*3* and as the transposase is known to act in *trans*[2,17], it is logical that such a site-specific binding activity capable of recognizing the ends of Tn*3* might reside in the transposase protein.

To determine whether or not the transposase possessed the ability to bind specifically to the ends of the Tn*3* transposon, we performed the above binding assay in a variety of conditions. Altering KCl, $MgCl_2$ and heparin concentrations affected the relative efficiency of binding, but no specific binding of DNA fragments containing the inverted repeats of Tn*3* was observed. Altering binding time or protein/DNA ratios also had no effect on binding specificity (data not shown).

Because some of the enzymes involved in DNA replication and recombination have been shown to use ATP as a free energy source[18,19], we added ATP to our reaction mixture to determine whether ATP might affect the DNA binding activity of the transposase protein. We found that ATP produced a dramatic change in DNA binding activity; in the presence of 8 mM ATP, the transposase protein was able to bind specifically to DNA fragments containing the ends of the Tn*3* transposon in a complex which was resistant to challenge with 10 $\mu g\ ml^{-1}$ heparin (Fig. 3, lanes 4, 5). In the absence of ATP, all DNA fragments could be removed from the transposase protein simply by adding heparin to 10 $\mu g\ ml^{-1}$, and no specific DNA binding was observed. In the presence of 8 mM ATP, fragments containing the 38-bp inverted terminal repeats of the Tn*3* transposon remained bound to the transposase protein even in the presence of 10 $\mu g\ ml^{-1}$ heparin (Fig. 3, lane 5; Fig. 4*b*, lanes 1-5).

The specificity of this binding activity was confirmed by repeating the experiment using pMB8:Tn*3* DNA digested with a different enzyme, *Cfo*I. Again, only the fragments containing the Tn*3* inverted repeats were retained on filters in the presence of ATP and heparin (Fig. 4*a*, lanes 1-5).

Our results suggest that ATP qualitatively alters the binding specificity of the transposase protein. However, one alternative explanation is that more than one DNA binding site exists on the transposase protein, only one or a few of which are capable of binding to the ends of the Tn*3* transposon. In this case, the ATP might not be required directly for recognition of the Tn*3* inverted repeats, but might merely decrease the nonspecific DNA binding activity relative to site-specific DNA binding activity. However, this seems not to be the case because, at a heparin concentration of 10 $\mu g\ ml^{-1}$, in the absence of ATP, all DNA fragments are competitively removed and no binding specificity is observed.

It is possible that ATP addition alters metal concentrations, causing the transposase protein to bind specifically to the inverted repeats of Tn*3*. Preliminary results from experiments in which residual magnesium was removed by the addition of EDTA to 25 mM indicate that magnesium is not essential for specific binding of the transposase protein, although it does seem to increase the efficiency with which the transposase protein binds to the DNA fragments containing an inverted repeat.

As transposons promote non-homologous genomic rearrangements, they are believed to be evolutionarily significant. Our finding that the transposase is capable of binding to the ends of the Tn*3* transposon and that this binding is specifically affected by ATP is exciting in that it suggests that ATP might be fuelling at least the initial step in the transposition mechanism (that is, recognition of the ends of the transposon by the transposase). We are now attempting to analyse the nature of this effect of ATP on binding specificity in greater detail. We are also investigating other transposition-related activities which current models[20-22] for the molecular mechanism of Tn*3* transposition would predict to be associated with an active transposase or transposase complex.

We thank Dr Fred Heffron for providing the Tn*3* mutants, Drs Marshal Elzinga and Nick Alonzo for the amino-acid analysis and protein sequencing, and Drs David Shortle, Don Oliver, Karen Armstrong, Robert Cabelli and Laura Liss for advice. W.L.W. was supported by NIH training grant CA09176.

Domains of action of *bithorax* genes in *Drosophila* central nervous system

Erik Teugels & Alain Ghysen

Laboratoire de Génétique, Université Libre de Bruxelles, 67, rue des Chevaux, 1640 Rhode-St-Genèse, Belgium

The diversification of all *Drosophila* segments posterior to the mesothorax is controlled by a single gene cluster, the bithorax complex (BX-C)[1]. Various observations have led to the conclusion that the BX-C is involved in the segmental determination of both the central nervous system (CNS) and the epidermis[1-6]. In general, the neural and epidermal effects of a given BX-C mutation were found to occur in the same segment. However, only one neural structure was examined in each of these experiments; furthermore, the segmental origin of these few structures was in most cases unclear, making it impossible to decide whether or not the action of the BX-C genes is confined to the same regions in the epidermis and the CNS. Here we describe a set of 18 uniquely recognizable fascicles in the adult CNS, and establish the segmental origin of each of them. We analyse the effect of different BX-C mutations on these fascicles, and show that each mutation affects a region that overlaps two consecutive segments. We conclude that in the CNS, the spatial domains of action of BX-C genes are segment-length units which are out of register with the epidermal segments.

The problem of defining the spatial domains of action of BX-C genes in the adult CNS is complicated by two facts. First, there has been a tendency towards the condensation of the CNS during insect evolution. Whereas in primitive insects the segmental ganglia are clearly separated, in flies the thoracic and abdominal ganglia fuse to form a single ventral ganglion with no detectable intersegmental boundaries. Second, very few segment-specific structures have been identified in the CNS of *Drosophila*, and therefore the description of the segmental transformations associated with a given BX-C mutation is severely limited. We have overcome both difficulties by studying the pattern of transversal commissures in the CNS of adult flies, using a monoclonal antibody (5D12, isolated by Y. N. Jan and L. Y. Jan) which labels a set of transversal fascicles at all developmental stages (Fig. 1). Other labelled structures are also present in the adult CNS (Fig. 1*d*-*f*), but will not be dealt with here. Early during neurogenesis, two transversal commissures, one anterior and one posterior, are formed within each segmental ganglion, both in *Drosophila*[7] and in the grasshopper[8] (Fig. 1*a*). In the grasshopper[8,9] and probably also in *Drosophila*[10], these two commissures are pioneered by neurones belonging to the same segmental ganglion. By the end of embryonic development, a number of different fascicles can be distinguished in each of these two commissures by using antibody

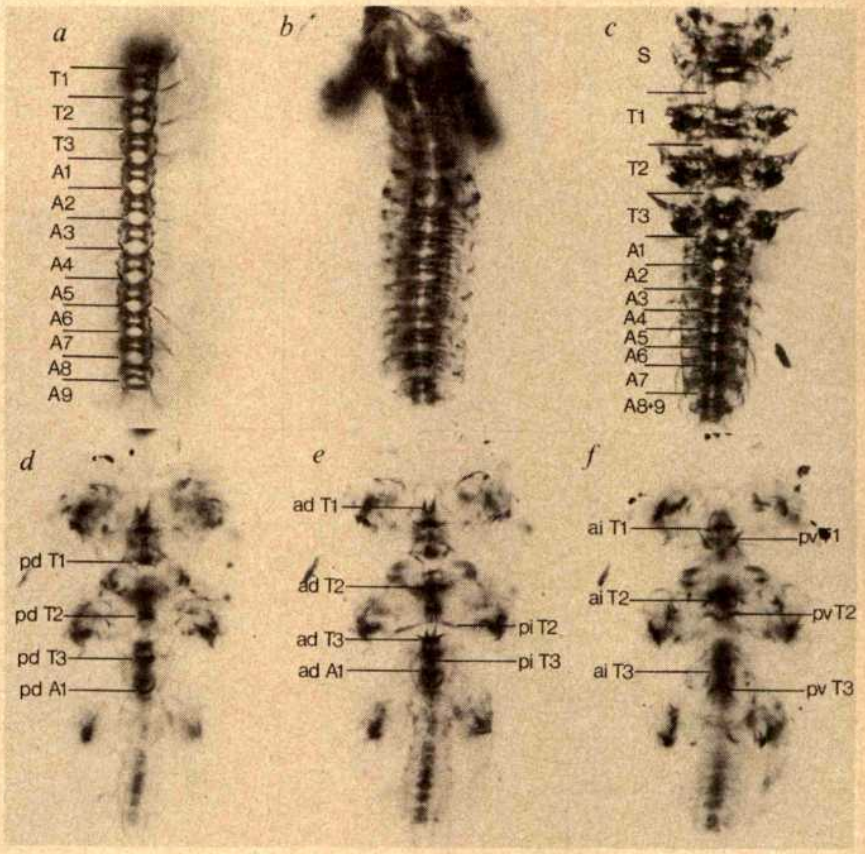

Fig. 1 The development of transversal fascicles revealed by antibody 5D12. *a*, CNS of a 12-h-old embryo. One anterior and one posterior commissure are seen in the three thoracic (T1–T3) and eight abdominal (A1–A8) segments. The ninth abdominal ganglion (A9) contains only one commissure. The three suboesophageal ganglia and the brain stems are out of focus. *b*, CNS of an early first-instar larva. Various distinct fascicles, only some of which are in focus in this photograph, can be distinguished within each commissure. *c*, CNS of a 9-h-old pupa. The major changes that will lead to the adult pattern have only just begun and the suboesophageal ganglia are still closely apposed to the thoracic ganglia. The organization of the fascicles in two clusters, one anterior and one posterior, can still be detected. *d*, Adult CNS, dorsal focal plane. *e*, Adult CNS, intermediate focal plane. *f*, Adult CNS, ventral focal plane. Most of the adult fascicles studied in the mutants can be detected, although some are slightly out of focus (compare with Fig. 2, bottom row). Abbreviations: ad, anterior dorsal fascicle; ai, anterior intermediate fascicle; av, anterior ventral fascicle; pd, posterior dorsal fascicle; pi, posterior intermediate fascicle; pv, posterior ventral fascicle.

Method. In all cases, the staining was done on formaldehyde-fixed nervous systems except for *a*, where heptane/formaldehyde-fixed whole embryos were used. The dissection, fixation and rinse were performed in phosphate buffer 0.1 M, *p*H 7.6. All the following steps were each performed for 6 h in the same buffer containing 0.3% deoxycholate and 0.3% Triton (PDT buffer): The samples were incubated in antibody 5D12 (1:10 in PTD containing 10% of normal goat serum), rinsed in PDT, incubated with biotinylated secondary antibody (1:200 in PDT), rinsed in PDT, incubated in avidin biotinylated peroxidase (1:1:100 in PDT) and rinsed in PDT. For larval ganglia, the incubation times were reduced to 3 h instead of 6 h. All secondary immunoreagents were from Vector Labs. The samples were then processed for peroxidase staining, dehydrated, cleared and mounted. The adult ganglion was understained for photograph purposes.

5D12 (Fig. 1*b*). Little change is observed in this pattern up to the early pupal stage (Fig. 1*c*), but during the next 2 days most of the abdominal fasicles disappear and the thoracic fascicles undergo major modifications such that the segmental origins of the adult structures become less clear (Fig. 1*d*–*f*). However, by studying intermediate pupal stages, we have been able to follow the fate of a given fascicle throughout metamorphosis (Fig. 2) and have traced all the transversal fascicles that we detect in the adult CNS to the anterior or posterior embryonic commissure of a particular segment.

To simplify the description of mutant phenotypes, we have assigned a symbol to each adult fascicle within a given segment. The symbol summarizes the origin of the fascicle ('a' or 'p' for fascicles derived from the anterior and posterior embryonic commissures) and its position within the adult ganglion ('v', 'i' or 'd' for ventral, intermediate or dorsal). Some fascicles revealed by antibody 5D12 still show a clear homology from segment to segment in the adult, and will not be considered further. However, most of them have assumed segment-specific shapes in the adult (for example, compare the ad fascicles in segments T1, T2, T3 and A1; Fig. 2) thereby enabling us to determine the effect of BX-C mutations on this process of segmental diversification.

We have examined how this unique pattern of fascicles is affected by mutations in three consecutive regions of the BX-C: the *Ubx*, *bxd* and *iab-2* regions (Table 1, Fig. 3).

All recessive mutations in the *Ubx* region[11] produce transformation of the anterior metathorax (T3) into an anterior mesothorax (T2) in the epidermis. Two classes of mutations, *bx* and *abx*, have been distinguished on the basis of their localization, partial complementation and minute differences in

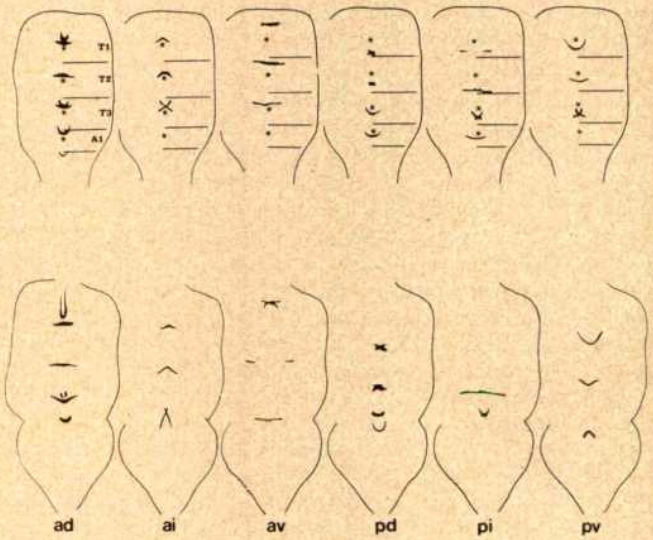

Fig. 2 Metamorphosis of the CNS. The transformation of the larval pattern into the adult pattern was followed at 9, 15, 20, 24, 48 and 73 h after the onset of metamorphosis. The first line of pictures are camera lucida drawings of a CNS during early metamorphosis (15 h APF); the second line shows drawings of the adult pattern. Each row indicates the segmental homologues for one of the fascicles studied in this paper. In the pupal CNS, the large gap between commissures belonging to consecutive segments is marked by a line; the smaller gap between the anterior and posterior commissures within a segment is marked by an asterisk. Abbreviations as in Fig. 1.

The extent and frequency of the transformations are represented as follows. + Represents a rather complete transformation, +/− represents a partial transformation. In the latter case, either a fascicle is of an intermediate type or more often a normal and a transformed fascicle coexist. In one case (ai A1 in *pbx/Df*), +/− represents an additional fascicle that resembles not the adult ai T3, but its early pupal stage (see Fig. 2). Bold type indicates that the effect was seen in all mutants, normal type indicates an effect observed in a majority of the cases, and parentheses indicate an occasional effect. The results obtained with different genotypes were pooled whenever the results appeared to be identical. The lower half of the table shows the genotypes and numbers of nervous systems analysed.

phenotype[12]. We examined four mutations in this *Ubx* region: two *bx* alleles, bx^3 and bx^{34e}, and two *abx* alleles, abx^1 and abx^2. None of the *bx* mutations gave any detectable effect on any fascicle, other than an occasional slight malformation of ad T3 in bx^{34e} hemizygous flies. This is perhaps not surprising in view of the fact that *bx* mutations, and in particular bx^3, have been reported to have no effect on sensory neurones[13,14], and at most a minimal effect on the CNS[15,16]. On the other hand, both *abx* alleles have a marked effect on one mesothoracic fascicle (pi T2) and on three metathoracic fascicles (ad, av and pd T3). These effects are detected in homozygous as well as hemizygous flies. In addition, a slight effect on pi T3 can be detected in some hemizygous abx^2 flies.

Two classes of recessive mutations are known in the *bxd* region[11]; *bxd* mutations transform the anterior first abdominal segment (A1) into an anterior T3, and to a lesser extent the posterior T3 into a posterior T2, while *pbx* mutations show only the latter transformation[17]. We examined four mutants in the *bxd–pbx* region: two extreme *bxd* alleles, bxd^{100} and bxd^{125}, and the two existing *pbx* alleles, pbx^1 and pbx^2. Both *bxd* mutations had a marked effect on two metathoracic fascicles (pi and pv T3) and on four first abdominal fascicles (ad, ai, av and pd A1), while a weaker effect was occasionally observed on pd T3. These effects were observed in heterozygous bxd^{100}/bxd^{125} as well as in hemizygous flies. The two *pbx* alleles showed essentially no phenotype when homozygous or when combined with a deficiency for the *Ubx* region (and part of the *bxd* region), $Df(3R)bxd^{100}$. However, they caused clear transformations when combined with a larger deficiency deleting the entire *Ubx–bxd* region (and part of the *iab-2* region), *Df(3R)P10*. In this combination, *pbx* also affected both metathoracic (pi T3, and occasionally pd t3) and first abdominal (ad A1, and to a lesser extent ai A1) fascicles.

Extreme *iab-2* mutations, like *TP10*, are embryonic lethal when homozygous. Whether or not this boundary coincides with a compartment boundary cannot be decided, since it is not known if compartments exist in the CNS. However, the analysis of mutant embryos revealed that the anterior part of the second abdominal segment (A2) is transformed into A1 (ref. 18). In the CNS, however, transformations were observed even in *TP*10/+ heterozygotes, indicating haplo-insufficiency for $iab\text{-}2^+$. In this case, the mutant phenotype does not lie in the transformation of existing fascicles, but in the persistence of abdominal fascicles that are normally suppressed during metamorphosis. Here again, the effect is seen in two consecutive segments; an additional pi fascicle is usually present in A1, and additional ad and pd fascicles are often observed in A2.

We conclude that the defects corresponding respectively to the *abx*, *bxd* and *iab-2* mutations define three consecutive regions in the CNS; their boundaries do not coincide with segmental boundaries, as in each case fascicles belonging to two different segments were affected. The linear order of these regions is entirely consistent with the observation made by Lewis[1] that consecutive genes in the BX-C are required in consecutive regions of the body, and indicates that the expression of the BX-C largely follows the same sequential

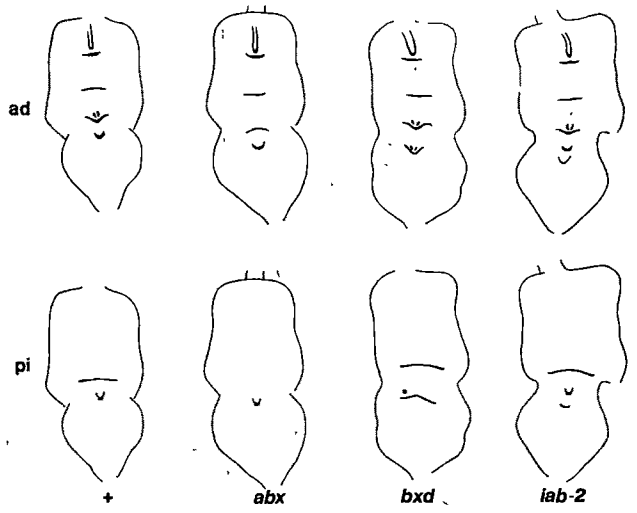

Fig. 3 Effect of BX-C mutants on the adult fascicles. The transformations undergone by two fascicles, an anterior one (ad) and a posterior one (pi), are illustrated for mutations in each of the three regions examined. *abx*: $abx^1/Df(3R)bxd^{100}$ flies; *bxd*: bxd^{100}/bxd^{125}; *iab-2*: *T(2;3)P10/+*. In all cases, the modification results in a fascicle resembling that of the anterior segment. Thus, in some cases the shape of the fascicle is changed (for example pi T3 in bxd); in some cases the fascicle disappears (for example pi T2 in *abx*); and in some an additional fascicle is formed (for example, pi A1 in *iab-2*). All figures are camera lucida drawings; for each genotype, we used a ganglion which showed a complete transformation; see Table 1 for the frequency of the different transformations in each genotype.

strategy in the epidermis and the CNS. The fact that the boundaries of these regions do not coincide with segmental boundaries clearly supports the 'frameshift' hypothesis proposed by Lewis[19] that the posterior regions of segments 'appear, in the presence of the mutants, to behave as though they were embryologically related to the anterior portion of the segment that follows, rather than precedes, them'. According to this hypothesis, the genes of the BX-C would act on segment-length units which include the posterior portion of one segment and the anterior portion of the following segment, and therefore are out of register with the segments themselves. In the case of the Ubx^+ gene analysis of the distribution of Ubx proteins in the CNS has provided a direct confirmation of this hypothesis[20,21].

The epidermal segments consist of two compartments, one anterior and one posterior[22]. It has been hypothesized that compartments rather than segments are the basic units of development[23], and that the limits of the domains of action of BX-C genes coincide with compartment boundaries[22,24,25]. Struhl[24] has recently rephrased the frameshift hypothesis in terms of compartments on the basis of his and other[26] results. Thus, the realm of action of BX-C genes would extend from an antero-posterior compartment boundary to the next one, and therefore include the posterior compartment of one segment and the anterior compartment of the following segment.

In the CNS, the three domains of action defined respectively by the *abx*, *bxd* and *iab-2* mutations extend from a posterior fascicle (pi) to another posterior fascicle (pd Table 1), implying that the limits of the domains are located in the posterior commissure. The observation that pd T3 is occasionally affected in *bxd* mutants suggests that pd may be at the very boundary between consecutive domains. Whether or not this boundary coincides with a compartment boundary cannot be decided, since it is not known if compartments exist in the CNS. However, the analysis of mutant phenotypes indicates that each transformation affects an entire segment-length unit. This result is particularly interesting in the phase of the *pbx* and *bxd* mutations, which in the adult epidermis affect predominantly the posterior T3 and anterior A1, respectively[1,17,27]. Our results revealed no clear difference in the domain of action of *pbx* and *bxd*. Thus, in different *pbx* combinations, whenever a transformation was detected, it affected fascicles on both sides of the T3–A1 segmental boundary. Similarly, when we reduced the *bxd* phenotype by using leaky *bxd* mutations the transformations in T3 and A1 were affected equally (Table 1). This indicates that a compartmental specificity of BX-C mutations similar to that observed in the epidermis is not readily detectable in the CNS. Thus, if compartments exist in the CNS, they do not seem to be important in the pattern of expression of BX-C genes.

We conclude that in the CNS, BX-C mutations affect entire segment-length units, suggesting that the domains of action of BX-C genes define 'genetic segments', similar to the morphological segments in their size but not in their boundaries. We emphasize, however, that our conclusions hold only for neurones involved in the diversification of the transversal fascicles labelled by 5D12; other structures may reveal a different pattern.

We thank Drs Y.N. and L. Y. Jan for allowing us to use their monoclonal antibody 5D12. We also thank E. Lewis for mutant strains, C. Goodman for discussion, P. Beachy and C. Dambly-Chaudière for improving the manuscript and R. Thomas for support. This work was supported by a FNRS research grant. E.T. is fellow of the IRSIA and A.G. is chercheur qualifié of the FNRS (Belgium).

Erratum

Change in motion of Pacific plate at 5 Myr BP

A. Cox & D. Engebretson
Nature **313**, 472–474 (1985)

ON page 472, the last line of the fourth paragraph was deleted. The second sentence should read: "In offshore basins in central California, there is further tectonic evidence for a component of plate convergence across the San Andreas fault beginning at ~5.5 Myr[4]."

This should be followed by a new paragraph beginning: "Along the Pacific/Juan de Fuca (PA-JF) spreading centre, two major shifts in rotation poles occurred..."

Model for Grampian tract evolution

DEWEY and Shackleton's stimulating and provocative model for the evolution of the Grampian tract of the Caledonide-Appalachian orogen[1] postulates subduction towards the south-east between about 510 Myr BP and at least 470 Myr BP. As a result, they reject previous suggestions that the extensive layered mafic and ultramafic intrusions of Connemara and north-east Scotland were emplaced (at 485–500 Myr BP) above a north-west-dipping subduction zone and formed the roots of Andean-type volcanic arcs[2] or the lower parts of batholiths, subsequently removed during Upper Ordovician erosion[3]. The more mafic of these plutons contain cumulus assemblages of the minerals olivine plus chromite, followed by magnesian ortho- and clinopyroxene, very calcic plagioclase, and interstitial primary amphibole—inferred to precipitate at deep-crust levels within island arcs from subduction-related, silica-saturated hydrous magnesian magmas[4,5].

Figure 1 shows normalized incompatible trace elements in samples of each complex that have essentially escaped both the interaction with upper-crust metasediments and the Grampian deformation and metamorphism that affects most of them. Subduction-related basalts from Japan and Vanuatu are also plotted in Fig. 1. The essential similarities of many inter-element ratios between these modern circum-Pacific island-arc lavas and the Ordovician plutons are clear. As a group, the trace-element patterns (Fig. 1) of these samples are characteristic of subduction-related magmas worldwide and are quite different from those erupted in other tectonic environments, such as strike-slip pull-aparts, which Dewey and Shackleton suggest as an alternative. A Recent basanite from Dish Hill, Southern California (Fig. 1) is a typical example of the predominant type of basic magmatism in the south-west USA, extruded since the inception of a strike-slip plate boundary in this region.

Dewey and Shackleton have commented[1] that their "model is invalid, at least for the British Isles", if these Lower Ordovician plutons are subduction-related. I agree that more research is needed, but nevertheless, emphasize that there is already sufficient knowledge of the geochemistry of Lower Ordovician magmatism in the Caledonian–Appalachian orogen that the data from this approach cannot be ignored when constructing overall models.

DEWEY AND SHACKLETON REPLY—We thank Thompson for his geochemical data and conclusions and agree that a successful model for the evolution of the Grampian tract must account for geochemical and petrological data. Clearly, from the perspective of incompatible element pattern recognition, the Connemara and Banffshire intrusions are similar to the magmatic rocks of some modern arcs, but our lack of geochemical expertise disqualifies us from commenting on that data. However, we note that calc-alkaline magmatism occurs in a wide variety of non-arc settings including collisional environments such as eastern Anatolia. An important mechanism in collisional orogens is lithospheric delamination[1], which allows hot fertile mantle to gain access to levels as high as the base of a thickened crust. This causes rapid uplift and denudation and a surge of mafic magmatism and possibly partial melting of a mafic lower crust. We suggest that such a mechanism was responsible for the Grampian mafic intrusions. Our use of the term 'pull-apart' is simply kinematic and does not imply a particular regional tectonic setting. Pull-aparts in strike-slip systems occur in almost every type of regional tectonic environment including island arcs. In collisional systems, they may localize calc-alkaline magmatic rocks (for example, Erzinçan basin on the North Anatolian Fault). A particular problem with the Connemara intrusions is that we know little of their original form and intrusive mechanism, though they appear to have a regionally disrupted sheet-like form. A particular problem in considering the intrusions as arc roots is that they were intruded into a pile of nappes during the latest stages of shortening. A West Pacific model, therefore, seems inappropriate because most of the West Pacific is in deviatoric tension where shortening is rare.

Lastly, the model is developed largely from data for Newfoundland where it seems difficult to refute, and then extrapolated to the British Isles. It is quite certain that the obduction model in its simplest form cannot account for the Taconian events of the Appalachians south of Quebec, because the tell-tale mafic detritus, particularly chromite, is virtually absent from the Taconic flysch belt in the US Appalachians. Hence, although it is also possible that the obduction model is inappropriate for the early Caledonides and is unique to the Canadian Appalachians, we cannot yet think of a better model.

CURRENT THEMES IN PSYCHIATRY: Volume 3

ed. Raghu N. Gaind, Fawzy I. Fawzy, Barbara L. Hudson & Robert O. Pasnau

1 Psychological Aspects of Physical Illness 2. The Assessment of Dementia 3. Schizophrenia Succeeded by Affective Disorder 4. Drugs and Sexual Dysfunction 5. Who Needs Psychiatry, Anyway? 6. The Psychopharmacology of Aggression 7. Drug Treatment in the Elderly 8. Care of the Elderly Psychiatric Patient in the US 9. The Future of Liaison Psychiatry in the US 10. Management of Obesity 11. Psychiatry and the Primary Care Physician 12. The Future of Community Psychiatry 13. Anxiety and its Management 14. Affective Disorder: Endogenous Depression or Manic Depressive Illness?

1984 £40.00 0 333 27281 1 340pp

THE HISTORY OF LITHIUM THERAPY

F. Neil Johnson

A fascinating and meticulously researched survey of the use of lithium in medicine. Includes previously unpublished photographs.

1984 £35.00 0 333 36942 4 216pp

PSYCHOLOGICAL INFLUENCES AND ILLNESS: HYPNOSIS AND MEDICINE

ed. David Waxman

Presents important new research on the use of hypnosis in the control of pain, in the treatment of tension states and muscle spasm, and in sexual problems and obstetrics.

Contributors: Ernest Hilgard, Basil Fine, Philip Oystragh, Karl Fuchs, Claud Lum and R P. Snaith.

Published in conjunction with The Royal Society of Medicine
1984 £20 00 0 333 34743 9 91pp

THE PSYCHOPHARMACOLOGY OF LITHIUM

F. Neil Johnson

The first complete review of all psychopharmacological data on the use of lithium to treat manic depression

1984 £50.00 0 333 36941 6 216pp

SCIENTIFIC STUDIES IN MENTAL RETARDATION

ed. John Dobbing, A. D. B. Clarke, D. J. Corbett, J. Hogg & R. O. Robinson

Brings together the original contributions, critiques and discussions of the First European Symposium on Scientific Studies in Mental Retardation.

1. Epidemiology and Preventive Aspects 2. Research into Biomedical Aspects 3. Cognitive & Linguistic Research 4. Research into Psychosocial & Service Aspects

Published in conjunction with The Royal Society of Medicine
1984 £59.00 0 333 35454 0 608pp

MOVEMENT DISORDERS – TREMOR

ed. Leslie J. Findley & Rudy Capildeo

The most comprehensive study of normal and pathological tremor currently available. Interdisciplinary in approach, it contains contributions from all the leading researchers in this field, including C. D Marsden, R. Young & K E. Hagbarth.

1984 £55.00 0 333 35040 5 512pp

Research and Innovation: A Record of the Wolfson Technological Projects Scheme 1968 - 1981.
By L. Rotherham.
Clarendon: 1984. Pp.99. £12.50, $18.95.
Foresight in Science: Picking the Winners. By John Irvine and Ben R. Martin.
Frances Pinter, London/Longwood, Dover, NH: 1984. Pp.166. £12.50, $21.

THOSE choosing the investments needed to generate technological developments with long lead times have at least three difficult fundamental realities to cope with.

First, the Top Nation (Spain four hundred years ago, France two hundred, Britain one hundred, the United States recently, Japan soon, perhaps China after that) has the easiest job; such a nation can afford to be involved in all important fields, and so does not have to face the politically awkward decisions about what *not* to do. Accordingly, its technology choices are concentrated on the more detailed matter of the picking and efficient prosecution of *project* winners. This is by no means easy, but it is an area where lobbying from those rejected is a little more manageable. Other, smaller economies have to contract out of some important topics because they cannot afford everything, and thus have to begin with criticism from the lobbyists for the items that lose out. This is true whether the rejection is explicit, courageous and rational, or whether it is left to the shorter-term working of the market process.

Secondly, there are two kinds of forecast necessary for these decisions, whether or not they are prepared explicitly. On the one hand, one needs to predict the general climate of social relevance and acceptance for possible new technologies. On the other hand, one has to foresee the relative positions and comparative advantages of different competitors, whether nations or sub-national institutions such as firms or research teams. For the first, one is predicting an environment over which one has little control; for the second, one is in the business of partly self-fulfilling prophecy. A team having cohesion and enthusiasm can, with a less attractive technology, sometimes prevail over another with better propositions but which is bedevilled by internal rivalries and inefficiencies. (This point is forcefully made by Irvine and Martin on p. 144 of their book, where they point out that self-fulfilling prophecy is an important component of Japanese success.) So the two parts of policymaking — trying to predict the weather, and deciding between umbrellas, parasols and other devices — must be to some extent separate.

Thirdly, in retrospect no forecast can be seen to have been absolutely right; even though one protagonist predicts so much better than everyone else that his nation or firm gains great comparative advantage, he will have been wrong in many conspicuous respects and practical success will usually be accompanied by unjust criticism of (often irrelevant) error. This is why the ambitious get into politics and stay out of explicit forecasting if they possibly can. "Act promptly, but never give your reasons; your actions may well be right, but your reasons will usually be wrong." "Treason doth never prosper; what's the reason? Why, if it prosper, none dare call it treason."

Against this background, it is not surprising that books on the conduct and success of forecasting in science and technology make melancholy reading, especially in those countries that once were Top Nation and are now no longer. Of the two books reviewed here, *Foresight in Science* (which should really have been called *Foresight in Technology*) is concerned with national technology policies and decision-making at the macro-level, and only incidentally covers the science that underpins them, while Dr Rotherham's book, *Research and Innovation*, is a record of the Wolfson Technological Projects Scheme which, between 1968 and 1981, allocated a total of £17 million to 186 projects — an average of just under £100,000 each. But, because such micro-decisions determine whether the bright people in universities languish unfunded, devote themselves entirely to intellectual curiosity, or seek to understand and link their work with social needs, the importance of the Wolfson scheme is greater than the size of the sums might suggest.

Many funds finance projects and study; the Wolfson initiative, master-minded by Lord Zuckerman, sought to break new ground by using money to launch teams that could thereafter earn their own living by trading in the technology that they generated. Grants were usually to be once-and-for-all, so that minds were to be concentrated by the prospect of being hanged. Thus, the assessors of the many applications were going much further than the normal process of peer judgement on scientific merit, and were attempting to forecast business success. By comparison with the rest of the academic funding system in Britain, the Wolfson scheme has had, *pro rata*, a good deal of impact on the economy at large. It must, however, be recognized that the Wolfson teams usually drew heavily on the results of work funded by the British Research Councils or University Grants Committee. Thus, Wolfson has sought to set up a series of do-it-yourself "Micro Research Development Corporations" alongside the National Research Development Corporation. The original objective was that each team should survive after the end of the grant by selling its efforts and wares in the market, and to generate capability for innovations rather than for measurement and more orthodox consultancy services. However, this objective has been broadened, for Wolfson has now endorsed as "success" two other kinds of team self-sufficiency.

One is that of those groups which, though not yet trading successfully in the market, have enhanced their thrust and esteem enough to win support from the Research Councils at the end of the Wolfson grant; the other is the achievement of the groups which have met quite new needs in measurement and technical consultancy. This point is illustrated by Dr Rotherham's thumbnail sketches of each of the projects funded, as well as his overall critique, which show that the total success rate of over 50% includes about 10–20% as "innovation contribution", about 20% as "contract measurement and consultancy" and about 20% funded after Wolfson from the public purse. These are impressive results, and we really need a more precise assessment along these lines. Dr Rotherham does not attempt it, and indeed is reflective and descriptive rather than judgemental, possibly on the reasonable ground that comparisons are divisive and that academic dog should try to avoid eating academic dog. His book is nonetheless a most useful quarry for information about the Wolfson units and ideas about adventurous funding methods.

Another comparison can be made between the numbers of awards to different institutions and of resultant commercial successes. Four universities were awarded around £1 million or more: Imperial College, Manchester, Southampton and Birmingham. Of these, Southampton has the biggest yield of market trading, but mainly in the assessment, advice and measurement business. It is, however, rather early to draw firm conclusions about improved methods for project choice. Perhaps it is not unexpected that the pattern of Wolfson esteem for different universities, as measured by grant levels, is very different from that of the University Grants Committee as shown by the pattern of the 1981 cuts in their funding.

Foresight in Science, which was written under contract to the UK Advisory Committee for Applied Research and Development (ACARD), is concerned almost entirely with the machinery used for technical forecasting in different countries, and the notice taken of such forecasts and agencies by the political masters. There is good

justification for the lack of attention the authors give to case detail in that there is fair unanimity in different countries' choice of the technological areas likely to be of most importance during the next few decades. Consequently, most interest lies in the extent to which the forecasts are used, taking national capabilities and disabilities into account in determining policy (if any) in this area.

On this basis, France and Germany emerge as confused and unimpressive; the United States pluralistic and somewhat wasteful; Japan mysterious, purposeful and effective; and the private sector everywhere assiduous but rather blinkered. The snag is that formal forecasting is always supplemented by unofficial, less transparent procedures. In France, for example, the polytechniciens do not seem to pay much attention to the machinery for science funding, and the key decisions — for example those concerning the reconstruction of the auto industry after the collapse of Citroen, the building of a common engine plant, the methods for ensuring the use of French computer equipment, and the early entry of France into microelectronic telephone switching through the system E10 — are not closely linked with the academic scientists and their work. The polytechniciens carefully watched the Colloque Nationale, and the grand Gallic gestures of M. Chevènement. They were then able to cash in on any beneficial trends when they were brought back to clear up the chaos.

In Germany, it seems to be the engineers rather than the scientists whose priorities have most effect on business decisions and are most responsive to them. Again, there are informal alliances which play a large part in German industrial technology but which are not part of official machinery. In the United States, public purchasing of prototypes and funding of private sector research through NASA and the Department of Defense moves very large sums of money in such a way as to lengthen the forward-looking of American firms. However, the policies of President Reagan, especially those currently designed to cut the budget deficit, are eroding energy and other technologies with long lead times. In all three countries, as well as Britain, strong internal rivalries and conflicts have diminished the extent to which choices, once made, are pursued loyally and single-mindedly. France, Germany, the United States and Britain have often failed to enter the recommended and important area of self-fulfilling prophecy.

It is in Japan that formal and informal processes operate hand-in-hand, thereby ensuring that decisions get the maximum chance to work; for example, the development of ceramic gas sensor systems has been helped by a law compelling every house to have a gas leak detector. Japanese weakness in primary, counter-cultural innovation is offset by the prompt identification of successful new ideas from other countries, and early inward licensing while it is cheap. Japanese technologists have surveyed the world, and brought foreign teams to Japan, to encourage competitiveness in their next round of computer and control-engineering development. Perhaps more important still, because of the large proportion of the gross national product that is invested, the Japanese banks are able to insist on long-term technical planning as a condition for loans. Although a very great deal happens that is not visible on the surface, the unity of purpose makes the visible moves a better guide to events and prospects than is the case elsewhere.

What will not be seen for a long time is whether the elaborate, dedicated and expensive Japanese effort being devoted to the science base will bear fruit, or whether social dedication to teamwork and co-operation will inhibit the idiosyncratic innovator. Real originality — the eccentric thinking of the counter-cultural heretic — is not understood or tolerated by a disciplined social machine such as that in Japan today.

Irvine and Martin's book is a valuable source of information on models and systems used in various countries, and how they are meant to work. Confusion, however, arises from their intermingling of attempts to generate policy for technology on the one hand, and science on the other. It is easier to identify technological priorities, and to plan accordingly, than to plan science. Irvine and Martin say clearly that market-pull and ideas-push are needed in collaboration, but the technology does not usually arise sequentially from science (despite the understandable belief to the contrary in the science community); usually, it uses science as a source of strength and reinforcement. Some science planning can be done in response to technological opportunity and need, but this must not exclude curiosity-orientated work, which formerly was cheap enough to be based on peer judgement of the promise of brilliant individuals. Unfortunately, the growing expense of some curiosity-based science is now creating a very awkward need to make choices on the basis of such difficult concepts as "number of major surprises per megabuck". This deeply passionate process must be kept separate from technological planning, or muddle ensues. □

Duncan Davies, formerly Chief Scientist and Engineer at the Department of Industry, and Research and Development General Manager of ICI, is a consultant and Chairman of the ceramic development company BCRA Ltd.

● Longman has recently published a collection of essays examining the implications for scientific endeavour of the increasing links between academic research and industry. The book is entitled *Science as a Commodity: Threats to the Open Community of Scholars.* The editors are Michael Gibbons and Bjorn Wittrock, price is £9.95 in paperback.

Mathematics and membranes

W.D. Stein

The Physical Chemistry of Membranes.
By M.E. Starzak.
Academic: 1984. Pp.334. $47, £38.
Equations of Membrane Biophysics.
By N. Lakshminarayanaiah.
Academic: 1984. Pp.426. $69, £55.50.

READERS of *Nature* will be aware of the present excitement in membrane biophysics. Our ability, by the patch-clamp techniques of Neher and Sakmann, to measure the electrical properties of single ionic channels in membranes means that the molecular events in channel opening and closing, and in ionic movement through channels, can be monitored. More and more ionic channels are being isolated biochemically, the genes coding for the channel proteins cloned and sequenced, and the channel proteins themselves investigated by physical techniques. Structural models of such channels have been proposed, and the theoretical investigation of ion movement through channels is at a stage where the electrical properties of channels will soon be predictable from them. The study of membrane carriers and pumps lags behind, but pumps have been crystallized in two-dimensional arrays, and the structure of a pump solved, albeit at a low resolution. The dynamics of the membranes themselves are beginning to be understood, the viscosities of regions of cell membranes measured, and the intra-membrane and trans-membrane diffusion of membrane components determined and understood in physicochemical terms.

All this is the meat of university courses on membrane biophysics. I know, however, from personal experience, how difficult it is to convey the sense of new excitement while still providing the firm basis of physical chemistry that students need for a critical appreciation of the modern approach. The subject is of its nature heavily mathematical and quantitative. What, then, is one to do with this mathematics? Write it all out on the blackboard — or merely refer the student to the original (often difficult) paper? Both of the books under review try to solve this problem by providing a text which includes many of the relevant equations. Unfortunately, neither book is really satisfactory.

Starzak's book suffers in part from its misleading title. One would expect that *The Physical Chemistry of Membranes* would treat the membrane's physical chemistry — the forces that mould and stabilize it, its viscosity, the diffusion within the membrane of phospholipids and proteins. These topics are not in fact covered, and the emphasis falls on the surface chemistry

of the membrane and on ion movement across it. The problem, it seems, is that Starzak has felt obliged to deal with a number of general questions of solution chemistry, elementary and irreversible thermodynamics, chemical and enzyme kinetics — even electronics! — on all of which topics excellent books are available at both elementary and advanced levels. Even the relevant topics that he does include, such as ion movements across excitable membranes, are well discussed, at the same level, in other texts. A further defect is the exceptionally poor bibliography. No attempt is made to refer the student to available texts on the subjects covered, and of the 30-odd papers quoted nearly half are citations (sometimes incorrect) of sources from which diagrams have been taken.

Lakshminarayanaiah's book is a more substantial effort. It is comprehensive in scope, covering most of what one would expect to find on ion transport across membranes, with treatment (more elementary) also of non-electrolyte flows. It is hard going in parts, especially where the meaning of a symbol alters over a few pages. I found the treatment of surface potentials quite opaque as these changed names (from distribution to outer voltage potentials, from Lange to contact or from inner to Galvani) and interchanged symbols (from Ψ to Φ to V). The bibliography again is unsatisfactory, being perfunctory and even irrelevant in the earlier chapters. But the main drawback of the book is its style. There are difficulties with the language itself — such as the absence of the definite article — and obscurities in the text from which it is inordinately difficult to wrestle meaning.

There was certainly a place in the literature for both of these books. However, in order successfully to fill this place they should, perhaps, have been more keenly criticized while still in manuscript. □

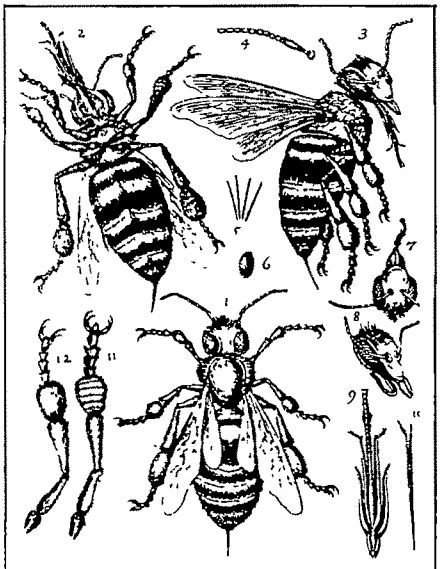
W.D. Stein is Professor of Biophysics at the Hebrew University, Jerusalem.

Vision interrupted

John Mollon

Visual Masking: An Integrative Approach.
By Bruno G. Breitmeyer.
Clarendon: 1984. Pp.454. £25, $34.95.

MAN's resolution in time is poor. If we are to analyse two successive stimuli separately, or if we are reliably to report their order, then the interval between them must exceed 50-100 milliseconds. Our modern machines have a much better resolution; and at least one specialized subsystem in the human brain — the subsystem that discriminates the directions of sounds — enjoys a temporal resolution that is almost four orders finer than that of the system as a whole.



The coarseness of our temporal resolution is well illustrated by "backward visual masking". If a target letter is presented for only one millisecond, it will be easily identified by a human observer, provided it is of sufficient contrast; but if it is followed within, say, 50 milliseconds by a spatially superimposed montage of letter fragments, then it will be masked. Especially curious is the form of masking called "metacontrast": if a bright square patch is presented briefly and is followed within 50 milliseconds by two flanking patches that are of the same luminance as the first patch, then our perception of the first patch is almost completely suppressed.

Such phenomena promise a means to analyse the early processes of visual perception; and therefore masking has been experimentally studied for over a century. There has not previously been a book on the subject, and so it is valuable to have Dr Breitmeyer's comprehensive survey.

Among the topics he covers are persistence of vision, masking by flash and by pattern, metacontrast, the effects of stimulation of the peripheral visual field, and the integration of information from successive fixations. One of Breitmeyer's strengths is his excellent grasp of the classical German literature on masking. He does, however, neglect the French literature, and particularly wanting is discussion of the papers of Jeanine Blanc-Garin. Nor is there any reference to Baylor and Hodgkin's work on vertebrate photoreceptors, a weird omission in a book concerned with the temporal aspects of vision.

Breitmeyer's skill lies in giving accurate short accounts of experiments and theories. However, he could have been more critical of many of the studies included. For example, he devotes several pages to an analysis by Michaels and Turvey that purports to show that the first and second of two stimuli contribute equally to the formation of a "cortical icon". The analysis depends on subtracting the masking curve for the non-dominant eye from that for the dominant eye; in each case, the ordinate is the percentage of trials on which the target is correctly identified and the abscissa is the temporal relationship of target and mask. The fallacy here is the common one of taking behavioural performance as a direct measure of some internal process or state. Breitmeyer unjustifiably assumes that the performance difference between, say, 100% and 60% correct corresponds to the same degree of internal integration as does the difference between 40% and 0%. (If this type of error had a recognized name, it might occur less often. "Fallacy of reification" would capture the essence of it.)

But worst of all, Breitmeyer is silent about an experimental scandal that has marred this field of research. Between 1965 and 1980, many experimenters (including Breitmeyer) uncritically used commercial tachistoscopes that had physical time constants much longer than manufacturers claimed. What happened was that the manufacturers — and those few experimenters who did bother to calibrate their tachistoscope lamps — used photocells sensitive to the fast, short-wave component of the lamp output whereas the eye was maximally sensitive to the slow, long-wave, lamp phosphor. The properties of commercial tachistoscopes were documented in 1978 (*Q. J. exp. Psychol.* **30**, 555) and it would have been good to see Breitmeyer assess the problem as he reviewed the literature. Since 1978, tachistocopes have been largely replaced by computer-driven displays. Astonishingly, however, the persistence of the long-wave component of display phosphors has led to a fresh generation of experimental artefacts. Thus Chapter 10 of the book places great weight on experiments on integration across saccades, but these results had been shown to be artefactual before the date of Breitmeyer's preface (see, for example, *Science* **222**, 188; 1983).

Nature magnified — enlarged views of the honey-bee, the earliest known studies made with the aid of a microscope, from Francesco Stelluti's Descrizzione dell'Ape *(1625). The illustration is reproduced from* Single Lens, *by Brian J. Ford, which will be reviewed in* Nature's *Spring Books issue on 25 April.*

Breitmeyer finally gives himself away in his long "Epilogue", a rambling, overblown piece of bull in which Aristotle, Galileo, Descartes, La Mettrie, Kant, Goethe, Santayana, Bergson, Monod, Tolman, Lorenz, Piaget, Polyani, Popper, Dawkins, Breitmeyer and others, jostle promiscuously. It is troubling that the publisher did not have the editorial firmness to delete this embarrassing 20-page essay. □

John Mollon is a Lecturer in Experimental Psychology at the University of Cambridge.

Good vibrations

Colin Gough

The Physics of the Violin.
By Lothar Cremer.
MIT Press:1985. Pp.450. $35, £41.95.

FOR over 150 years scientists have been investigating the physics of the violin. Some have been motivated by the hope of discovering the "Stradivarius Secret" — the scientific explanation of the highly-valued tone quality of many instruments of the famous Cremonese violin makers of the seventeenth and eighteenth centuries. For others, such as the author of this book, the attraction has been to understand the acoustical and vibrational physics that ancient luthiers empirically incorporated into their instrument designs, culminating in the "modern" violin around 1550.

In the nineteenth century, musical acoustics was at the forefront of science. People of the stature of Helmholtz and Rayleigh, often through their interest in acoustics, were laying the wave-mechanical foundation of modern physics. And in the early part of this century, Raman, later to win the Nobel prize for his work on optical spectroscopy, published his first scientific papers — on the physics of the violin. But thereafter, with the advent of the exciting new fields of quantum science, musical acoustics became something of a backwater.

In recent years, however, the subject has experienced something of a revival, arising partly from the recognition of a number of interesting problems of "classical" physics still to be solved, and partly because modern experimental and computational techniques now allow a much more realistic modelling of the science involved. Prominent in such activities have been Professor Cremer and his co-workers at the Institute of Acoustics in Berlin. Over the past 25 years, this group has published a succession of important papers on musical acoustics. Now Professor Cremer has summarized that work and has brought together material that was hitherto widely dispersed in the literature. Although no attempt has been made to provide a fully comprehensive coverage of current research, generous space is devoted to closely related work of other authors.

Cremer treats the violin simply as a mechanical structure that is forced into vibration by the bowed motion of the string. Almost half of the 450 pages are devoted to the bowed string problem, reflecting the author's main research interest. The transformation of vibrational energy by the supporting bridge, now widely recognized to be a major factor in determining the tone of an instrument, is discussed in detail, as are the vibrational modes of the instrument as a whole. This logical approach to the energy chain is concluded with a discussion of sound radiation and the way that this sound is modified by the environment.

Professor Cremer hopes his book will appeal not only to the scientist but also to the violinist or violin-maker wishing to understand the underlying science of their instrument. Unfortunately, few musicians or craftsmen are likely to possess the mathematical background to cope with the relatively sophisticated theoretical description of the complex vibrational characteristics of the violin. On the other hand, the book should certainly convince any scientific reader that musical acoustics, and the acoustics of the violin in particular, is a perfectly respectable and fascinating field of applied science; indeed recent research on the violin has led to a number of new ideas that could usefully be applied to many other vibrating systems.

Cremer makes no attempt to relate physical measurement to the subjective assessment of a violin's quality. As he explains in the preface, although modern science can provide a fairly accurate description of the physics involved in producing sound, we simply do not have the necessary language even to start to try and correlate them. This is a challenge which will probably keep physicists, psychoacousticians, players and instrument-makers busy for at least another 150 years.

Power and penguins

David J. Rose

A Guide to Nuclear Power Technology: A Resource for Decision Making.
By Frank J. Rahn *et al.*
Wiley: 1984. Pp.1,000. £101.30, $106.

NUCLEAR steam supply systems have millions of parts, far more than Boeing 747s and in their way just as high technology. Describing this technology in a single book, albeit a big one, is a daunting task— some might say impossible. But it is the subtitle, *A Resource for Decision Making*, that is the reason for my concern about this book, of which more anon.

What is there here, in 500,000 words of small print plus 900 figures and tables? In 20 chapters, from basic processes, through radiation, the fuel cycle, reactors, materials, operation, safety, health and environment, regulation, economics, proliferation and intermediate stops, the book describes a particular world of nuclear power, often in more detail than we want. It is mainly an American world, of diagrams, photographs and words about all these subjects. Not wholly, of course, because some topics such as hydrogen flammability limits and radioactive toxicities know no national boundary. But the Canadian CANDU reactor gets a mere eight pages, the British Advanced Gas Reactor four pages and the French reactor standardization one 10-word clause on page 799. Comment on the Far East, where many innovations are taking place, seems to be missing completely.

Even the great specificity about equipment and practices in the United States is not very well matched to the stated task of informing decision-makers. The book describes in great depth how things are now, somewhat mechanically: properties of steel, operation of the latches on a control rod drive, patterns of refuelling a light water reactor, an extractor evaporator for removing water from rod waste and a myriad of other things. Most of this, like the mythical book about penguins, gives the decision-maker more detail than he wants. It isn't wrong, but is it useful?

Decision-makers want to know other things. Why did the system work (or not) before? What are the present options? What are the trends? Compared to what? Here are a few examples.

- Why do nuclear power plants cost so much, when the entire nuclear steam supply system plus the turbine-generator costs only about 25% of the total? And why such large disparities from place to place? The chapter on economics lists increases in material costs, effect of lead time and so on, but still leaves a fuzzy impression.
- What about the prospect of substantially improved light water reactors for the near term? The work proceeds now, principally in Japan, aiming for higher capacity factor, less radiation exposure to workers, easier maintenance, more compatible materials and so forth. But I find nothing of this, only some four pages on such topics as the classic spectral shift idea. If decision-makers in the United States don't watch out, the initiative will pass from them, surely something they should know.
- The potential of smaller reactors is becoming an increasingly lively topic these days. Is there the possibility of overcoming the diseconomy of small size by the economies of serial, factory or modular construction? Such smaller reactors would decrease the financial exposure of electric utility companies. Again, there is nothing on the subject here.

Still, the book has its merits and can be useful, though not principally as a handbook for decision-making, let alone policy decisions or technology assessment. It is descriptive and not overly technical (as its preface says), and fairly well written. Of the twelve groups to whom the authors commend the book, two seem most likely to profit from it: engineers with an interest in but no special training in nuclear technology, and nuclear engineers wishing to get a broader grasp of certain aspects of nuclear technology. □

David J. Rose is Emeritus Professor in the Department of Nuclear Engineering at the Massachusetts Institute of Technology.

nature

NATURE VOL 314 18 APRIL 1985

Self-reliance means self-denial

The Indian government seems to be changing its policy on the import of technology. Far from undermining Indian hopes, this may be the best assurance that they will come true.

To what extent should developing countries seek to keep up with the industrialized countries of the world in technology? And how should they attempt to do so? Unhappily, there are many places in the world where the question is strictly academic. For most of Africa south of the Sahara, for example, the notion that indigenous science and technology might contribution to the solution of immediate problems is, for the time being, an impossible dream (which is not to say that it should be forgotten). But there are other states, of which India is the chief example, where governments have for decades sought to drag themselves into the future by devoting resources to research and development. Often, as a consequence, they have run into criticism from those elsewhere who complain that when resources are so scarce, they should be spent instead on more immediate tasks, the relief of poverty perhaps. That argument is mistaken (and patronizing as well), but that does not absolve developing countries from working out sensible policies on research and development.

The need is illustrated by the public row in India during the past month over the new government's policy on semiconductors. At budget-time last month (see *Nature* 4 April, p.496), the Indian government announced several measures to liberalize the import of technological equipment from overseas — computers, for example, and also announced an arrangement with the Hemlock Semiconductor Corporation of the United States under which the overseas company will build and license a polysilicon plant in India. This decision has aroused opposition within India from three sources — those parts of the Indian research establishment that complain that the deal demeans their work, industrial companies that consider the arrangement an unfair challenge which robs them of opportunity and those who argue more generally that dependence on overseas technology is inappropriate for a country such as India. The government's resolution of the argument, announced last week, is a compromise: the arrangement with Hemlock will go ahead, but the Mettur company, which has built a 2-tonne a year pilot plant for manufacturing polysilicon by a process developed at the Indian Institute of Science at Bangalore, is also to be encouraged to build a 25-tonne plant at Baroda. Meanwhile, according to the electronics minister, Mr Shivraj Patil, the indigenous technology will be further encouraged by the placing of research contracts with laboratories such as the National Chemical Laboratory at Puna. By what tests does it make sense to follow both paths, keeping a dog but being prepared to bark oneself, so to speak?

Self-reliance

The answer, convincing enough, is complicated, and turns on the distinction commonly made in India between self-reliance and self-sufficiency. Self-reliance is that state of grace in which a country embodies the technological skill needed to accomplish all known goals, whence the considerable Indian investment in space research. Self-sufficiency is more demanding, requiring not merely the skill but the capacity (technical and financial) to do everything. Since independence in 1947, Indian governments have been wedded to the doctrine of self-reliance, and have also flirted from time to time with that of self-sufficiency (whence, in part, the cumbersome system of import controls now being dismantled).

The doctrine of self-reliance is especially confused in its application. India's need, like that of other developing countries, is for a degree of technical competence that will suffice to meet the unknown demands of the future. One ingredient of any provision to this end must be institutions at which scientific work (teaching as well as research) of the highest quality is carried on. India is reasonably but not lavishly provided in this respect: there is a handful of fundamental research establishments of international standard, but the quality of training and research within the university system is too patchy to ensure that the fullest use is made of talent. More serious questions arise in the application of technology. Since the 1950s, India has maintained its large nuclear energy establishment for two declared reasons — to provide a model of the indigenous application of technology in a daunting field, and to maintain independent control of an industry whose importance ranks high, politically and economically. In the first respect, the policy has worked well: the Indian Atomic Energy Commission is an important source of technical expertise. But India would have had more rapid access to nuclear power if it had been able to sign contracts for building power stations with overseas suppliers and to put up with controls on the use made of plutonium. This is the lesson that Mr Rajiv Gandhi now seems to have applied in the smaller matter of the semiconductor industry.

Prudence

In prudence, he should now go a step further. A huge half-developed half-developing country such as India has two needs of technology — the chance to manufacture products that compete on world markets, thus earning the foreign exchange needed to pay for imports, and the promise that, in the future, there will be even more sophisticated things to make and sell, domestically and overseas. Traditionally, Indian governments have sacrificed the first need to the second. The notion that India might successfully build an industrial base by licensing technology from overseas, and only afterwards embellish that with its own distinctive contributions, has often given great offence. Yet this is how many other modern states have prospered. In India, a further benefit of a policy typified by the Hemlock deal would probably be that Indian technology would be improved in those respects in which it is at present weakest, the management of projects. Mr Gandhi's government should build on the precedent it has now established, looking for opportunities to benefit from technology now, not later Far from being a threat to what may lie distantly ahead, a policy of judicious exploitation of other people's technology is a necessary foundation for the launching of more ambitious enterprises in the future.

The bearing of the Indian problem on the condition of other developing countries is remote, but not entirely negligible. While the world wrings its hands over the famines sweeping much of Africa, it tends to be forgotten that the agricultural deficits that afflict them have been outlawed in India by the intelligent application of technology, that of agriculture. Experience not just in India but in the United States has shown that the improvement of food production requires not merely technical innovation (new seeds especially) but means by which farmers, often peasant farmers, can be helped to use them efficiently. Yet during the past twenty years, this combination of research and extension service has been eroded in many of the countries of West Africa

where it was once productive. Many other developing countries have never benefited in this way. The moral for them is that priority should be given to the development of agricultural research. The other leaf that should be taken from the Indian book is the demonstration of competence in the pursuit of science, if only so that too much talent is not lost too soon. □

Powell bites dust

The British government needs to think hard now about surrogacy.

THE British government has done the decent (and courageous) thing by deciding that it will not lift a finger to save Mr Enoch Powell's bill on *in vitro* fertilization from being lost in the procedural hazards of the House of Commons (see p. 573). Common sense requires that there should be an opportunity to consider carefully how research in this field should be regulated. That regulation of some kind is necessary is agreed by everybody, even those who work in laboratories, but there are serious doubts whether the 14-day limit suggested by the Warnock committee is either appropriate or workable. It is to be hoped that the government will now consider seriously whether regulation by public ethical committee would be preferable, not least as a way of meeting the public concern that research with living human embryos should be responsibly designed and soberly directed. That course will not comfort those (Mr Powell included) who hold that the whole idea is an abomination. That is the sense in which the government has shown courage — and is the reason why prudence again requires that it should press ahead with its own legislation as quickly as it can.

To take the edge off the complaints there will be when the Powell bill is defeated next month, the government plans that there will be an outright ban on what is called commercial surrogacy, the practice by which healthy women offer the service of gestation to others for a fee. Warnock would have banned all surrogacy, but an important minority opinion on the committee held that some allowance should be made for exceptional circumstances. The plain truth, now, is that nobody knows how common may be the practice in countries such as Britain, and there is only guesswork to suggest what may be the circumstances (apart from the infertility of the intended mother). Yet reports abound of women providing this service for infertile sisters, while there is no way of knowing what small proportion of illegitimate births followed by adoption are essentially surrogacy arrangements.

That is one reason why the outright ban on "commercial" surrogacy now proposed deserves more careful consideration. In the spirit of the present time, which rightly allows an adopted child to learn something about its natural parents at majority, frankness about genetic origins is in fashion (and could, sometimes, be medically important in tracking genetic defects). Should these principles not also apply to children born of surrogacy in the forms now accepted? Will such practices, tacitly condoned at present, become crimes if the surrogate mother is rewarded in kind, not cash? And what is to happen if the small but unavoidable risks of pregnancy to the mother should become realities? Do her dependants go neglected? These questions may be hypothetical, but they are also important.

The British government has started from the other end of the problem — the publicity and the attendant fuss following a surrogate birth last year in which a commercial agency had been involved. Would the fuss have been as great if the agency had been a registered charity, organized perhaps as if it were an adoption agency? Almost certainly not. This is but one reason why the British government should be prepared to allow for exceptions to the rule it is now planning to introduce. The guiding principles should be that surrogacy should not be allowed to make anybody's fortune but that women who volunteer to provide the service should be safeguarded and repaid for their time and trouble, preferably in a manner open to public scrutiny. Is that too much to ask? □

International manners

The US administration should not offend its friends overseas by tactlessness.

NEXT month's meeting of the heads of government of the major industrialized nations, to be held at Bonn in West Germany, has all the makings of a rough-house. On this occasion, the hard core of the agenda, economics, will be the chief reason why the United States will find itself pinned uncomfortably in a corner. But US policy on strategic arms is likely also to sour what people have to say to President Ronald Reagan. Continuing doubt over US intentions over its star wars plans is one bone of contention. Italian President Bettino Craxi was right to complain last week that the US administration owed Mr Mikhail Gorbachev a less ungracious reply to the Soviet offer to suspend the deployment of SS20 missiles aimed at Europe than the jaundiced comment that it was a mere propaganda ploy.

The substance of these issues has been much debated, here and elsewhere, but the manner in which the United States now conducts its international business is becoming an obstacle to its attainment of its objectives. Even those who agree with what the administration is trying to achieve must be dismayed. Mr Gorbachev, after all, declared that the Soviet Union would unilaterally halt the deployment of SS20 missiles within range of Western Europe until November, and would continue a moratorium thereafter if mutual agreement was reached by then. The proposal is full of snags, while the plan to make it public at this stage is a breach of the agreement between the superpowers to restrict their negotiations on strategic arms to the closed sessions at Geneva. But even a thoroughly sceptical administration could have contented itself with something like "High time!" or "There'll be time to talk about that at Geneva". Last week's needlessly hard lines will have made many third parties ask who are the bad guys now.

Much the same is true of the US administration's public statements on the international money problem. In the past few days, US cabinet officers have too quickly taken up President Reagan's cry last month that there would be no imbalance in the world economy if only European states were as productive as the United States, which is at best a half-truth and which may even be more false than true. (If Europe were as productive as it might be, the United States would not be able to fund its present deficit by borrowing from abroad except by pushing interest rates still higher.) The irony in this is that the United States seems not to have been restrained in its attempts to correct its trade balance with the most productive of its international competitors, Japan. But the proposal now being canvassed by officials in Washington that would-be US exporters should be represented on the regulatory committees that will deregulate the supply of equipment to the Japanese telephone system will seem especially demeaning in Japan, where it will be recognized that the proposal would be constitutionally impossible in many places, and in Europe, where it will be asked why only US exporters should enjoy this privilege.

Complaints such as these that the United States too often behaves as if its own interests are paramount are not new. Most people also acknowledge that the United States has a special role in world affairs, militarily and economically. The sympathetic among them also appreciate the difficulty of a government such as that of the United States, with huge domestic preoccupations and watched over by a necessarily parochial Congress, in finding forms of words to explain itself that do not raise hackles elsewhere. Yet the administration's performance seems to be getting worse.

Part of the trouble may be the number of new faces, or of old faces in new jobs, that have made their appearance at the White House and in US government agencies since the beginning of the year. That is the charitable explanation, in which case Bonn may be a stimulus for changing tack and for learning that international relations are as easily soured as personal relations by tactlessness. Let us hope the explanation is not more sinister. □

Research secrecy

Pentagon plays havoc at optical conference

Washington

THE US Department of Defense (DoD) caused severe disruption at a technical symposium of the Society of Photo-Optical Instrumentation Engineers (SPIE) in Virginia last week when it withdrew at a few days' notice some 50 papers previously scheduled for presentation. The titles of the papers and some of the abstracts had been cleared for publication by DoD, but many of the texts were later found to contain either classified information or information subject to export regulations.

Eventually, most of the papers were presented (after some censorship) in a new type of "export-controlled" session, attendance at which required US nationals to certify that they would keep technical information confidential and which required foreign nationals to be sponsored by their embassies. Twelve of the 50 papers were declared classified and were not presented.

DoD last year declared that it would rely only on classification to restrict publication of fundamental research carried out on university campuses. As universities do not generally carry out classified research on campus, this seemed like a guarantee not to interfere with academic work. But the papers restricted at the SPIE conference were based on research by private contractors receiving DoD funds in category 6.3, which covers research that is potentially militarily sensitive and classifiable. Research in category 6.3 is not generally considered to be "fundamental", but none of that affected at the SPIE conference had actually been classified. Private research contractors, in contrast to universities, do accept contract clauses requiring researchers to submit papers to DoD for prepublication scrutiny — effectively a licence for DoD to prevent dissemination of the information should it so choose.

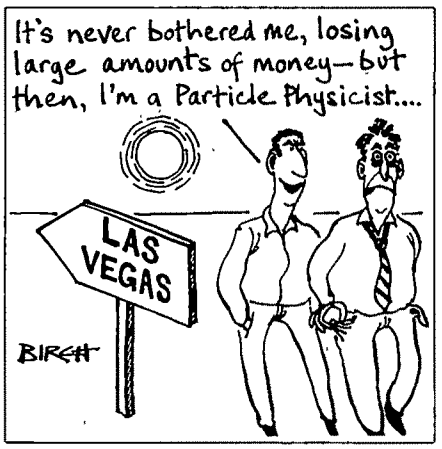
DoD says that all of the 50 affected papers would have had to be suppressed totally, by invoking prepublication review clauses, but for a new authority in the 1984 Defense Authorisation Act, under which DoD could allow most of the papers to be given, but on condition that those present would agree to the confidentiality requirements of export-controlled sessions.

Conference organizers say that no foreign national wanting to attend one of the two export-controlled sessions was denied access, but a number of them at the conference decided, for various reasons, not to seek admission to the controlled sessions, which dealt with synthetic aperture optics and wavefront sensors. Both areas have applications to astronomy as well as to weapons design: adaptive optics may be used to "untwinkle" stars in large telescopes, while synthetic aperture interferometry may allow many optical telescopes to be combined.

In the 1984 Defense Authorisation Act, DoD was given new authority to deny public access to unclassified technical data in its control that are judged to contain critical technology with military or space applications and which cannot be exported without restriction under Export Administrations Regulations. Previously, the department had no authority to withhold such technical information when faced with a request under the Freedom of Information Act.

It is now DoD policy to oppose the open distribution at conferences of unclassified technical data subject to export control. But DoD is also authorized to make such data available to those who are prepared to guarantee its confidentiality, which mechanism DoD brought into play for the first time at the SPIE conference. The exemption was granted by Congress in response to the concern of small defence contractors, which feared that they would otherwise be denied data necessary for them to bid competitively for DoD contracts.

The American Civil Liberties Union and the American Association for the Advancement of Science expressed concern last week that DoD had used a legal authority applying to DoD-controlled data to restrict public access to research material still the property of the contractors. DoD's explanation is that it still relies on contractual restraints to prevent open publication, and that only the exemption of those guaranteeing confidentiality was derived from the 1984 Authorisation Act. But, paradoxically, the exemption mechanism that DoD brought into play last week could in practice allow DoD to impose tighter control through contract mechanisms. Many allied countries fear that the United States is tempted to restrict foreign access to cutting-edge technology because of its commercial rather than its military importance.



Much of the very visible annoyance at last week's conference was due to the lateness of DoD's intervention. Sessions were being rearranged from one day to the next. But DoD says this was a practice run at making some export-controlled data available in unclassified but restricted sessions, and says that the lateness was due to the failure of another scheme which had been proposed — to have two entirely classified sessions running in parallel with the regular conference. Only one classified session was in fact held. **Tim Beardsley**

Accelerator scrutiny in prospect

Washington

THE US House of Representatives Science and Technology Committee has warned that it intends to treat particle physicists sceptically when considering construction of the proposed Superconducting Super Collider (SSC).

In approving the administration's request of $20 million for continued research and development on the accelerator project, much less than the $60 million that the Department of Energy (DoE) had asked for, the committee said that it doubted whether DoE's goal of starting construction by 1988 could be met.

Still smarting over its experience with ISABELLE, Brookhaven National Laboratory's $200 million fiasco, the committee said it would not even consider a proposal for SSC until DoE could prove that the superconducting magnets will function as planned for the advertised price. ISABELLE, delayed for years, was abandoned in 1983 after unexpected problems in design of the superconducting magnets. Although the problems were eventually ironed out, events in physics had in the meanwhile made ISABELLE obsolete, but not before a 2¼-mile-long tunnel, control room, experimental areas and magnet production facilities had been built.

Optimistic projections put the cost of the SSC magnets at 15 per cent less per unit of length than those now operating at Fermilab; at $5,000 per metre and assuming an 80-km ring, that works out at $400 million for the magnets alone. The current estimate for the total cost of SSC is still $3,000 million, not including detectors, research and development and allowance for inflation.

Leon Lederman, director of Fermilab, said that previous proposals had been approved by congressional committees almost "by return mail". "We're bearing the cross of ISABELLE", he said.

Stephen Budiansky

French geoscience

New umbrella wins friends

FRENCH oceanographers, geophysicists, geologists, astronomers and space scientists have clubbed together to form a new organization, INSU, the Institut National des Sciences de l'Univers, which will manage big research programmes under the financial guidance of the principal French research council for basic science, CNRS (Centre National de la Recherche Scientifique). INSU should give academic oceanographers, at least, more weight than hitherto in French science politics.

The institute has been created only after a fight from geophysicists. INSU is based on its predecessor INAG (l'Institut National d'Astronomie et de Géophysique), where the small but effective French community of geophysicists played a strong role. INSU, to their chagrin, includes the more traditional field geologists who outnumber the geophysicists more than ten to one. Some geophysicists, who see themselves as the vanguard of French geoscience, have strongly resisted the move. The struggle continues in the universities and in the laboratories of CNRS, where geophysicists argue that geologists should relinquish more of their posts to the "new geology".

Within INSU (which will be directed by meteorologist André Berroir of the Ecole Polytechnique), realism prevails, and the talk is of new big programmes that will unite the warring tribes along the lines of the recent survey of Tibetan geology and geodynamics headed by Claude Allègre of the Institut de la Physique du Globe. Possible programmes for 1986 include a study of Caribbean tectonics and work in Latin America on the Cordillera.

Geologists themselves will also benefit from the creation in INSU of a working group on medium-scale computers for the earth sciences. Undersupplied with computers, as are many French scientists, geologists expect to need powerful minicomputers to process image data from SPOT-1, a new-generation French Earth observation satellite to be launched later this year. Both science minister Hubert Curien and Berroir, the INSU director, are in favour, even if that means using foreign machines. (Berroir masterminded the first French purchase of a non-military Cray-1.)

Oceanographers feel that the institute will strengthen academic science. In France, the field has been long dominated by the technological interests of CNEXO (recently transformed into IFREMER, the Institut Français pour l'Exploitation de la Mer, by the addition of fisheries research.) INSU should provide oceanographers with some political power, authority and even money with which to strengthen the pursuit of basic science in the face of IFREMER's largely applied bias. Hitherto, they have had to rely on a small understaffed interdisciplinary programme of the CNRS, the "PIROCEAN" programme.

PIROCEAN, with its FF 10 million (£1 million) budget, will now be absorbed into INSU, where it will add to the FF 35 million (£3.5 million) brought by INAG and undoubtedly gain greater influence than it had when directly under the CNRS umbrella.

The new merger should also comfort CNEXO oceanographers whose 450 technical research staff were in danger of being swamped by the 600-700 scientists of the fisheries research organization in the earlier IFREMER merger. (That union also squeezed the research budget of both organizations, as salaries of the old fisheries organization were raised to match CNEXO's without a corresponding increase in total funds.)

Astronomers, meanwhile, who looked to INAG to support observatories and new telescopes, remain blissfully unconcerned. (French membership of the European Southern Observatory is paid for by the foreign ministry.) Plans are afoot for THEMIS, a high spatial resolution polarizing solar telescope for Tenerife (in collaboration with the British, Sweden, Denmark, Spain and West Germany) and for the completion of the millimetre-wave interferometer IRAM in the south of France (due to operate as an interferometer some time in 1987). But this year will be the first for which the astronomers (and geophysicists) have had to fight for large programme funds with geologists and oceanographers. The financial effects of the INSU merger will not be clear until the budget for 1986, due this autumn.

Robert Walgate

UK biotechnology

Public lab. makes private deal

ONE of the most unusual arrangements yet for turning public investment in research into industrial channels, Porton International, announced last week an arrangement with the British government that gives it the right of first refusal on biotechnology innovations at the Centre for Applied Microbiology and Research (CAMR), the laboratory at Porton Down in Wiltshire where British research in biological warfare was once carried out, but which was transferred to the Public Health Laboratory Service seven years ago. The same stretch of Wiltshire down remains the site of the Chemical Defence Research Establishment, operated by the Ministry of Defence.

The new arrangement is the outcome of several years of negotiation, most recently a process in which other major British companies had been asked to express an interest. Porton International already has agreements with CAMR for the exploitation of two of its proprietary developments, asparaginase (used in cancer chemotherapy) and a vaccine for herpes simplex virus (based on developments at the University of Birmingham as well as at CAMR).

In a joint statement, the company and the Public Health Laboratory Services Board said that the new arrangement will run for thirteen years from 1 April, and that the arrangement might be continued thereafter if neither party saw fit to pull out. A spokesman for Porton International said that developments not taken up by the company would remain the property of CAMR, and might be offered to other companies. But he suggested that such happenings would be few and far between.

The management of the laboratory will remain the independent responsibility of the director, Dr Peter Sutton, the Public Health Laboratory Service and ultimately the Department of Health and Social Services. But the existence of the new agreement is likely to divert the scientific interests of many members of the laboratory into directions that may be profitably exploited.

The agreement covers not merely biological materials produced by innovative methods but also new processes that may emerge (as for the manufacturer of phenylalanine and the intra-conversion of steroids). Apart from the materials already being brought to the market, there are plans for the production of frozen cell pastes (for the derivation of restriction enzymes), the production of enzymes (such as carboxypeptidases), vaccines other than herpes simplex (such as against pertussis virus) and cloned human hormones (such as human thyroid and follicle-stimulating hormones).

Under arrangements established before 1 April, Porton International is already financing the work of several members of CAMR. Nobody is as yet prepared to guess how large a proportion of the total cost of running the laboratory will derive from royalties provided by the company on sales of proprietary products. But a spokesman for the company guessed that more than half the 250 members of staff at CAMR were working on projects with some commercial interest, but that the laboratory's basic research was also essential to the success of the new arrangement.

Porton International Ltd is for the time being a holding company, with a number of subsidiaries (such as LH Fermentation) active in fields related to biotechnology. The recent development appears to have been financed by capital contributions from a number of financial institutions, including the pensions funds of several public companies and a number of insurance companies. The chairman of Porton International is Wensley Haydon-Baillie. □

Israeli science

Optimism from new minister

Rehovot

ISRAEL'S new science minister, Mr Gideon Patt, has a great many plans but very little money with which to carry them out. Nevertheless, he remains optimistic.

"As minister of commerce and industry", he declares, "I helped promote applied research. Now, as minister of science, I hope to boost basic research. And just as I initiated a five-year plan for industrial development in my old post, I now intend to initiate such a plan for the development of science and technology".

Patt points out that Israeli investment in science and technology now stands at 2.2 per cent of the country's gross national product (GNP), which is, as he puts it, "a respectable figure", and more than is invested, for example, by the Netherlands. But he hastens to add that the percentage figure is misleading on two counts. First of all, Israel's whole GNP is not large and so the total annual investment in research and development is around US$700 million, less, that is, than is spent on research and development by some individual US companies. Moreover, more than half of the available funds go to military research and development, from which the economy benefits to only a limited extent.

In spite of the problems in regard to applied research, Patt is far more concerned with the decline in funds available for basic research. He notes that the universities, where almost all basic research takes place, once allocated some 50 per cent of the funds for education and the other 50 per cent for research. In the past five years, however, because of massive cuts in government support, they have greatly reduced the money they allocate for research.

"Thanks to superhuman efforts by our scientists", Patt says, "we have not so far fallen behind. However, sheer devotion and ingenuity cannot make up for the lack of funds indefinitely and if something isn't done soon to remedy the situation, Israel will become a scientific backwater, just another little country with enormous problems and few resources with which to solve them."

Patt's solution, one already on the stocks, is to create a special $250 million fund from overseas sources for scientific research in Israel. This will yield up to $30 million a year to support research, a sum that will be supplemented by another $10 million from Israeli government and binational sources.

Why is Patt, a non-scientist, interested in basic research? "I'm not", he says, "I simply realize that without basic research, there will be no innovative applied research, no original products. And if we just base our industry on secondhand research, we will never be able to keep up with our competitors."

The science minister is certain that proper support for research will pay off, generating enough income, through new products, to repay investors in his special fund and to strengthen the economy.

Ultimately Patt would like to see his ministry of science turned into a ministry of science and technology. This would, he believes, facilitate the kind of overall planning that does not exist at present. More specifically, the chief scientists now found in most ministries, where they are charged with helping to find science-based solutions to ministerial problems, would be linked directly to the ministry of science and technology and would be guided by the overall goals that it sets.

In the meantime, Patt has already taken a first step towards greater coordination by creating a regular forum where all the chief scientists meet under his chairmanship at regular intervals. He is now planning to expand the scope of this forum by inviting university vice-presidents for research and development to participate.

Patt has also turned his attention to the shortage of trained engineers for Israeli industry, which already needs 2,000 more than it can find. He supports attempts to bring back some of those now in the United States, though he sees this, at best, as a partial solution. He has therefore joined hands with the army and with the manufacturers' association to establish a special school where practical engineers with two years of post-secondary training could be turned into qualified engineers in two years. But this school may never be created because the universities have tentatively reversed their long-standing opposition to such a scheme and will probably inaugurate a similar programme themselves.

But the new science minister sees real significance in his present position. "Ten years ago", Patt declares, "the ministry of science wasn't very important. Today it is already important. Ten years from now — if the country develops as it should — this ministry will be among the most important in the government." **Nechemia Meyers**

US telescopes

Caltech takes Texan wind

Washington

PLANNERS of new ground-based optical telescopes in the United States have been given pause for thought since the announcement in January from the California Institute of Technology of plans to build a 10-metre segmented-mirror instrument on Mauna Kea in Hawaii. The Caltech telescope, for which $70 million has been pledged by the William M. Keck Foundation, will be the largest optical telescope in the world. Fund-raising for other telescopes is likely to be harder as a result, and some plans may have to be rethought.

The Association of Universities for Research in Astronomy Inc. is doing preliminary design work for the National New Technology Telescope (NNTT), an instrument with four 7.5-metre mirrors that would be built by the National Science Foundation (NSF). But it will be difficult to persuade NSF and the Congress to vote $150–$200 million of federal funds for NNTT unless it offers US astronomers facilities that are clearly superior to those available elsewhere.

As things stand, NNTT would have twice the light-collecting power and 1.5–2 times the angular resolution of the Keck telescope. The question of whether that factor of two is sufficient to justify spending money on NNTT has yet to be decided, according to Laura Bautz, director of the division of astronomical sciences at NSF, who is forming a committee to examine the questions raised. Caltech is preparing a site for a second 10-metre telescope alongside the Keck telescope which, if it were built, might be combined with the Keck telescope for optical interferometry; such a combined facility would have characteristics roughly similar to those of NNTT.

Other telescopes have also been put into the shade by the Keck bequest. The University of Texas has, since 1979, been planning a 7-metre single-mirror telescope at its McDonald Observatory in west Texas, but has so far failed to raise the $50 million needed. The Texas state legislature, which is in the throes of a spending crisis, recently turned down a second request for $5 million of state funds to purchase the primary mirror for the telescope.

The publicity surrounding the Keck bequest will "undoubtedly make it harder" to find a private foundation willing to support construction of the Texas telescope, according to Harlan Smith, director of the McDonald Observatory. The telescope can no longer tempt potential sponsors with the glory of supporting the biggest telescope in the world (although Dr Smith points out it would still be the largest monolithic mirror telescope). Dr Smith argues that the supply of optical telescopes is not comparable with the supply of accelerators for high-energy physics, where there is continual pressure for ever-higher energies; rather, the pressure on optical telescopes is for observing time.

Even the Texans' claim to be building the world's biggest monolithic mirror telescope may shortly be disproved, however. The University of Arizona is expected shortly to announce a partnership with other institutions to build a 7–8 metre monolithic mirror telescope, and the Mount Wilson Observatory in California hopes for a similar instrument. **Tim Beardsley**

IVF

Australian export service

Canberra

THE *in vitro* fertilization (IVF) technology that produced that first freeze-thaw embryo and donor-embryo babies will soon become commercially available to infertile couples in the United States. The vice-chancellor of Monash University in the state of Victoria announced in Melbourne last week that an agreement had been reached, after 18 months of discussion, to form a private company to establish clinics, train US doctors and make available the techniques developed at the Queen Victoria Medical Centre by Professor Carl Wood, Dr Alan Trounson and their colleagues.

The company will be called IVF Australia (IVFA) and its first clinic is expected to be set up in New York. In the absence of more stringent local laws controlling IVF, the services on offer will conform with the guidelines set out in the Infertility (Medical Procedures) Act (1984), which will be proclaimed by the Victorian State Parliament in the current session, having been deferred early last year when state opposition parties successfully blocked its passage.

The bill specifically forbids surrogate embryo transfer and the embryo flushing procedure known as lavage (or *in vivo* fertilization), where fertilization is carried out in the womb of one woman and the resulting embryo flushed out and transferred to the womb of another woman. To achieve bipartisan support, the Victorian Labor government was also obliged to deny IVF treatment to couples in a stable *de facto* relationship, except those already embarked on the Monash programme before the act comes into force. This appears to rule out all US *de facto* couples as well as single women.

With more than 200 babies born at a time when most US clinics are closing down, the Melbourne researchers have brought several procedures to a high rate of success. The services offered will initially involve husband-and-wife gametes only, but will probably be extended to donor procedures as well, and will include embryo freezing and storage.

The Victorian legislation is based principally on the recommendations of the Waller committee, set up to consider the ethical and legal issues raised by *in vitro* fertilization (see *Nature* **311**, 288; 1984). The act bans any form of cloning and any p cedures where human gametes are mi with those of an animal. A couple may minate a (willing) donor, the wom sister for example, but no donor r receive payment beyond normal expen

The Waller committee recommen that research on embryos should ext only over the first 14 days. The Victo government has not yet formulated a reply to the committee's recommendati but the draft legislation provides fo Standing Review and Advisory Commi to be created to consider requests for proval of research with embryos.

Where does the act leave the frozen F embryos (see *Nature* **309**, 738; 1984), wh biological parents perished in an air cr leaving no instructions for their ultim disposition? According to the dr Victorian legislation as it now stands, embryos would be made available to ot couples on the IVF programme who wc be told that the embryos are unlikely grow to maturity because the methods u to freeze them were not as well develo as those now available. The prospec social parents would be supplied with n identifying information about the bi gical parents (the Rios) and if a per grown from one of the Rios embryos w to seek this information from the Victo State Health Commission, it would alsc non-identifying, subject to the discretio the minister.

No development or discovery will be corporated as part of IVFA's program until approved by a Bioethics Commi which, in the manner of the Wa committee and the Standing Review Advisory Committee, is likely to consis lawyers, philosophers, social workers medical researchers. The company will for the time being have its own research development function; the Monash Uni sity team, however, will continue to p lish its research results. Where patenta discoveries emerge, care will be taker enable proprietary rights to be secured l under the agreement, patenting of med procedures will not be permitted. The u versity has no equity in the company will receive royalties. Members of the l team in Melbourne will remain employ of the university and may receive paym on a consulting basis.

Professor Wood says that the money research generated by the royalty paym has become necessary to keep the team gether, given the low support accorde the IVF programme in the past; ethical jections to profit derived from the vanced techniques would, if taken appear to apply to all private medic There could be no absolute guarantee says, that a US doctor trained in the r techniques would not start his own cl offering procedures illegal in Victoria, such a clinic would then not continue to joy support from the Melbourne IVF te and a personal vetting scheme would help to minimize this risk. **Jeffrey Se**

Hetero-solid growth

UK seeks to catch up

A MULTI-MILLION pound stimulus to British research in "low dimensional structures" over the next five years has been announced by the Science and Engineering Research Council (SERC). The programme is intended to enhance the United Kingdom's ability to compete scientifically and, in the longer term, industrially in the field of heterojunction semiconductors, and the new physics associated with such devices. SERC has already allocated £3.5 million to the scheme, which forms a part of the strategy for "core science" heralded by the council's Science Board last year (see *Nature* **309**, 388; 1984).

Interest in low-dimensional structures has burgeoned over the past few years with the realization that they offer unprecedented opportunities for the study of semiconductor physics. In particular, the techniques of molecular beam epitaxy (MBE) and metal organic chemical vapour deposition (MOCVD) permit the construction of interleaved layers of semiconductor materials of precisely determined thickness — in many cases, only a few angstroms. In a superlattice, for example, layers of GaAs may alternate with GaAlAs. The difference between the two materials in their respective energy gaps separating the valence and conduction bands can result in a two-dimensional layer of highly mobile electrons. The physics of such layers, in which unique phenomena such as fractional quantum effects and phase transitions have been observed, is one of the most active research areas, while the potential industrial spin-off with, for example, high-speed devices and optical communications and logic is vast.

To a considerable extent, British researchers have, until recently, had to confine their studies to "off the shelf" materials supplied by companies such as GEC, Philips and Plessey. As a result of the new initiative, however, university centres for material growth are being established, allowing researchers not only to design and grow materials as dictated by their research but also to study and improve the growth techniques themselves. For instance, a group at the University of Cambridge, with the collaboration of GEC and British Telecom, is developing *in situ* electron lithography during growth by MBE.

MBE work will also be carried out at the University of Nottingham and Imperial College, London, while an MOCVD facility is being developed at Oxford. A typical cost for the establishment of an MBE or MOCVD facility is anything up to £500,000. Industrial collaboration will involve part-sponsored studentships and funding of cooperative research grants. In such schemes, the company involved generally has right of first refusal of patentable discoveries, proceeds being shared with the public purse through the British Technology Group.

NIH research grants

Multi-year grants on ice

Washington

THE Reagan administration's Office of Management and Budget (OMB) has struck a compromise with leaders of the Republican-controlled Senate over the number of new research grants to be awarded by the National Institutes of Health (NIH). According to the agreement, the number of such grants awarded each year would settle at around 5,500, 10 per cent above the current level but considerably below the 6,500 foreseen last year by Congress.

The agreement, if accepted on the floor of the House of Representatives and of the Senate, might defuse the confrontation with the White House over OMB's scheme to circumvent the wishes of Congress by instructing NIH to hold back $200 million of the $938 million that had been intended for this year's grants (see *Nature* **313**, 377; 1985). The issue of NIH grants remains controversial in Congress, however, and the agreement of both houses is by no means assured.

Congress, ever-generous to NIH, last year voted it a large budget increase and urged increasing the number of new and competing research grants awarded each year from 5,000 to 6,500. Because grants last typically for three years, however, Congress's action would have meant further large increases for the NIH budget in 1986 and 1987. OMB, seeking to reduce the federal budget deficit, told NIH to disregard the new grant figures suggested by Congress and to hold the number steady at 5,000; the $200 million left over as a result should be used to support second- and third-year grant continuations in 1986 and 1987.

The legal basis for OMB's action was questioned last month by the US Comptroller General, who was responding to a query by Senator Lowell Weicker. The Comptroller General's opinion was that the executive branch was not legally obliged to follow the wishes expressed in congressional appropriation committee reports about the number of grants NIH should support; on the other hand, OMB's specific plan, to fund 646 multi-year grants with the 1985 appropriation, was found to be illegal.

The administration has challenged the Comptroller General's opinion, and in the meantime the $200 million in question is being held in reserve: the matter has been referred to the Justice Department for a second opinion. As a compromise, the administration has undertaken that NIH should not commit funds to any multi-year grants before 1 July, by which time the question of legality will presumably have been sorted out.

Last week's agreement with Republican leaders refers formally only to fiscal year 1986 and beyond; it does not address the problem of what to do about this year's appropriation. It is thought likely, however, that the same figure of 5,500 new grants might be an acceptable compromise for this year as well. The administration would nevertheless still like to establish the legality of multi-year funding, despite certain opposition from Congress. Should legal obstacles prevent this, all the $200 million now being held back would have to be spent this year. One possibility being explored is that it might be used for a one-time-only extension of grants that narrowly failed to be extended this year: this would placate many disappointed researchers without incurring the commitment of a new three-year grant. **Tim Beardsley**

UK embryo research

Government stops Powell bill

The British government has now decided effectively to block the Unborn Children (Protection) Bill in its passage through the final stages of procedure in the House of Commons. The bill, which seeks to prevent the use of *in vitro* fertilized embryos for purposes other than to bring to term a particular fetus, was introduced by Mr Enoch Powell, MP, and received a large majority (127) at its second reading (see *Nature* 21 February, p.618). On 3 May, when the bill is due to be referred back to the House of Commons from committee, the government has decided not to provide enough time for debate, so that the bill's opponents will be able to talk it out. This decision has infuriated supporters of Mr Powell's bill, who argue that it should receive government backing because of the large percentage of MPs in favour of it.

A Marplan opinion poll published in Britain this week, however, reveals that 32 per cent of adults are in favour of embryo research, 41 per cent are against and 27 per cent "don't know". Nearly half of the opponents changed their minds when asked if they would favour research if it would help to eliminate genetic diseases, resulting in a total of 51 per cent in favour of research.

The government plans to introduce its own legislation, possibly in the parliamentary session beginning next October, based on the findings of the Warnock committee (see *Nature* **312**, 389; 1984). This legislation will be more comprehensive than Mr Powell's bill; Mr Norman Fowler, Secretary of State for Social Services, is pledged to prevent commercial surrogacy agencies of any kind from operating in Britain, and this will be included in the government's plans. **Maxine Clarke**

Algal structures

FIXED algae have been used for many purposes, but rarely for making what the French sculptor Ernest Pignon-Ernest calls "arbrorigènes". This pun on the French words for "tree" (arbre) and "aborigine" describes a collection of life-sized models carved out of polystyrene and containing fixed *Porphyridium cruentum*, a reddish single-celled alga that gives the polystyrene flesh tones. Pignon-Ernest's models now adorn the trees of the Paris Jardin des Plantes. The sculptor is fascinated by the idea that these sculptures need water and light.

Pignon-Ernest is not a scientist. He conceived the idea of using fixed algae, however, and approached biotechnologist Daniel Thomas of the University of Compiègne and his colleagues Claude Gudin of the solar biotechnology laboratory at Cadarache for ideas. Thomas, who specializes in cell and enzyme-fixing, had the technology of fixing P. *cruentum* (a common garden species) in polystyrene, and Gudin has been using it to produce polysaccharides using solar energy. (When its environment dries, the organism protects itself by secreting a sugary shell.) Pignon-Ernest found the material ideal, and the "breathing" arbrorigènes were the result.

Thomas, meanwhile, was also at work with another artist, Monet — or at least with his enormous "water-lilies", a 186 sq. m. canvas hanging in the Louvre gallery in Paris. This painting was damaged when it was first transported. Paper was glued to the surface of the paint to protect it, but the wrong glue was used and the picture remained misted and in danger of denaturing by interaction of glue and paint. Thomas came to the rescue, discovered the glue was starch-based and dissolved it off with enzymes. Which proves that biotechnology has its uses, even if those uses will have little effect on share prices....

Robert Walgate

Name for AIDS virus

SIR — Although I personally believe that the virus associated with acquired immune deficiency syndrome (AIDS), HTLV/LAV, has enough structural and functional similarities with the other human T-lymphotropic viruses (HTLV-I and HTLV-II) to justify its classification within the same family[1], I also recognize that more than just science and logic are at stake over the recent nomenclature debate[2]. If a more non-partisan name is ultimately called for, my personal suggestion is that the virus should be called human AIDS/lymphotropic virus (HALV). Human, because in the tradition of naming retroviruses, the species name is given; AIDS, because although it is not the only disease this virus causes, it is the one that gives it notoriety; lymphotropic, because this is the most basic and neutral characteristic of the virus. Since it looks enough like HTLV, and contains all three letters of LAV, it may well be the perfect solution for the two groups to meet *halv* way.

Aid for Chile

SIR — As you probably know, we in Chile are at present in great distress. On the evening of 3 March, Santiago suffered a catastrophic earthquake. An international campaign has already started, mainly to solve the immediate needs of the several hundred thousands of homeless people. The building of our physics department, although still standing, was severely damaged, most probably beyond repair.

Science in general and physics in particular are vulnerable in developing countries and clearly more so in situations like the present one. We scientists are often looked upon with suspicion and we cannot at present expect any significant help from the authorities.

Nevertheless, we have not lost our optimism and desire to carry on with our work. After assessing the real effects of the earthquake on our building we have decided to start a campaign to raise funds in order to build up a new one. We estimate that the basic need of the thirty physicists in our department could be met by a twenty thousand square foot construction.

We would welcome any material help or advice that our colleagues in the scientific community can offer.

LINCOYÁN GONZÁLEZ
Physics Department, University of Chile, Casilla 5487, Santiago, Chile

Embryo research

SIR — I am disgusted with your call for research ideas on human embryos (*Nature* 7 March, p.11). Any researcher participating in it (and those experimenting on human tissue obtained at abortions) should be forced to read Trevor-Roper's book review "Seas of unreason" (*Nature* **313**, 407; 1985).

The primary objective for any physician has to be care for the individual patient. We must not sacrifice human individuals for a potential benefit to others. Just as we do not kill AIDS patients to prevent the infection of others, experimentation with and killing of embryos and fetuses cannot be justified by potentially interesting research results. A statement of what those benefits might be is therefore irrelevant.

If human societies ever become aware again of those hippocratic truths, many of today's researchers will be judged then as are Third Reich doctors today. And we will ask disgustedly again, in the words of Trevor-Roper: "How could a civilized nation, in the twentieth century, not only permit it but actually cooperate in it?".

CHRISTOPH BODE
Massachusetts General Hospital, Boston, Massachusetts, 02114, USA

SIR — I read the News and Views article on human embryo experimentation (*Nature* 7 March, p.11) with incredulity.

Those of us who are not wholly in agreement with Enoch Powell's bill may believe that there are circumstances in which extreme necessity may make experiments of this type allowable. But your anonymous columnist is inviting scientists to *invent* research to do upon embryos: to dream up ideas, which might not otherwise have occurred to them, for research projects which would not otherwise have taken place.

Surely the ethical dubiousness of this incitement to experiment can only strengthen public opposition to all such experiments?

R.J. BIRD
50 Highbury, Jesmond, Newcastle upon Tyne NE2 3EA, UK

Suitable treatment

SIR — In a recent leading article about the unauthorized implant of an artificial heart, *Nature* describes the stereotypes being impressed upon the surgeon and the Food and Drug Administration (FDA) as the rugged individualist and the pin-headed bureaucrat. In the same vein *Nature*'s role could be described as the aloof and bloodless intellectual. Stripped of its urbanity, what your editorial really said was: let the patient die. *Nature* admits the implant functioned, and that the proper role for future implants may indeed be to stabilize patients awaiting appropriate transplants. Your objections to its use are very thin.

The issue of informed consent seems to me to be very artificial. Informed consent had been obtained in advance for a very aggressive procedure, a transplant. Do you really feel that even in the calm period before the surgery the patient and family would have objected to the possible use of an artificial heart on a temporary basis? The issue of FDA approval would seem very abstract and irrelevant to a family who felt that the implant had a good chance of working for the short time required.

The issue of use of a non-approved device should be put into perspective. Use of drugs for purposes not approved by the FDA is common practice in the United States. A good example is xylocaine, which is approved only as an anaesthetic, but has proved very valuable in controlling certain cardiac arrhythmias. It has been used effectively and apparently safely in that mode all over the country, and no one has said a word. Physicians use it, in some cases, because it saves patients who might otherwise die. Artifical hearts have captured the public imagination and so have engendered intense scrutiny of their use. The issues are no different from those dealt with in a more flexible way every day.

The idea that the surgical team could have been prepared with an authorized back-up is ludicrous. The cost would be astronomical, and the personnel and time are not there. The fact is that FDA has authorized a procedure, the transplant, without the possibility of the implant back-up that may be needed. Placed in this impossible situation different surgeons will react in different ways. I would prefer my surgeon to be the rugged individualist not dominated by the pin-headed bureacrat. *Nature*'s aloofness, either at the bedside or funeral, would not be welcome.

EATON E. LATTMAN
The Johns Hopkins University, Department of Biophysics, School of Medicine, Baltimore, Maryland 21205, USA

Dinosaurs did well

SIR — I am a layman, but I am tired of hearing about "theories" (really mere conjectures, as they cannot be tested) of the extinction of the dinosaurs.

They ruled the roost for a hundred million years, ample time for the opposition to get its act together, for the evolution of small, elusive animals that destroyed vegetation and ate the dinosaurs' eggs so that they died of hunger faster than they could reproduce.

They died out "suddenly" did they? How can we know? For any traces to survive, the animal had to die in very special circumstances, so the absence of evidence proves nothing. And how many hectares of the Earth have been excavated?

This kind of nonsense may be good clean fun for the palaeontologists; but people in the media seem to think that *I* wish to hear of it. I do not.

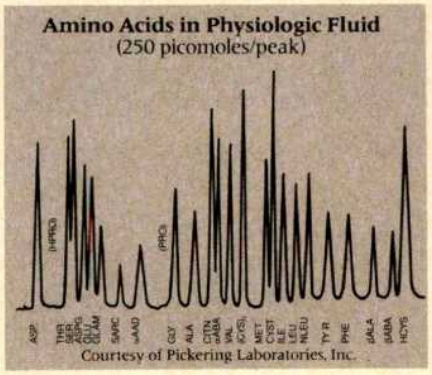
"Gilson's 121 is the best fluorometer I've used."



Mike Pickering, Pickering Laboratories, Inc.

Mike Pickering is a leading manufacturer of high-purity reagents for fluorescence detection of amino acids. He knows his fluorometers. So when Mike started using our 121 Fluorometer, we were anxious to hear what he thought of it. This is what he had to say:

"The Gilson 121 Fluorometer is simple, inexpensive, quiet, reliable. You unpack it, plug it in and it goes. I can turn it off in the evening, and when I turn it on again the next day it is working within a few minutes.

I used to use and recommend Gilson's Spectra/glo fluorometer. The 121 is even better—easier to use and more sensitive, with superior signal-to-noise ratio.

Because of our heavy workload, we need a detector that can be serviced easily. In most detectors, the flow cells are hidden—a nightmare when you have to clean them. The 121 flow cell is accessible from the front, and we don't have to bother with optical realignment when we put it back after cleaning. Actually, the only servicing we've ever needed to perform on either of our Gilson fluorometers consisted of cleaning the flow cell and replacing the lamp.

Courtesy of Pickering Laboratories, Inc.

In short, the 121 is the best fluorometer I've used."

Apply your own standards to evaluating the 121 Fluorometer. Contact your local Gilson representative or call us toll-free at (800) 445-7667.

If we need a co-ordinated policy for transport here...

While favouring the retention of the County Councils to plan and co-ordinate their own transport facilities on a regional basis, the Government is bent on abolishing the GLC.

It recognises the need for London-wide transport planning, but seeks to take this task on itself. London Transport has already been hived off to a Government-controlled quango. Now the Government proposes that the Whitehall-planned trunk road network should be extended. Whitehall will also control traffic operation on a further 300 miles of main road, and will give *mandatory* guidance on traffic schemes on all other roads.

The prime reason for change put forward by the Government – greater and more

don't we also need it here?

immediate local democracy – is, thus, a hypocritical sham. The vitally important link between public transport and traffic planning will be broken. Londoners will have no direct say in how money provided by them for transport will be spent.

Highway and traffic planning on all but the strategic network will be divided amongst 33 boroughs, so there will be no consistent policies or initiatives.

Not surprisingly, the Government has no coherent argument to support its proposals. They are recipes for jam that Londoners will have to swallow if the Abolition Bill becomes law.

Origins of five-fold symmetry

That solids with five-fold symmetry may exist seems plausible enough, but a brief bout of calculation serves chiefly as a proof of how much more remains to be done.

LAST year's gust of excitement at the recognition of five-fold symmetry in a binary alloy (of Al and Mn) by Shechtman, Blech, Gratias and Cahn (*Phys. Rev. Lett.* **53**, 1951; 1984) has already spawned its own mini-industry. The surprise, then, was that there should be evidence of any kind for five-fold symmetry when this is strictly forbidden, on geometrical grounds, in a crystal with regular translational periodicity (see *Nature* **313**, 263; 1985).

By the end of the year, D. Levine and P.J. Steinhardt had produced an outline explanation of how such a structure could exist (*Phys. Rev. Lett.* **53**, 2477; 1984). They showed how to construct "quasi-crystalline" structures in two or three dimensions which, although devoid of translational symmetry, could have local five-fold symmetry. Now attention has turned to the question whether such structures will be energetically preferred to regular crystals. But the clutch of three papers published (in *Phys. Rev. Lett*, 8 April 1985), all of which follow the same track, show such discordancies as to suggest that the issue is far from settled.

The starting point is the Landau theory of the evolution of symmetry by means of phase transitions from, say, a liquid in the process of solidification, or one solid phase in the process of transition to another. The trick, following Landau, is to suppose that the free energy is a function of parameters which describe the degree of geometrical order in the system. The first task is to determine what order parameters are allowed by geometry.

Everybody agrees that the order parameters to use are quantities D_k which are the coefficients of mass-density waves within the aggregated system, and which turn up in mathematical expressions of the form $D_k \exp(i\mathbf{Q}_k.\mathbf{R})$, where $\mathbf{Q}_k$ is some fixed vector and $\mathbf{R}$ is the vector representing position. (The symbol i is the square root of -1.) This, of course, is a periodic function of a kind that might describe plane waves travelling in direction $\mathbf{Q}_k$.

A single order parameter, associated with a single vector $\mathbf{Q}_k$ suffices to describe the smectic phase of a liquid crystal (in which molecules assume a periodic arrangement in only one dimension within the medium in which they are dissolved). The ordering of regular crystals, on the other hand, requires at least three order parameters, each of them associated with a different vector $\mathbf{Q}_k$. These must jointly describe how it is possible to choose an infinite number of directions within the crystal in which identically constituted layers of atoms are periodically repeated (and which are defined, in crystallography, by the Miller indices *hkl*). The basic vectors describing these recurring planes of atoms are not those defining the translational symmetry of the crystal, represented by the repeated translation of the unit cell, but rather the vectors of what is called the reciprocal lattice. All this is standard textbook stuff.

The neatness of the Landau treatment stems from its representation of the free energy as a power series expansion in terms of the mass-density distribution, itself the sum of terms such as $D_k \exp(i\mathbf{Q}_k.\mathbf{R})$ taken over all possible vectors $\mathbf{Q}_k$ in the reciprocal lattice. The separate terms are themselves harmonics of similar expressions involving only the basis vectors of the reciprocal lattice.

Structures with the symmetry of a body-centred cubic lattice are thus signalled by terms which are products of six D-coefficients, each corresponding to one of the six independent vectors of the tetrahedron which is the unit structure of the reciprocal lattice. Face-centred cubic symmetry is similarly signalled by terms of the eighth power, where the corresponding vectors are those of the unit octahedra of the reciprocal lattice. Telling whether a melt will crystallize in one form rather than the other may then simply be a matter of guessing whether one form of symmetry will give a smaller free energy than the other, which in practice entails much arm-waving.

The novelty now reported is that the same argument can be used to judge the likelihood that symmetries not allowed in ordinary crystallography will occur. Per Bak from the Brookhaven National Laboratory puts the case most simply by enumerating the terms in a Landau expansion corresponding to five-fold symmetry (*Phys. Rev. Lett.* **54**, 1517; 1985). The simplest case is that of fifth-power terms (products of five D-coefficients) corresponding to the five vectors represented by the sides of an equilateral planar pentagon, but this corresponds in three dimensions merely to a structure built of parallel rods whose cross-sections are the elements of the Penrose tiling of the plane.

Bak gets true five-fold symmetry by picking out the Landau terms corresponding to the null combinations of the fifteen pairs of vectors along the edges of a regular icosahedron. These show up as ten third-degree terms and six fifth-degree terms, corresponding to the ten triangles and five pentagons that can be drawn on the surface of an icosahedron. Bak readily concludes that a structure with five-fold symmetry can be stable relative to body-centred cubic structures if only the parameters are suitably adjusted.

Levine and Steinhardt (see above), together with a number of colleagues at the University of Pennsylvania and John Toner from the IBM research centre, follow a similar tack but calculate the elastic constants of a solid with five-fold symmetry to demonstrate its stability (*Phys. Rev. Lett.* **54**, 1520; 1985). As in the simple Landau treatment, symmetry restricts the range of terms occurring in the equations, but this line of argument has the virtues of showing how dislocations may be introduced into structures with five-fold symmetry (by means of pretty pictures made by driving a dot-matrix printer by the expressions calculated for the mass-density distribution) and of making explicit the hidden symmetry of these perplexing five-fold structures, which emerge as the representation in three dimensions of much simpler structures in six dimensions.

So far, there is very little physics in these discussions, but M.D. Mermin and Sandra M. Troian from Cornell University have a novel twist (*Phys. Rev. Lett.* **54**, 1524; 1985). They say that they find only metastable states for a solid with one component and with five-fold symmetry (but they appear not to have included fifth-degree terms, corresponding to the six pentagons on the surface of an icosahedron, in their Landau calculation). But how relevant is it that the only real solid in which five-fold symmetry has been found so far is an alloy, with two components?

In an alloy, there is scope for a dimension of disorder beyond those specified by the wave vectors of the simple Landau calculation. On this view, the argument goes, there is scope for generating five-fold symmetry from a blend of geometrical shape and occupancy by one or other of two components. So far as it goes, the argument is suggestive only, although the most telling evidence is a pair of dot-matrix diagrams, said to represent a cross-section from a structure with five-fold symmetry, in which one component almost exactly fills the gaps in the distribution of the other. Time, and some tangible experimental investigation, will no doubt tell whether this is what five-fold symmetry is like.

Molecular Egyptology

Mummified human DNA cloned

from J.S. Jones

ON page 644 of this issue, Svante Paabo reports the remarkable extraction and cloning of DNA from an Egyptian mummy[1]. One clone contains a 3.4 kilobase segment of DNA that has been preserved for more than two millenia. Although only one out of 23 mummies has yet produced clonable DNA, the yield from this individual approaches five per cent of that obtainable from fresh human material. Preliminary though it is, the report opens up some fascinating possibilities for future work on human evolution and archaeology.

'Fossil genes' have been identified before now: ancient snails buried in prehistoric English earthworks retain their shell colour and banding patterns[2], and comparisons of skeletal variants in living and extinct mice have been used to establish the origins of some Scottish mouse populations[3]. Even mummies retain enough of their blood group substances to allow the kinship of family groups to be confirmed serologically[4] and, on the basis of hair characters, an unidentified royal mummy from the New Kingdom has been shown to be the mother of the heretic pharaoh Akhenaton[5].

Valuable as such specific data may be, there is much more potential information in DNA sequences. The human genome possesses hundreds of thousands of genetic polymorphisms at the DNA level. Some regions (which involve variations in the number of copies of repeated sequences not dissimilar to the *Alu* sequence, to which the mummy 3.4 kilobase clone is closely related) are hypervariable[6] and can provide particularly precise estimates of human kinship and population relatedness. If these polymorphisms can be detected in mummies, we may answer some important questions about the world of our ancestors.

Information on DNA sequences is uniquely suited for tracing population movements: knowledge of the geographical distribution of point mutations in some senses provides no more than single letters in a population's genetic identity, while the ordered sequence of bases provided by its DNA haplotype gives the genetic surname itself. Thus, information on DNA sequences closely linked to the sickle-cell haemoglobin polymorphism has recently been used to establish the relationships between living populations in different parts of Africa[7]. Sickle-cell populations from Senegal and Benin differ considerably in their sickle-cell haplotype; but populations from North Africa have the same haplotype as the Nigerians. This is strong evidence that the sickle-cell mutation has arisen several times, but that the northern sickling populations originated by migration from West Africa.

Information of this kind from mummies might tell us something about population movements in ancient Africa. Ancient Egypt is thought to have been occupied by a number of distinct populations, and it is certainly the case that some dynasties of Pharaohs were drawn from foreign populations that invaded the Nile Valley. Perhaps it would be possible to test the claim of the Coptic Christians of modern Egypt to be the lineal descendants of the ancients (who disappeared from the Nile Valley under successive waves of invasion by Syrians, Greeks, Romans, Byzantines and Arabs).

DNA sequences are also useful in studying patterns of kinship and paternity within local populations. There is considerable controversy among Egyptologists about the relatedness of groups of mummies from particular sites, and there is clear potential for DNA work here. Ancient records suggest that in the 18th Dynasty, the Egyptian royal family practised incest between brother and sister or father and daughter for at least eight generations: information on their mummified DNA sequences might tell us to what extent this royal exclusivity was successful. Incest in Egypt was designed to preserve the blood line of a deity. There is something intriguing about the possiblity of learning the genotype of a god.

Mummies are not unique to Egypt: preserved humans have been found in Peru, Japan, Australasia and Europe. There is the potential here to answer some larger questions abut human evolution. What is the relationship between the native Australians and the rest of the world; were there indeed two separate invasions of Australia, as often claimed? Do the genotypes of mummified Europeans accord with the suggestion that geographical patterns of gene-frequency change in modern Europeans reflect an invasion from the East that occurred as a result of the development of agriculture? Mr Average, as defined by the population nearest the global mean for a large number of enzyme and blood-group loci, lives in the Middle East[8]: would the patterns of change in mummified humans support the idea of worldwide spread from the Middle East? An answer to any of these questions would be of extraordinary interest.

Finally, it is important to understand that Pääbo has *not* done: we cannot of course reconstitute a functional gene (let alone a living individual) from this short repeated sequence. One American newspaper reported the recent cloning of mitochondrial DNA from a specimen of the extinct quagga[9] as "US Scientists Clone Dinosaurs to Fight on after Nuclear War", and probably there will be similar sensational accounts of mummy DNA. Molecular biology rarely lives up to its headlines, but the interaction of DNA technology and archaeology may open a new phase in our understanding of human history. □

Archaeoastronomy

Halley's comet in Babylonia

from C.B.F. Walker

IN August 1984, Halley's comet was unexpectedly discovered in the British Museum or, to be more precise, on some Babylonian tablets in the museum's archives. That discovery, reported by F.R. Stephenson, K.K.C. Yau and H. Hunger on page 587 of this issue, will be exciting both for eager Halley watchers and for historians of science. It represents the first significant addition to our knowledge of the past history of the comet since the French publication of Chinese observations in 1846. It fills an important gap in the historical record, since no other account of the return of the comet in 164 BC survives. Remarkably, it also proves that the Babylonian astronomers kept records of such accuracy that we can now make a clear choice between current theories of the comet's path in antiquity.

What were the Babylonians doing recording comets? The beginnings of astronomy in Mesopotamia probably go back to the third millennium BC, when the Sumerians gave the planets and principal constellations their names but, apart from simple tables of the length of daylight and the rising and setting of constellations, almost all the early texts are concerned with astrology rather than astronomy. Writing in about AD 150, the Greek astronomer Ptolemy notes that the earliest observations available to him date from the time of the Babylonian king Nabonassar (Nabu-nasir, 747-734 BC). Although contemporary texts do not survive, later Babylonian texts also suggest that the practice of keeping a regular official record on the movements

Babylonian cuneiform tablet (BMA 41462) containing a record of Halley's comet in 164 BC (Photograph courtesy of The British Museum).

of the Moon and planets began in Nabonassar's time. The surviving texts from Babylon number rather more than 2,000, most of which are now in the British Museum. Among these, some 1,200 are fragments of observation records, a type known as 'astronomical diaries', mostly datable to between about 380 and 40 BC. Others are of a strictly mathematical character, empherides for the moon and planets. The latest text that can be dated is an almanac for AD 75.

The astronomical diaries give a day-by-day account of lunar and planetary observations and weather conditions, with monthly summaries of the height of the Euphrates, prices of various staple commodities, political events, and occasional references to comets and earthquakes, the basis for detailed mathematical systems for predicting recurrent phenomena.

The fundamental concern of the Babylonian astronomers was with the movements of the Moon and planets about the ecliptic. The fact that they moved in a precisely defined belt of stars was recognized early on, and the constellations through which they moved (at first eighteen, later reduced to twelve) were already listed in about 1,000 BC. There is a curious dichotomy between observation and theory in Babylonian astronomy. Texts of observations record the movements of the Moon and planets with reference to a list of 31 stars of varying brightness lying at unequal intervals along or near the ecliptic; distances from the 31 stars are measured in cubits (kuš), which appear to have a variable length of either 2 or 2½ degrees. The theoretical texts, ephemerides and almanacs, which first appear late in the fourth century BC, use the familiar zodiacal system of twelve equal constellations, each divided into 30 degrees (uš).

This dichotomy is also reflected in the astronomical diaries. Although these ostensibly record observations, analysis shows that all phenomena such as the equinoxes and solstices, the appearances of Sirius, and the stationary positions of planets are in almost every case derived from theoretical schemes rather than from observations.

Our primary source for the identification of the constellations is a text known as Mul-Apin, the 'Plough'. This lists the stars in various groups or 'paths' with details of their heliacal risings and settings. Other texts give descriptions of the appearance of the constellations, and there is also a very small group of drawings. At least in the zodiac belt, the constellations correspond largely to the picture familiar from the detailed descriptions of Ptolemy, but there are some interesting differences. For instance, Aries is not a ram but a 'hired worker'. More significantly, and still not fully explained, the zodiacal system does not start at the First Point of Aries, 0° ecliptic longitude, but at about 355°, a difference that extends through the whole zodiac.

In texts of observations, measurements of latitude are expressed as so many cubits 'above' (to the north) or 'below' (to the south), relative to a star or planet. Only in the lunar ephemerides is there a concept of absolute ecliptic latitude.

For chronology, the astronomical texts use the king's regnal year (or, from 311 BC onwards, the Seleucid era), the lunar month — beginning with the first sighting of the new moon — and the day. The Babylonian day began at sunset and, for astronomical purposes, day and night were divided into three watches each. Water clocks were used to time observations, the units of time being the bēru (2 hours) and the uš (four minutes). A group of 26 stars culminating at the zenith provides an additional reference point.

Edmund Halley, in the first publication of his discovery of the orbits of comets, begins by referring to a story of the classical historian Diodorus Siculus that the Chaldaeans (Babylonians) kept records of storms, earthquakes and comets, and tried to predict their occurrence. He dismisses the story as being of interest only to astrologers. Even thirty years ago we had little idea of how well informed Diodorus really was. Halley would been astonished to know how valuable the Babylonian records of comets have come to be for the study of his own comet. □

Biotechnology

New route to antibiotic creation

from Arnold L. Demain

ALTHOUGH developments in recombinant DNA (rDNA) technology have not escaped the attention of the antibiotic industry, the report on page 642 of this issue from a collaboration of British, Japanese and American laboratories that novel antibiotics can be obtained using the technique is a major step forward in biotechnology[1].

The rapid movement of rDNA technology into secondary metabolism can be mainly attributed to the long-term dedication of David Hopwood and his colleagues at John Innes Institute in Norwich to the genetics of *Streptomyces* species. Having developed plasmid and phage vectors for applying rDNA technology to these filamentous bacteria, in 1983 the Hopwood group cloned the gene of the methyltransferase of undercylprodigiosin biosynthesis in *Streptomyces coelicolor*. (Prodigiosins are pigmented antibiotics produced by unicellular and filamentous bacteria). Independently, Williams and colleagues in Houston cloned and expressed prodigiosin biosynthetic genes of *Serratia marcescens* in *Escherichia coli*[3]. The next developments were the cloning of the *Streptomyces griseus p*-aminobenzoic acid synthase gene of candicidin biosynthesis in *Streptomyces lividans*[4] at Norwich and that of a gene of clavulanic acid biosynthesis from *Streptomyces clavuligerus* at the Beecham Laboratories[5]. Finally, the Hopwood group accomplished the cloning of a segment of chromosomal DNA from *S. coelicolor* that carries the complete information necessary for the biosynthesis of the antibiotic actinorhodin[6]. Also of interest is the recent cloning of a *S. coelicolor* regulatory gene controlling the synthesis of actinorhodin, undecylprodigiosin and A-factor (a differentiation effector in streptomycetes)[7].

In order to enhance the probability of success in their attempts to produce hybrid antibiotics, Hopwood *et al.* employed microbial cultures producing three pigmented antibiotics of the isochromanequinone class. The cultured organisms were *Streptomyces coelicolor* A3 (2) (which produces the antibiotic actinorhodin), *Streptomyces* sp. AM-716 (medermycin) and *Streptomyces violaceoruber* Tü22 (granaticin). Two hybrid antibiotics — mederrhodins A

and B — were produced following the introduction of *S. coelicolor* actinorhodin biosynthetic genes (originally located on a chromosome, but placed on a plasmid vector) into *Streptomyces* sp. AM-7161. Mederrhodin A was identified as hydroxymedermycin. Cloning of *S. coelicolor* DNA in *S. violaceoruber* yielded a third hybrid antibiotic, dihydrogranatirhodin, which was found to be the C-3 or C-1 epimer of dihydrogranaticin. Evidence is put forth that each of the novel products are produced by genetic contributions from both recipient and donor microorganisms rather than merely by activation of silent genes of the recipient.

It should be noted that this is not the first technique developed for the production of hybrid antibiotics. They have been produced by 'mutational biosynthesis' for about 15 years[8]. In this technique, an antibiotic-producing strain is first mutated so that it is blocked in forming a moiety of the antibiotic and is then fed with moieties of other antibiotics. The technique has yielded hundreds of novel antibiotics but unfortunately none has become commercially important. A second method has involved natural mating between different actinomycete strains or species[9-11], and seems to produce new antibiotics by activation of latent genes in the recipient strain[12]. A third method involves protoplast fusion between strains producing different antibiotics[13].

Since new antibiotics are going to be required for many years to come in order to counteract the development of resistance in infectious microbes and the existence of diseases still unconquered by available compounds, antibiotic creation by rDNA technology is a welcome addition to existing techniques. But in case any group jumps to the erroneous conclusion that conventional efforts are now superceded, it should be understood that the rDNA technique is only a tool to be added to those of soil-screening, mutational biosynthesis and protoplast fusion. In our continuing struggle against infectious disease every new technique is welcome. □

Oceanography

Residence times of water masses in regions of the ocean

from John Woods

WHEN a water molecule involved in the global hydrological cycle finds itself in the atmosphere, it is likely to reside there for about ten days. The residence times of water in other components of the hydrological cycle are approximately: Southern Sea ice, a few months; Northern Sea ice, a few years; the World ocean, 3,000 yr; lakes, 100 yr; and the polar glaciers, tens of millenia. These estimates are based either on the ratio of volume-to-surface flux for each component, or on the radioactive age of materials mingled in with the water. There are errors in the estimates, but there is no fundamental difficulty in determining residence times for such distinct components of the hydrological system as the Greenland ice sheet, or the Mediterranean Sea. But problems arise when one tries to subdivide the components further, to discover whether water resides much longer in some parts than others. This is a question of fundamental importance for oceanography, but remains beset with confusion. The problem is first how best to delineate the separate parts and then how to determine their residence times. Equivalent questions arise in systems that range from the cardiovascular system to chemical reactors. The letter by Buffham[1] on page 606 of this issue helps to clarify matters.

Buffham's contribution is to introduce a formalism into the analysis of what he calls "region residence times" of complex circulation systems. The idea is deceptively simple and with hindsight one is tempted to dismiss it as obvious. Yet it is far from trivial and will influence, for example, the way oceanographers study their complex circulation system. What Buffham shows is that the region residence time can be deduced from a model of the system if the volumes of all regions of the model other than the one of interest are reduced to zero and by finding the residence time distribution of the resulting model. He shows that this approach is consistent with previous results and illustrates it with some simple configurations.

The method has potential for the diagnosis of region residence times in models of ocean circulation. A good example of the need for such information is provided by the problem of trying to predict climatic responses to atmospheric pollution by CO_2. Pollution decreases the net infrared cooling of the ocean, which therefore accumulates heat until the surface temperature of the ocean rises sufficiently to rebalance the surface heat budget by enhanced conduction and evaporation. The oceanographer's problem is to predict the global pattern of increasing surface temperature. For that, it is necessary to calculate the distribution of the heat anomaly created by the greenhouse effect. Early models assumed that the anomaly stayed at the surface in a mixed layer 70 metres deep. This assumption produces a characteristic (e-folding) response time of a few years. There are, however, theoretical objections to such models because they neglect the ventilation of anomalies from the mixed layer into the permanent thermocline[2]; models that include this factor give response times of several decades.

Which, if any, of these predictions is correct could be of great importance for the way that society prepares itself for changes in sea surface temperature, and hence global climate, in response to CO_2 pollution. A slow change would give time to switch to nuclear power, adapt agriculture, build up sea defences, even to move vulnerable populations. If the ventilation of the deep ocean is a factor, then the response may be so attenuated that we can enjoy the agriculture benefits of increased CO_2 production without any unpleasant change in climate. To predict the response accurately requires that the models used have the correct residence times in all the regions through which the thermal anomaly passes. Vigorous efforts are being made to test the ocean models by comparing the distributions of transient tracers in the ocean with those simulated by the models[3]. The problem is to diagnose the sources of differences, in particular to identify regions in the model that have unrealistic residence times.

That is where Buffham's formalism suggests a research strategy. Of course, ocean circulation is extremely complex and far from being fully understood, but we do know what goes into the models, and sensitivity studies related to residence time can help us to focus on the main issues. Various methods have been proposed for dividing the ocean into layers (for example, Wüst's Kernschicht-Method[4] and Worthington's isothermal surfaces[5]) but it is now generally accepted that the best division is by isopycnic (constant density) surfaces. Some models are constructed with an isopycnic distribution of grid points[6]. The advantage is that particles circulate around the permanent gyres and are mixed by synoptic-scale eddies along isopycnic surfaces; mixing through the surfaces is very much weaker and can sometimes be ignored. Using isopycnic surfaces ensures that the upper and lower boundaries of the (Buffham) regions can be treated as if they are impermeable, or only slightly leaky.

The lateral boundaries present greater

problems, which are the subject of lively debate in the ocean-circulation community. In general, the periphery of the region is defined by mean streamlines of the large-scale circulation, and by turbulent boundary layers where it meets the seabed or sea surface. These boundary layers tend to vary diurnally and seasonally, and with changing weather and climate. Since the flux of water into a particular region may depend critically on such variations, these have to be taken into account very carefully when calculating residence time.

The climatological problem focuses on the exchange between atmosphere and ocean that occurs through the surface boundary layer. Some regions of the ocean have peripheries that include the surface boundary layer only in winter, and some not every winter. It has been suggested that some regions of the North Atlantic have not been so connected to atmospheric influence since the little Ice Age over a century ago[5], and parts of the deep Pacific may have been sealed off since the last glaciation. The ventilation of such regions depends on isopycnic diffusion — which can be estimated accurately; intrusion from the seabed boundary layer — about which we know very little; and slow leakage through the isopycnic surfaces defining the top and bottom of the layer — about which we know even less.

Geochemical dating is vital for estimating the residence time of such regions. They do not necessarily lie only in the depths of the ocean. Theoretical studies have recently suggested they will sometimes be found in the upper thermocline, for example, in the ventilation 'shadow zone' off North-West Africa[7]. The regional residence time problem is central to oceanography. It must be solved before we can expect reliable predictions of climatic change. □

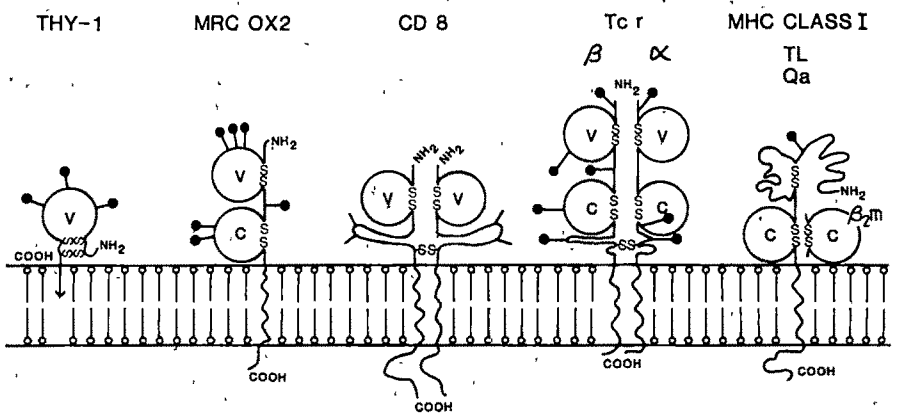
Immunology

Immunoglobulin-related domains for cell surface recognition

from Alan F. Williams

Is it acceptable to categorize cell-surface molecules as recognition structures because they show a clear relationship to immunoglobulin (Igs)? Perhaps not, but one of two newly reported members of the Ig superfamily clearly supports the recognition theme since it is a cell-surface molecule that seems to have an important accessory function in the recognition of antigen by T lymphocytes[1,2]. The other new structure[3] is also found in the T-lymphocyte lineage and it is immediately obvious from the figure and the table that much of the surface of thymocytes and unactivated T lymphocytes is covered with molecules that are now known to be Ig-related.



Human CD8 antigen is a newly-sequenced molecule with a role in T-lymphocyte activation[1,2]. It is also known as T8 or Leu 2, and corresponds to mouse Ly-2,3 antigen, which was one of the first four T-cell alloantigens described by mouse immunogeneticists[4]. CD8 is found on most thymocytes but amongst mature T lymphocytes it is restricted to those that are precursors for cytotoxic cells (T lymphocytes which kill, for example, virus-infected cells) which recognize, or are restricted by, class I MHC antigens and constitute about 25 per cent of recirculating T lymphocytes[5].

Antibodies to CD8 antigen can block T-cell cytotoxicity in the recognition phase of the response, so what is the role of CD8 in the cytotoxic reaction? It does not provide determinants that are complementary to foreign antigen but may interact with constant parts of class I MHC antigen to bias cytotoxic cells towards reacting with foreign antigen associated with the class I MHC structure[6]. This could be important if the cells' T-antigen receptors (Tcr), which bind foreign antigen plus MHC antigen, only recognize the polymorphic part of the latter, and so cannot distinguish class I from class II MHC structures. It should, however, be emphasized that an interaction between CD8 and class I MHC is not established and a clear demonstration of this would be a major advance.

The molcular forms of CD8 antigen are complex and vary between species. Mouse CD8 is a heterodimer consisting of an α- or α'-glycoprotein chain (M_r 38,000 and 35,000), which expresses the Ly-2 alloantigenic determinant, and a β-chain (M_r 30,000) which expresses the Ly-3 determinant[7]. Rat thymocyte CD8 also has two dissimilar chains, (M_r 38,000 and 34,000)[8] but human CD8 consists of only one chain ($M_r \sim 34{,}000$) which forms a homodimer[9], although this is further associated with a 45,000 M_r structure on thymocytes. The human antigen was cloned after transfection of mouse L cells with human DNA[1,2,10], which led to the cloning of equivalent mouse and rat antigens.

The structural features and relationships of human CD8 are summarized in the figure. Each chain contains one domain that resembles an Ig variable (V) domain, in particular an Ig light-chain V. Following this is a sequence like an Ig hinge, a transmembrane piece and a short cytoplasmic tail. The glycoprotein structure is unusual in having only *O*-linked carbohydrates[9] (there is an Asn-Pro-Thr sequence in CD8 but the proline debars *N*-glycosidic attachment at the asparagine). The larger chain of the mouse heterodimer (Ly-2) is equivalent to human CD8 (L.A. Herzenberg *et al.*, J.R. Parnes *et al.* personal communications) while, surprisingly, the equivalent in the rat is the smaller chain (P. Johnson *et al.* personal communciation). The mouse and rat chains have three and one sites for *N*-glycosylation, respectively, so differences in glycosylation may account for the species variations in size of the chains. The other CD8 glycoprotein chain of rodents remains to be cloned; its sequence will be of considerable interest to the full understanding of a set of molecules that seem to show considerable diversification in evolution.

The second new member of the Ig superfamily is the rat MRC OX-2 antigen,

Models for Ig-related molecules found on thymocytes and/or unactivated T lymphocytes. Circles indicate segments related to Ig domains with similarity to a V-domain (V) or C-domain (C) folding pattern. Double S symbols indicate possible positions of disulphide bonds but these are established only for Thy-1 and MHC class I antigens. *N*-linked carbohydrate structures (Y) are determined by positions of Asn X Thr or Ser in the protein sequence but the number of *O*-linked structures (|) in CD8 is arbitrary and the positions are guesswork. For Thy-1, see ref. 25; OX-2, ref.3; CD8, refs 1 and 2; Tcr, ref. 26; MHC class I, TL, Qa, ref. 27.

which is one of the new generation of molecules that has been discovered by means of monoclonal antibodies. This antigen was initially of interest to my colleagues and me because of its expression on thymocytes and neurones, as is the case for Thy-1 antigen[3]. OX-2 is also on all endothelial cells, B cells, activated T cells and follicular dendritic cells. There is no evidence concerning its function and no obvious functional correlation between the cells that express the antigen, except that all may be involved in recognition events. The predicted structure for OX-2, which is included in the figure, shows that it looks remarkably like a single Tcr chain or Ig light-chain with a membrane-spanning segment added. The sequence of OX-2 domain I fits well with the V-domain pattern, perhaps with a closer relationship to Thy-1 than to other sequences.

The Ig-domain hypothesis[11] says that the evolutionary starting point for Ig was a single domain which gave rise to a structure like an Ig light-chain from which all the Ig chains evolved. This concept holds good for all the molecules in the figure and it seems likely that the primordial molecules were involved in cell surface functions. It is particularly interesting that the functions of the Ig-related molecules include interactions between members of the Ig superfamily[12] (for example, Tcr and MHC; Poly Ig R and Ig A or Ig M; CD8 and MHC class I?; CD4 and MHC class II?). Such reactions may be the general rule, which suggests that the starting point was a recognition system in which Ig-like domains on one cell interacted with identical structures on another. Gene duplication and divergence could have led to interactions based on pairs of dissimilar Ig-related molecules and to the systems that now function in vertebrates.

Since the lymphocyte-based immune system has not been convincingly shown in invertebrates, it is probable that Ig-like structures first evolved on cells that had no immune function. Primitive sensory cells may have been the starting point since vertebrate neurons express Thy-1 and MRC OX-2 antigens and these seem the best candidates for contemporary structures corresponding to the postulated one- and two-domain primordial molecules. It could be argued that the CD8 structure is close to the primordial domain, except that it is most closely related in sequence to light-chain V domains rather than being apparently equidistant from the various V-like structures, as is Thy-1 antigen. Also CD8 and V-kappa genes are closely genetically linked[13] in man and mouse suggesting that they had a common immediate precursor, possibly with a two-domain structure. □

Table 1 Some surface molecules of thymocytes and unactivated T lymphocytes

Molecules	Molecular nature	Commonly-used names: Man	Mouse	Rat	Expression	Comments
Ig-related						
T-antigen receptors (Tcr)	gp43, gp40	No antibodies react with all Tcr			Thymocytes, T-helper and T-cytotoxic cells	Tcr seems the same for T-helper and T-cytotoxic cells[26]
MHC Class I	gp43; p12	HLA A,B,C	H-2 K, D	RT1A	Many cells, not brain, not 70% of thymocytes	Recognized along with foreign antigen by Tcr
TL (CD1?)	gp43, p12	NA1/34, T6	TL	NA	Thymocytes and leukaemias	Similar to and genetically linked to MHC I
Qa	gp43, p12	NA	Qa	NA	Lymphoid, others?	Similar to and genetically linked to MHC I
Thy-1	gp18	Thy-1	θ, Thy-1	Thy-1	Neuronal and fibroblasts in all species studied, lymphoid in rodents, not man	Anti-Thy-1 mitogenic for mouse T cells and affects behaviour of neurons[18]
MRC OX-2	gp47	NA	NA	OX-2	Thymocytes, neuronal, endothelium, follicular dendritic, B cells	Appears before Thy-1 in brain development[19]
CD4	gp55	T4; Leu 3	L3T4	W3/25	Thymocytes, T helpers, macrophages	Antibodies block T-helper response to antigen Homology to Ig reported in abstract[20]
CD8	gp38, gp34 or gp34×2	T8, Leu 2	Ly-2, 3	OX-8	Thymocytes, T cytotoxic, NK cells	Antibodies block T-cytotoxic cell reactions
Not Ig-related						
CD3	gp25, gp20, p20	T3, Leu 4	NA	NA	Thymocytes and mature T cells only	Associated with Tcr, antibodies mitogenic if crosslinked at surface, gp20 not Ig-related[17]
L-CA	gp180-240	L-CA	T200, Ly-5	L-CA	All leucocytes but not erythroid cells Absent from other tissues	Antibodies have functional effects Sequence shows M_r 80,000 cytoplasmic domain[21]
LSGP	gp95	L10	NA	W3/13	Thymocytes, T cells, neutrophils, plasma cells, brain	Mucin-like, peanut lectin receptor, deficiency may cause Wiskott-Aldrich syndrome[22]
LFA-1	gp180, gp90	LFA-1	LFA-1, Ly-15		Most leucocytes	gp90 shared with Mac-1; gp180 may be related to interferon[23] Antibodies inhibit T cell responses
Relationship to Ig unknown (not all antigens listed)						
CD2	gp50	T11, LFA-2	NA	NA	Thymocytes, T lymphocytes	Receptor for sheep erythrocytes Antibodies can be mitogenic[24]
CD5	gp67	T1; Leu 1	Ly-1	OX-19	Thymocytes, T lymphocytes, B-lymphocyte subset	Antibodies augment T-lymphocyte responses

Names for antigen molecules are traditional or, where possible, the new nomenclature for human antigens is used (see ref 14) Many of the data are described in ref 14 (man), refs 7 and 15 (mouse) and ref 16 (rat) Equivalent human, mouse and rat antigens are grouped where the similarities seem strong but sequence data will be needed ultimately to prove species equivalence

NA, no antibody available (but at the DNA level human OX-2 has been identified (M J Clark, G McCaughan and A N Barclay, unpublished observations) as has mouse CD3 (ref. 17)). gp, Glycoprotein, p, protein, numbers give the approximate relative molecular mass (M_r) $\times 10^{-3}$

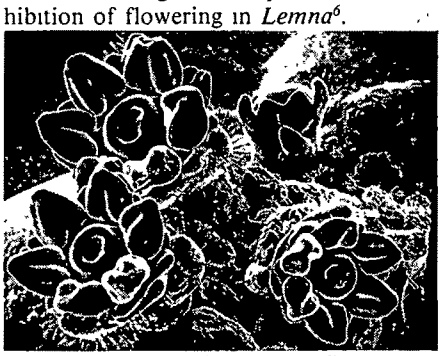
Plant morphogenesis

Oligosaccharide floral messages?

from Keith Roberts



ON page 615 of this issue, Peter Albersheim and colleagues present some initial results that clearly suggest new explanatory hypotheses for the normal growth and development of plants Their general suggestion is that locked up in the bewildering array of very complex polysaccharides that form the plant cell wall there are short oligosaccharide sequences which, when released, form a set of important signalling molecules that plant cells can use in a variety of ways[1].

There are fundamental differences between the ways that plants and animals develop, most of which rest on the fact that plant cells are immobilized inside a relatively rigid cell wall. Since the wall precludes cell movement, orderly morphogenesis of plants and their organs must depend crucially on a combination of precisely positioned planes of cell division, and controlled and coordinated cell growth[2]. It is a salutory fact that we know very little either about the nature of the spatial controls, or about the molecular mechanisms involved in the determination and control of morphogenetic events. This great area of relative ignorance is all the more surprising when one considers that the plant kingdom offers wonderful experimental systems with unparalleled plasticity of developmental programmes, and that intensive research on plant growth regulators has been going on for over half-a-century.

The whole field is clearly in need of new models that can stimulate fresh approaches to the problem, and the suggestion that oligosaccharides are regulatory molecules provides a good start. The particular experiments reported on page 615, which demonstrate that artificially produced cell wall fragments can switch the experimentally induced pathway of morphogenesis in a model plant system, should be seen in the context of the more general hypothesis.

In the course of chemical work describing the variety of polysaccharides in the primary cell wall, Albersheim and his group found that oligosaccharides released in very low concentrations from the wall of the fungal pathogen *Phytophthora* triggers the expression of plant genes in a response that leads the plant to produce an antibiotic, or phytoalexin[3,4]. (Oligosaccharides that induce plants to produce phytoalexins are called elicitors and their role in stress and pathogenicity has been discussed recently in these columns[5]) It was later found that fragments of the plant cell wall, or endogenous elicitors, might also be involved in the response This fact, linked with the general realization that signalling molecules in plants are probably small water-soluble molecules that seem not to include the peptide and amino acid derivatives used in animal cell signalling, led to the idea that cell wall oligosaccharides might be used more generally by plants as signalling ligands.

Albersheim coined the term oligosaccharins for regulatory molecules that are derived from plant cell wall polymers. Those that have been described so far are 7-15 sugar residues long and have all been obtained either by chemical or enzymatic degradation of the pectic or hemicellulosic fractions of the cell wall. The range of biological effects that oligosaccharins can elicit is wide and includes the inhibition of auxin-induced growth in peas and the inhibition of flowering in *Lemna*[6].

Scanning electron micrograph of flowers on a tobacco explant, each with an ovary surrounded by stamens (Courtesy L Jehanno and K Tran Thanh Van)

The new data, which considerably extend the 'oligosaccharin hypothesis' to include a possible regulatory role for oligosaccharins in normal organogenesis, come from a colloboration between Albersheim's group and that of K. Tran Thanh Van. In her elegant system of controlled morphogenesis in thin cell-layer explants of tobacco, controlled combinations of auxin, cytokinin, and *p*H are used to dissect the regeneration of roots, vegetative buds, floral buds or callus on the explants[7]. In the present experiments sets of oligosaccharides, one prepared chemically and the other enzymatically from cell-wall pectin, are shown to switch the expected pathway of morphogenesis at concentrations estimated to be no more than 10^{-8}-10^{-9} M. Thus, with one of the preparations, flower buds can be switched to vegetative buds at *p*H 3.8, but at *p*H 6.0 the switch is in the opposite direction. With the other preparation, flowers give way to vegetative buds at *p*H 3.8, roots are induced instead of only callus at *p*H 5.0, and at *p*H 6.0 calus and vegetative buds become callus and roots.

Although neither the chemical identity of the oligosaccharins involved nor any hints as to their mode of action are yet known, the effects themselves are very dramatic and immediately pose exciting questions about the possible role of the oligosaccharins *in vivo* and in the practical context of plant regeneration. The area of work in plant development opened up by oligosaccharin probes is enormous, and already collaborations are in hand to examine the changes in gene expression induced by them in this particular system.

What these experiments throw into very clear focus is our ignorance of the molecular events involved in cell signalling and recognition mechanisms in plants. As yet, know next to nothing about cell surface receptors or signal transduction. The tobacco explant system, with its interaction of hormones, sugar and *p*H, may be too complex for comfort, but the oligosaccharin hypothesis certainly opens the way to a molecular understanding not only of plant morphogenesis but also of plant cell receptors and signalling mechanisms in general. □

Early Americans

Land bridge of Duvanny Yar

from Paul A Colinvaux

PRESENT uncertainties about the history of the Bering land bridge and hence of the first peopling of the Americas seem close to resolution. The debate among Siberian geologists is being settled in favour of the modern interpretation, closely associated with Academian N.A. Shilo, who visited Alaska last summer and discussed with a US team what studies would be necessary in Siberia and Alaska to resolve many of the remaining uncertainties.

In the last glaciation, the Bering land bridge fused Siberia to Alaska as an ice-free plain of continental proportions (see figure). Archaeologists who claim that people lived in America more than 20,000 years ago require the land bridge to have been inhabited early in glacial times; those who dismiss all evidence for pre-Clovis peoples in the New World are content for the first inhabitants of the land bridge to have been in place only in the late glacial, shortly before melting glaciers flooded their new homeland. Either way, the inhabitants orig-

Map of the Bering Strait study area. The broken line indicates the Bering land bridge and asterisks mark the sites of the pollen analyses that have been made. Will they be matched in Siberia?

inated in Siberia, where people are known to have lived as hunters at the forest steppe ecotone over thirty thousand years ago.

The contribution of Shilo and his followers has been to define the geomorphology of north-east Siberia so explicitly that firm environmental limits for the land bridge in full glacial times are established. In eastern Siberia, large rivers flow north and are separated by interfluves that are hundreds of kilometres wide. The surface of the interfluves has a topography of flat hillocks and depressions called *yedoma* and *alasy*. It has been evident for some time that the *alasy* depressions are thermokarst features melted out of a once uniform plain of *yedoma* silt.

For many years, Siberian geologists identified the *yedoma* deposits as alluvium and suggested that there had been huge shallow lakes in which the silt settled. Shilo came to question this view during his many years in Siberia, working on gold placers (as a geomorphologist and as a student of frozen mammoth carcasses), before he became head of the Far-Eastern Science Research Centre in Vladivostok[1]. He argued that the *yedoma* silt was not alluvium, but loess. This hypothesis has been further developed by Boris Yurtsev[2] and S.V. Tomirdiaro[3], who have marshalled the data of palaeobotany, mineralogy and geomorphology until the argument for a loessic origin for the *yedoma* has become compelling: Thus older Russian descriptions of Beringian environments are turned on their heads, with 'dry, cold and windswept' substituted for the 'wet and flooded'; it now seems that the silt was blown over an arctic landscape and frozen into place. The dry, cold time of the loess accompanied the Duvanny Yar (Wurm-Wisconsin) glaciation in Siberia. The cutting of *alasy* depressions by thermokarst is now dated, by radiocarbon, to the Holocene.

D.M. Hopkins, the US authority on the Pleistocene geology of Bering Strait[4], who travelled to some of the Siberian sites with Yurtsev in 1981, agrees with the interpretation of the Shilo school. The *yedoma* is comparable to the 'muck' of the Yukon gold placers, and to the thick loess mantle on the central Seward Peninsula[5]. Hopkins also finds evidence for sand, as well as loess, blowing across Alaska, from deep in the interior down to the south land-bridge coast at the Pribilof Islands (see figure).

This view of the land bridge of Duvanny Yar times as dry, cold and barren has also been developed independently from the evidence of pollen in lake sediments. Pollen spectra dated to the land bridge on the Alaskan side represent a tundra that has no exact modern analogue and probably had a less complete vegetation cover than does modern Alaska. The extreme view is that of Ritchie and Cwynar[6], who use the first good pollen influx data to argue that the land-bridge tundra was as sparse as polar desert. Other pollen analysts argue for something like a dry facies of modern tundras but with fewer sedge meadows and almost devoid of dwarf shrubs[7,8]. In any case, pollen data seem quite incompatible with a more productive vegetation, like steppe or grassland. When Yurtsev talks of the 'tundra-steppe' that covered the *yedoma* as it formed, he likens this to the sparse tundra of modern Wrangel Island in the Arctic Ocean, his ideas thus converging with the conclusions of pollen analysts on the Alaskan side[2].

This reconstruction is in direct conflict with the hypothesis that the Duvanny Yar land bridge supported a complex biocoenosis of big game animals and, hence, a considerable production of plants — the so-called 'mammoth steppe'[8-10]. Archaeologists who argue for early peopling of the New World rely on the availability of considerable populations of mammoths and other game as the resource of their first Americans[11,12]. If the Shilo school and the Alaskan pollen analysts interpret the Duvanny Yar ecosystem correctly, it is difficult to see how the necessary population of big game could have been supported. In this event, interest would turn to the late glacial land bridge, when changing climate could have made the southern land-bridge coast more hospitable, just in time for the immediate ancestors of the Clovis culture to supply the first Americans.

As accelerator-dating increasingly brings into question claims of early American sites of human habitation[13], the idea of a frigid barrier of a land bridge, more than 14,000 years ago, becomes even more appealing. But obviously this reconstruction requires further testing and an important test will be found in applying pollen analysis to lake sediments of the Siberian side. With that in mind, the Climate Dynamics and Polar Earth Sciences programmes of the US National Science Foundation have provided funds for a team from the University of Washington and Ohio State University to work with Academician Shilo and his group on raising sediment cores from a series of lakes in Soviet Beringia. The US team will take their rubber boats and Livingstone sampling equipment, closely modelled on the equipment first introduced into palaeoecology for use in Alaskan studies[14]. The two teams plan to use this equipment in Siberia later this year to raise duplicate cores from each lake, and thereafter to conduct pollen and other palaeoecological analyses in parallel.

East and West are divided at the Bering Strait, but we propose to standardize research methods for a final reconstruction of the years when the Strait was abolished and the continents were fused. □

100 Years Ago

Far-sightedness

IN THE spring of 1837 I was travelling from Rome, northwards, by 'Vetturino,' and from the summit of Apennine on the road between Florence and Bologne, I saw, with astonishment, the whole range of the Swiss Alps, not merely distinguishable but conspicuous. Measured on the map in a direct line the nearest part of the range was distant about 200 miles The extreme portions, including Mont Blanc, were considerably more. I have no doubt that the atmospheric conditions were unusually favourable As a peasant, living on the spot, shortly passed, I asked him what mountains they were — to which he immediately answered to my surprise, that they were the mountains of Switzerland.

J HIPPISLEY

Molecular biology

Reverse transcriptase rides again

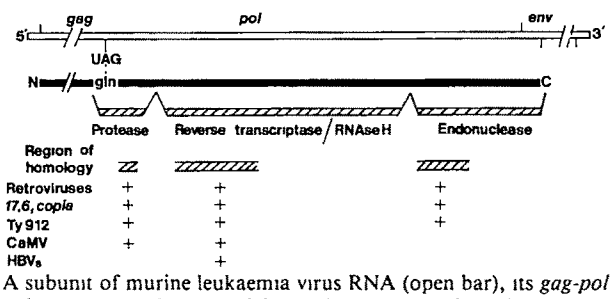
from Harold E. Varmus

JUST fifteen years ago an explosive growth in RNA tumor virology was triggered by the discovery of reverse transcriptase[1,2] — the enzyme of retroviruses that copies their RNA genome into DNA, which can then become integrated as a 'provirus' into the DNA genome of infected cells. Yet reverse transcriptase in recent years seems to have given up centre stage to oncogenes and proto-oncogenes. If so, there is now furious activity in the wings: recent findings about the *pol* genes of retroviruses — and about related genes in other viruses and in transposable elements of flies and yeast — signal a new era of discovery likely to influence such diverse topics as mechanisms of transposition, molecular evolution, and translational fidelity.

Pol coding domains

What has come to be called a retroviral *pol* gene consists of a large open reading frame, situated between reading frames for core (*gag*) and envelope (*env*) polyproteins, that encodes a protein with both reverse transcriptase RNA-directed DNA polymerase and ribonuclease H activities[3] (see the figure). Most retroviruses express *pol* by first synthesizing a *gag-pol* polyprotein (discussed further below) that is subsequently cleaved to mature components, including a virus-associated DNA endonuclease[4-6], most likely by a virus-encoded site-specific protease[7-9].

Structural studies of the DNA endonuclease present in avian leukosis and sarcoma viruses (ASLVs) suggested its derivation from the 3′ end of *pol*[4,10], a suggestion that has since been extended to the endonucleases of other viruses (see below). The source of the protease has been more enigmatic: though associated with the carboxyterminal product of the ASLV *gag* polyprotein[4], protease activity has not been detected in murine leukemia virus (MLV) *gag* proteins [11]. Analysis of a *pol* frameshift mutant competent to process its *gag* polyposition and comparison of the amino-terminal sequence of MLV reverse transcriptase with the nucleotide sequence of *pol*[12] suggests that there is room in the region of *pol* immediately downstream of *gag* to encode the protease isolated from MLV particles.



Strong confirmation of these predictions is now in hand. A partial amino acid sequence of a protease purified from MLV corresponds to the sequence predicted from the 5′ end of *pol*[13] (also see below); and a short in-frame deletion mutation, engineered in the same region, cancels processing of both *gag* and *gag-pol* precursors[14]. (The mutant appears to assemble virus particles with normal efficiency and, suprisingly, to contain normal levels of *in vitro* reverse transcriptase activity, though unable to synthesize viral DNA upon infection.)

Site-directed mutagenesis has also been used to document the importance of the putative endonuclease coding domain at the 3′ end of the *pol* genes of MLV[15,16], ASLV[17], and spleen necrosis virus (SNV)[18]. Both deletion and point mutations in this region of cloned MLV and SNV DNA produce virus particles that synthesize apparently normal linear and closed circular DNA intermediates after infection, but fail to integrate viral DNA with the efficiency and precision characteristic of wild type virus[15,16,18].

What are the biological roles of the endonuclease? At least two recombinatorial functions can be envisioned. First it may be responsible for a staggered cutting of chromosomal DNA (ostensibly in a sequence-independent manner) to yield the virus-specified four, five, or six base-pair duplications of host sequence that are found to flank proviral DNA. Second, the endonuclease may carry out sequence-specified tailoring of viral DNA so that proviruses are uniformly joined to host DNA at sites two base pairs from the ends of viral long terminal repeats (LTRs), within the inverted repeats that conclude the LTRs[19]. There are now strong reasons to believe that during infection and integration the endonuclease recognizes and is to cut circle junctions — the palindromic sequences formed when the inverted repeats at the end of unintegrated linear DNA are joined to yield circular DNA species. Experimental insertion of a small circle junction fragment into an SNV vector creates a second integration site within the viral genome[20] and integrity of the inverted repeats is mandatory for integration [21]. In addition, when an ALSV endonuclease is incubated with single-stranded viral DNA *in vitro*, it prefers to cut close to the expected sites[22].

The claim that hepatitis B viruses (BHVs) and cauliflower mosaic virus (CaMV) replicate through RNA intermediates with the help of reverse transcriptase (see ref. 23) has received striking support from computer searchers: Toh *et al.* were first to report a persuasive relatedness between the amino-terminal portion of retroviral reverse transcriptases and products of long unassigned open reading frames of HBVs and CaMV[24]. Comparisons of products of disparate retroviruses have shown that all three functional domains described for the MLV *pol* gene are strongly conserved, although not always within a single open reading frame (see below)[25-27].

Similarly successful games have now been played with the newly-determined sequences of the mobile *copia*-like genetic elements of *Drosophila* and the mobile *Ty* elements of *Saccharomyces*. These transposons had previously been recognized to resemble retroviral proviruses from their general organization and some limited sequence similarities within, and adjacent to, their LTRs (reviewed in ref. 28). Saigo, Miyata and their colleagues[27,29] have since found that protein sequences homologous to retroviral protease, reverse transcriptase, and endonuclease are encoded within the second of three long open reading frames of the *copia*-like element *17.6*, where they are arranged similarly to the domains described for MLV *pol*. In *copia* itself, which has only a single, extensive open reading frame, the endonuclease region instead lies between an upstream protease and a downstream reverse transcriptase region[30]. The yeast element, *Ty* 912, has a *copia*-like arrangement of domains within the second of two open reading frames[31].

A subunit of murine leukaemia virus RNA (open bar), its *gag-pol* polyprotein product (solid bar), the enzymes cleaved from the polyprotein (hatched bar) and regions of sequence homology between murine leukaemia virus and other genetic elements

Transposition via RNA

There is, at least, superficial congruence between the sequence relationships listed in the figure and the evidence available about their predicted functional consequences. Thus, for HBVs and CaMV, which contain reverse transcriptases but not endonucleases, the replication cycle seems to include RNA-directed DNA synthesis but not orderly or efficient integration into the host genome. Several transposable elements of *Drosophila* and *Saccharomyces* are organized in a fashion consistent with the use of a retrovirus-like integrative mechanism, dependent upon the putative endonuclease domains; but, until recently, evidence for reverse transciption has been limited to the existence of linear and circular DNA forms of *copia*-like elements that resemble unintegrated retroviral species[32-34] and virus-like particles associated with *copia* RNA that display incompletely studied reverse transcriptase activity[35].

This rather tentative situation has now been dramatically altered by experiments that show beyond reasonable doubt that *Ty* elements, like retroviral proviruses,

transpose via RNA intermediates. For what seems likely to rank among the ten best scientific stories of the year, Boeke *et al.* constructed a molecularly-tagged *Ty* element[36], in which the promoter of the 5′ LTR is replaced by the inducible *GAL1* promoter, so that *Ty* transpositions to a target yeast plasmid[37] could be shown to be dependent on transcriptional activity. Moreover, *Ty* LTRs were shown to be regenerated in each transposition cycle, in the manner of retroviral LTRs such that differences between the LTRs in the original element are eliminated from the newly synthesized copy received by the target plasmid. Finally, in a manoeuvre destined to convince even those unfamiliar with the acrobatics of retroviral replication that an RNA intermediate is used, Boeke *et al.* prove that an intron placed in an innocuous position in the moveable element can be precisely removed during transposition.

In the wake of the *Ty* results, few will question the hypothesis that *copia*-like elements of *Drosophila* and retrovirus-like elements of mammals (for example, VL-30 and intracisternal A particle DNAs[3]) also transpose and amplify their numbers through RNA intermediates, even though they lack the ability to make extracellular virus particles. But acceptance of this idea carries with it an evolutionary dilemma: are retroviral proviruses of vertebrates, with their capacity to spread as viruses from cell to cell and animal to animal, to be considered as advanced versions of more primitive elements present in all eukaryotes? Or are such elements the remnants of ancient retroviral infections, retaining only in occasional instances the capacity to mediate limited (intracellular) transposition?

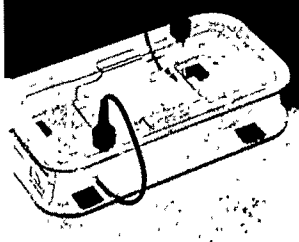
Translational suppression

It has been apparent for several years that something peculiar must occur at the boundary of *gag* and *pol* (see figure) to allow synthesis of a *gag-pol* polyprotein, at 1-5 per cent the efficiency of *gag* polyprotein[3]. From the first definitions of the precursors to MLV and ASLV reverse transcriptases[38,39], at least two possibilities have been on the table: either an inefficient splicing event generates a *gag-pol* mRNA that lacks the *gag* terminator, or the terminator must occasionally be suppressed or otherwise bypassed in translation. Those favoring simple termination suppression took heart some years ago from the demonstration by Philipson *et al.*[40] that MLV virion RNA could be translated *in vitro* to yield both *gag* and *gag-pol* precursors, and that the latter was increased at the expense of the former by addition of yeast amber-suppressor tRNA. In similar experiments with Rous sarcoma virus (RSV) RNA, however, addition of suppressor tRNA provoked the synthesis of a protein only slightly longer than the *gag* precursor[41]. Nucleotide sequencing then revealed that *gag* and *pol* are in different, albeit overlapping, reading frames in the RSV genome[42], whereas MLV *gag* and *pol* are in the same frame and separated only by an amber codon[43], as anticipated from the *in vitro* translation studies.

The translational supression school thereupon fell into mild disfavour and, since all retroviruses generally solve their problems in similar ways, it was widely assumed that they must make a small amount of atypically spliced *gag-pol* mRNA, despite the absence of recognizable splicing signals. The constitutive synthesis of *gag-pol* protein *in vitro* was ascribed to inadvertent packaging of *gag-pol* mRNA.

Oroszlan and his colleagues[13] have now turned all eyes back to translational suppression, by showing unambiguously that the amber terminator of the MLV *gag* is suppressed during synthesis of the *gag-pol* polyprotein. Amino-terminal sequencing of the protease of MLV shows it to be a cleavage product of the region of the polyprotein encoded by the *gag-pol* junction. More importantly, the first four amino acids are encoded by the *gag* sequence preceding the amber codon (UAG in figure); those beginning with number six are encoded by the *pol* sequence following the terminator; and the fifth amino acid is glutamine (gln in figure) in at least 80-90 per cent of the protease molecules. What determines that the amber codon is misread as glutamine instead of termination 1-5 per cent of the time? What species of tRNA is involved? Can other genes be affected in this way?

These self-evident questions are accompanied by less obvious, but no less provocative, ones. What should we now make of RSV, in which *gag* and *pol* are out of frame? Is there a mechanism for translational frameshifting that works as regularly upon RSV RNA as amber suppression does upon MLV RNA? Oblique suggestions that this is the case have come from recent studies of yeast *Ty* elements. The two major open reading frames of *Ty* 912 are overlapping and the second has no initiation codon until well into the open frame; rigorous attempts to discover an appropriately spliced mRNA have failed; and the size of *Ty-lacZ* fusion proteins indicates that translation of the second reading frame initiates from the 5′ end of the first[31]. From this and a related study by Mellor *et al.*[44], it seems likely that translational frameshifting is required for expression of the second frame, which is encodes proteins related to the products of retroviral *pol* genes.



Cursory examination of the relationships between the first (*gag*-like) and second (*pol*-like) coding domains of a number of retrovirus-related elements shows a tantalizing potential for diversity in the synthesis of *pol* proteins and their homologues. In *Ty* 912, the second frame is '+1' with respect to the first[31], whereas the RSV *pol* frame is '−1' with respect to *gag*[42], *and the same is true for the Drosophila* element *17.6*[29]. On the other hand, *copia* seems to be similar to MLV, with *gag*- and *pol*-like sequences in the same frame, but not separated by a termination codon[30]. The frequency of termination codons between the *gag* and reverse transcriptase coding regions of HTLV-I[45] and II[46] and bovine leukaemia virus[47,48] demands either splicing or multiple suppression events for expression of *pol*; however, translation of sequences that begin near the 3′ end of *gag* in the '−1' frame would yield proteins related to retroviral proteases[27,49].

In sum, an astonishing amount has been learned recently about functional and structural similarities among the *pol* genes of retroviruses and related elements — a good augery for the next fifteen years of reverse transcription. □

Novel DNA sequence representations

SIR — Recent contributions from Lathe and Findlay[1] and Hayashi and Munkata[2] are manifestations of a widespread concern that the conventional (letter-sequence) representations of long DNA sequences are unsuitable for purposes other than elementary information storage. With regard to comprehensibility, such data appear to be analogous to the atomic coordinate tables seen in the specialized journals of X-ray crystallographers. Data in such form cannot be remembered, compared to other similar data, or scanned for certain features without some computer manipulations.

Lathe and Findlay's suggested sequence representation is based on four vertical lines of unequal lengths, each assigned to one of the four nucleotide bases[1]. (This idea appears to be related to the more general computer-based approach used by Daniels *et al.*[3].) For relatively short sequences the method creates attractive mnemonics capable of reflecting certain symmetry features of the sequence. However, for long DNA sequences of several thousand nucleotides this method would be limited by the same problems as those of the letter-sequence method — a compromise between excessive figure size and legibility, lack of indication of global sequence characteristics, and the impossibility of resolution adjustment. The conventional letter-sequence method seems adequate for short DNA where the conveyance of the short-range details of the information is the most important factor. Thus, the suitability of any alternative method must be tested not only on short but also on long DNA sequences.

We have proposed a graphic representation method[4-6] based on the idea of mapping the information content of a DNA sequence into a three-dimensional space curve such that the shape of the curve represents the sequence of nucleotides. A short space vector of characteristic direction is assigned to each of the four nucleotides (Fig. 1) and the curve is assembled from such vectors by joining them head-to-tail in the order of the nucleotides in the DNA sequence. The front and the side views of these 'H-curves' (or their stereoscopically viewed three-dimensional version) can provide not only short-range detail but can also reflect global nucleotide-distribution trends. For instance, DNA regions rich in certain nucleotides will result in H-curve regions shifting in characteristic directions. An important property of these curves is that they can be generated or viewed at different degrees of resolution. At high resolution the individual nucleotides of the sequence are observable but at lower resolution, (when curves are condensed to a relatively short vertical length) the regional variations of nucleotide-distribution patterns along the DNA sequence are emphasized. This latter property of our curves makes them particularly suitable for representing very long DNA sequences. (We recently published the evaluation of the H-curve of the λ genome sequence of 48,502 nucleotides[7].)

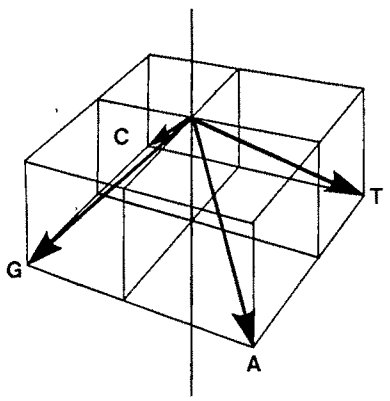

Fig. 1 Perspective illustration of the four small elemental space vectors used to depict the four nucleotides in the H-curve method of DNA sequence representation. The H curve for a DNA sequence is constructed by a head-to-tail assembly of these vectors according the nucleotide sequence of the DNA.

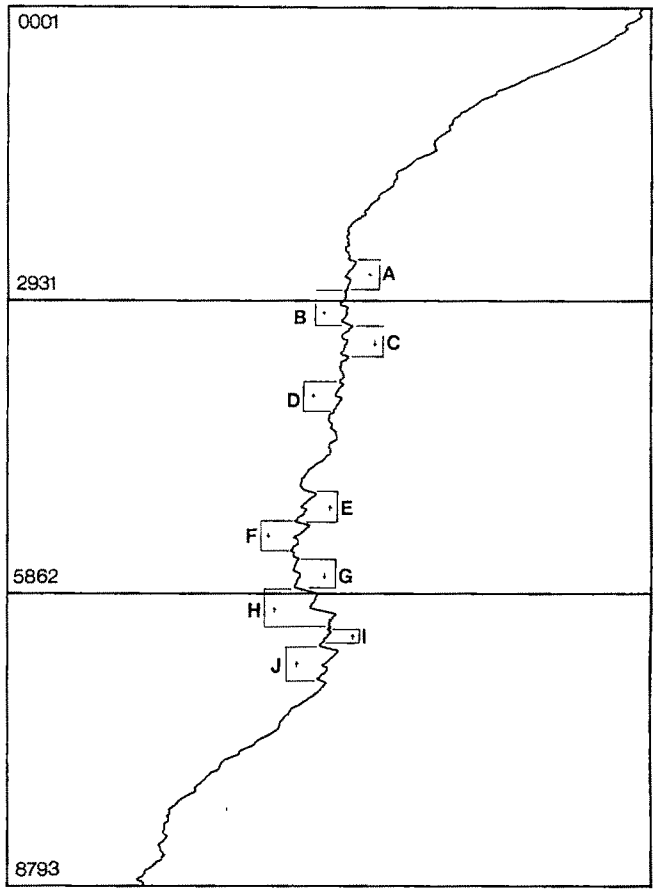

Fig. 2 The H curve of an 8,793-nucleotide-long human DNA sequence (an expressed isotype (5β) of the β-tubulin gene cluster[8]). The projection of the curve shown is the front view with the elemental vectors (here unresolvable) for the G and C nucleotides pointing to the left and those for the A and T nucleotides to the right. The vertical central portion of the curve corresponds to an unusual intron containing a cluster of ten 300-nucleotide-long *Alu* sequences (sections marked with letters). The top of the curve is the 5′ end. The vertical reference lines are 2,931 nucleotides apart and the smoothing factor[5] (*w*) was 10.

The curve shown in Fig. 2 illustrates the utility of our representation method for the display and location of characteristic repeating elements on a lengthy eukaryotic DNA sequence.

TATHE AND FINDLAY REPLY — Sequences of the four letters G, A, T(U) and C, are particularly intractable to visual analysis. An ideal format would (1) reveal local features such as recognition sites for enzymes interacting with nucleic acids; (2) reveal large-scale base distribution patterns, and (3) be machine-readable. It is improbable that a single method can meet all three requirements.

The methods proposed by Hamori[1] and ourselves[2] are quite different. We are nevertheless struck by the parallels between the two formats (angle-vector H-curve and line-extension) and the two methods of

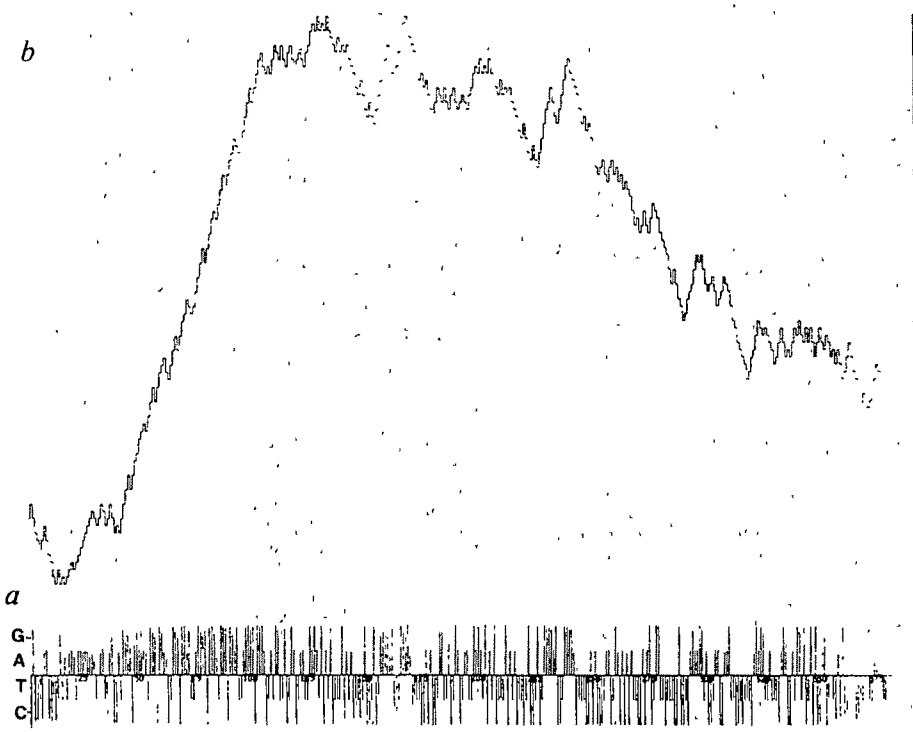

Fig. 1. The first 376 nucleotides of the SV40 genome displayed by the standard (*a*) and cumulative (*b*) line-extension formats. In both diagrams the four nucleotides G, A, T and C are given *y*-axis values of +2, +1, −1 and −2, although the scale of *b* has been reduced in this dimension. The direct 72-base pair repeat is clearly visible (region 100–250). Restriction recognition sequences form (usually) rotationally-symmetrical patterns in *a* and symmetrical peaks or troughs in *b*.

resolving oligonucleotides for nucleic acid sequencing — wandering spot[3] (Hamori) and thin-layer acrylamide gel electrophoresis[4] (our method). This superficial coincidence may reflect a limited number of possible formats.

Our first concern has been to devise a method of transferring printed sequences, using a scanning light-pen, from the printed page to an information retrieval system. Simple variants of bar-thickness identification codes were ruled out since deciphering is particularly taxing. Angle-vector methods of display such as H-curves are not inherently machine-readable although they reveal, as do plots of G/C content, features of the overall sequence profile. The base-composition curve is, to a close approximation, the first derivative of the (projected) H-curve, and as such embodies the same information. We have also examined formats which reflect the chemical structures of the four bases and which might, by comparison of non-identical recognition sequences, reveal nucleic acid–protein contact points. However, such formats were particularly difficult to interpret by eye.

We have subsequently examined a display which combines features of both the line-extension and angle-vector formats. This cumulative line extension format (which respects the extension ratios for the four bases, Fig. 1) gives similar information to that yielded by angle-vector diagrams but is less ambiguous than projected H-curves. Restriction recognition sequences appear here as symmetrical peaks. However, the format is not machine-readable and we have not proceeded further with this approach.

The two methods under discussion [1,2] meet different applications. The method we have proposed reveals local features of a DNA sequence and is limited to some 10,000 nucleotides per standard page. The display is machine-readable. In contrast, H-curves accentuate (as do G/C content plots) global features of a large-scale sequence while concealing the detail. They permit 100,000 or more nucleotides to be displayed per page. To this extent the two methods are non-overlapping and provide a visual representation of a particular nucleic acid sequence.

Powers of ten wrongly expressed

SIR — It is surprising how often authors improperly use powers of 10, in the expression of radioactivity measurements particularly. I often read manuscripts in which the ordinates are labelled as follows: 'Radioactivity (c.p.m. × 10^{-3})' or simply 'c.p.m. × 10^{-3}' with figures ranging from 0 to 10 or so.

Since $a \times b = b \times a$; 'c.p.m. × 10^{-3}' actually means '10^{-3} c.p.m' or 'milli-counts per min'. This is obviously not what the authors mean. The proper way to label such ordinates is either '10^{-3} × radioactivity (c.p.m.)' or 'Radioactivity (c.p.m. × 10^{3})'.

A physical quantity (see page 5 in ref. 1) is the product of a pure number and a unit, that is, a particular physical quantity used as a standard, for example:

Mass = 3 × grams (or 3 g) (1)
Radioactivity = 5,000 × c.p.m. (or 5,000 c.p.m.) (2)

If one divides 5,000 by 10^3 in equation (2), then 'radioactivity' should also be divided by 10^3 (or multiplied by 10^{-3}), or 'c.p.m.' should be multiplied by 10^3.

Many authors divide both the number and the unit by 10^3, thus dividing only the right-hand side of equation (2) by 10^3. This is incorrect.

Mass extinction times and correlations

SIR — Rampino and Stothers[1] make the interesting argument that the correlation they found[2] between ordered sequences of nine mass extinction times and nine galactic plane crossings ($r = 0.996$) is statistically significant, while the correlation that I found[3] between the same ordered extinction times and the first nine prime numbers ($r = 0.986$) is not. Of course, this leaves open the question of the significance of the correlation of the ordered extinction times and the first nine odd numbers ($r = 0.995$).

The question of how to test statistical relations between serial data is a serious and difficult one of long standing, going back at least a century to W. Stanley Jevons' attempts to show a connection between sunspots and the business cycle. I believe its resolution in the present case will probably require more data, and certainly a different analysis, than that given by Rampino and Stothers. All monotone series appear highly correlated, all regular monotone series appear even more so. This artefact aside, and even under the authors' most optimistic assumptions, the statistical evidence is simply too weak to reach any conclusion, due to the large variance (relative to the small sample size) of the times between mass extinction dates. The intriguing connection Rampino and Stothers suggest between these two phenomena may well be a real one; their analysis has not yet proved it to be real.

Records of Halley's comet on Babylonian tablets

F. R. Stephenson, K. K. C. Yau & H. Hunger*

Department of Physics, University of Durham, South Road, Durham DH1 3LE, UK
* Institut für Orientalistik der Universitat Wien, Universitätsstrasse 7/V, A-1010 Wien, Austria

The late Babylonian texts in the British Museum are shown to contain probable observations of Halley's comet at both its 164 BC and 87 BC apparitions. These texts have important bearing on the orbital motion of the comet in the ancient past.

HALLEY'S comet returns to the inner Solar System every 75–80 years, the precise interval depending appreciably on perturbations in its orbit induced by various planets. The comet is unique in being the only known periodic comet that regularly becomes bright enough to attract the attention of the unaided eye. As a result, no other comet has a comparable history. Since the pioneering work of Halley[1], the orbital motion has been investigated carefully and observations of every apparition as far back as 12 BC have been identified confidently[2].

Despite this impressive record, the history of Halley's comet before 12 BC is relatively obscure. At this early period, Chinese records, so detailed in later centuries, are comparatively poor, although there are two possible references in 87 BC and 240 BC[2,3]. Greek and Latin sources mention several comets occurring in ancient times, but scant attention is paid to information such as celestial location and exact date of observation. Identification of P/Halley (the prefix denotes the periodic nature of the comet) among such diverse material is very difficult, if not impossible.

A neglected source of cometary observations is the late Babylonian astronomical texts. These inscribed clay tablets were discovered about a century ago and are now mainly in the British Museum[4]. Here we present for the first time two separate Babylonian records of P/Halley from 164 BC (the only extant records of this apparition in the world) and one from 87 BC. It is hoped that these records will enable a more definite orbit of P/Halley to be traced into the ancient past and a deeper understanding of the evolution of cometary orbits to be made with respect to the recent interest in cometary catastrophism.

Orbital parameters

According to Ho Peng Yoke's[5] catalogue of oriental records of comets and guest stars, some 500 naked-eye comets have been observed over the past 2,200 years (that is, an average of one comet approximately every five years). On the basis of these statistics, there is a significant probability of another bright comet appearing in the same year as P/Halley itself; in fact several such double events are known to have occurred, most recently in 1910. Thus, it is evident that to investigate the most ancient apparitions of Halley's comet, a highly reliable orbital theory is required or an incorrect identification may well be made. Recently, four independent sets of osculating orbital elements have been derived for P/Halley by Chang[6], Yeomans and Kiang[7], Brady[8] and Landgraf[9]. All the solutions cover more than three millennia and are based on a numerical integration of the equations of motion of the comet backwards in time.

The apparent motion of a comet across the celestial sphere is only weakly dependent on small changes in orbital parameters such as eccentricity, inclination and perihelion distance. The slight differences in these parameters deduced by the various authors can safely be neglected. On the other hand, the relative motion with respect to the Earth is very sensitive to variations in the precise date of perihelion passage (T). Hence a question of prime concern is the reliability of values of T as calculated by the authors of refs 6–9.

Both telescopic and pre-telescopic measurements of the position of P/Halley enable the dates of every perihelion passage back to AD 989 to be determined accurately[2,3,7]. On only two occasions during this period do observational uncertainties exceed 0.5 day (1.5 days in AD 1222 and 0.8 days in AD 1145).

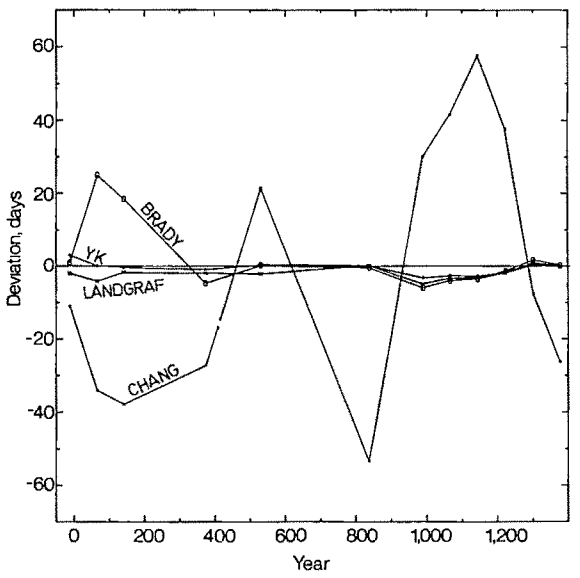

Fig. 1 Plot of the deviations between the calculated and observed dates of perihelion passage for Halley's comet between 12 BC and AD 1378 for the investigations in refs 6–9 YK, Yeomans and Kiang.

Further back in time the precision of observation is generally low but there are several notable exceptions. In AD 837, 530, 374 and 141, careful measurements of the RA of the comet by Chinese astronomers enable values of T to be deduced with uncertainties between 0.1 and 0.5 days. Finally, Chinese observations in AD 66 and 12 BC, although less accurate, still have tolerably small uncertainties of ~2 days.

Over the earlier part of this time range, the results of a comparison between observation and theory for the four investigations cited are summarized in Fig. 1. This diagram emphasizes the high accuracy of Yeomans and Kiang[7], Brady[8] and Landgraf[9] in representing observations as far back as AD 374; discrepancies in T do not exceed ~5 days at any perihelion passage since that date. Similar consistency for the three most ancient well-observed apparitions (AD 141, AD 66 and 12 BC) is obtained in refs 7, 9. However, Brady's[8] results for T are somewhat discordant in both AD 141 (~20 days error) and AD 66 (~25 days), although the accuracy is again high in 12 BC (discrepancy ~1 day). The relatively low precision of Chang's[6] solution is evident; errors of a month in T are not unusual.

The mutual discrepancies in the dates of perihelion passage as calculated in refs 6–9 back to 700 BC are shown in Fig. 2. Here, Yeomans and Kiang's data[7] have been adopted arbitrarily as the standard from which to measure deviations. From Fig. 2 it is apparent that for any apparition of P/Halley back to 87 BC the agreement between refs 7–9 is good; the maximum discord amounts to less than a month. In 164 BC and 240 BC, refs 7 and 9 still tend to support one another, discrepancies being about 15 and 40 days, respectively. However, Brady[8] deviates from these solutions by some 150 days in both cases. Beyond 240 BC, even the precise years of apparition are in dispute. The apparent lack of useful observational data before 12 BC is a serious handicap to further progress. It is hoped that our discovery

of the Babylonian records for 164 BC and 87 BC will assist in the determination of more accurate solutions in the ancient past.

Babylonian observations

The extant Babylonian cometary observations are recorded in a group of cuneiform texts called Astronomical Diaries[10]. These texts originally covered the period from ~750 BC to perhaps as late as AD 75, but only a small fraction is preserved; almost all surviving texts are now in the British Museum. The diaries contain day-by-day observations, mainly of the Moon and planets, but also of other phenomena in the sky, some of atmospheric origin[11]. Comets are mentioned in several of these diaries, the earliest known observation dating from 235 BC. Unfortunately, all contexts are broken, hence it is not possible to give a complete set of observations for the apparition of any comet.

The term used for a comet in the diaries is ṣallammu (or ṣallummu), which in other Babylonian texts can denote a phenomenon similar to a meteor or fireball[12]. No etymology of the word is known; even its reading is to some extent uncertain. A meaning 'comet' is suggested by evidence from the diaries which show the ṣallammu to remain in the sky for an extended time (several days or even weeks) so that a meteor explanation is excluded. Although a meteor interpretation cannot be excluded for some of the ṣallammu mentioned in the astrological cuneiform texts, there is no evidence to suggest anything other than a cometary identification when this term is found in the diaries.

Two apparitions of P/Halley seem to be identifiable among the records of comets in the cuneiform diaries. These can be dated confidently as 164 BC and 87 BC. For the earlier of these, two separate records are extant; although both are badly damaged, the two descriptions supplement one another. Unfortunately, only a single brief entry has survived from 87 BC, but this contains several useful details, including a single exact date.

We give below transliterations and translations of each text under the relevant year. The reference numbers preceding each transliteration give the British Museum catalogue number, relevant lines of text and, where appropriate, the location in Sachs's Late Babylonian Astronomical and Related Texts (LBAT)[4]. See page 577 for a photograph of BM 41462.

(1) 164 BC

BM 41462:16f (LBAT 380)

The comet which previously had appeared in the east in the path of Anu in the area of Pleiades and Taurus, to the west [...] and passed along in the path of Ea.

BM 41628:9′ (LBAT 378)

[...š]u-ut ^{d}BE ina KI PA 1 KÙŠ ina IGI MÚL-BABBAR 3 KÙŠ ana SI NIM x[...] [...in the path] of Ea in the region of Sagittarius, 1 cubit in front of Jupiter, 3 cubits high toward the north [...]

More observations of the comet, including precise dates, may have been recorded on these same tablets, but none are now preserved. As it is part of a monthly summary, the statement in LBAT 380 that the comet 'previously had appeared in the east' suggests an observation in a preceding lunar month.

As both tablets are badly damaged, it is difficult to assess exactly how much information is missing from the original records. In both texts, the details about the comet are contained in a summary statement at the end of a month. However, neither on BM 41462 nor on BM 41628 is the month (or even the year) preserved. Both texts must be dated by astronomical calculation using the lunar and planetary observations that are also recorded.

The obverse of BM 41462, on which the comet is reported, covers much of two consecutive months. Among the observations that are useful in dating the tablet are the following: (1) During the month in which the comet "passed along in the path of Ea", Jupiter was in Sagittarius; Venus was also in Sagittarius until the middle of the month, afterwards moving into Capricornus; Mercury was in Libra. (2) On the night of the 8th(?) of this same month, in the early evening, Venus was 1 cubit below Jupiter. (The cubit was equivalent to ~2.5°; see below.) (3) On the 14th, towards morning, the Moon was 1.5 cubits in front of β Tau and 4 cubits towards the south of this star. (4) On the 23rd, towards morning, the Moon was 1 cubit in front of γ Vir and 1.5 cubits towards the south. (5) On the 28th, in the early evening, Venus was 2.5 cubits below β Cap. (6) About the 12th of the following month, Venus was 2 fingers (that is, some 0.2°) above γ Cap, whereas towards morning Mars was above α Vir.

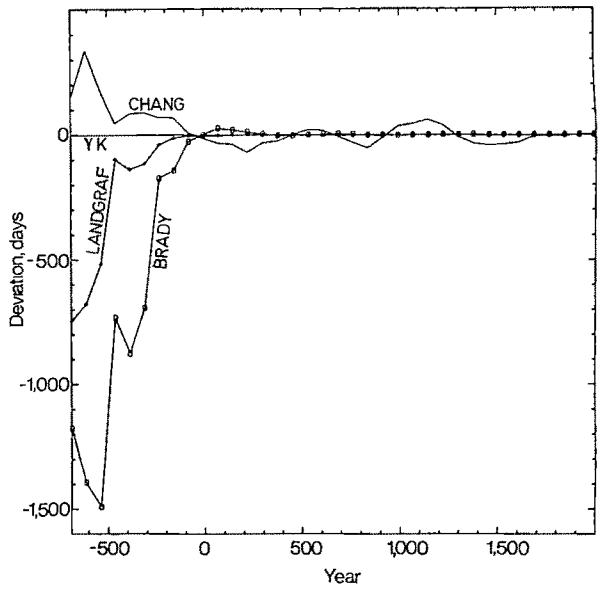

Fig. 2 Plot of the deviations between the calculated dates of perihelion passage for Halley's comet calculated in refs 6, 8, 9 relative to the results of Yeomans and Kiang[7] for the period since 700 BC. YK, Yeomans and Kiang.

On both this tablet and BM 41628, the abbreviations used for the names of stars indicate a date of writing well after 400 BC. No diaries are known later than 40 BC and we have thus limited our investigation to the period between 400 BC and the beginning of the Christian Era. During this time, the only date that satisfies the various astronomical data is the lunar month beginning on 21 October (Julian calendar) in 164 BC. From the tables of Parker and Dubberstein[13], this is equivalent to month VIII of the year 148 of the Seleucid calendar (that is, SE 148).

The tablet catalogued as BM 41628 is much more extensively damaged than BM 41462. Its obverse again covers portions of two consecutive months, but most of the entries are fragmentary. Nevertheless, several lunar and planetary observations have survived intact. These include: (1) During the month in which the comet was recorded, Saturn was in Scorpius, Mars was in Virgo and, as the cometary text states, Jupiter was in Sagittarius. (2) On the 11th of the same month. Saturn set heliacally in the end of Scorpius. (3) On the 18th, Mercury set heliacally in the east in Scorpius. (4) On the 11th of the next month, at the beginning of the night, the Moon was 1 cubit in front of α Tau and 1 cubit towards the north. (5) About the 12th of this month, Venus was 2 fingers above γ Cap. (See also entry (6) under BM 41462.)

Calculation of these observations leads to precisely the same date, the lunar month beginning on 21 October in 164 BC.

As well as dating the two texts separately, it is important to examine the direct evidence that both tablets share a common date. On each obverse the following duplicate observations are found: (1) Towards the end of the lunar month in which the comet is mentioned, the time interval between moonrise and sunrise at last visibility of the crescent Moon is given as 23,4C

uš (that is, 23.7° or ~95 min). (2) Attention has already been drawn to the observation on about the 12th of the following month when Venus was 2 fingers above γ Cap.

On the reverse of both tablets there are several identical pairs of observations, both covering two successive months: (1) On the 7th of the second month cited, both texts state that at the beginning of the night the Moon was 2/3 cubit behind β Gem. (2) On the 9th, both texts assert that at the beginning of the night the Moon was 6.5 cubits below ε Leo. (3) On the 15th, in each case the interval between sunrise and moonset is given as 5,30 uš (that is, 5.5° or 22 min). (4) As well as the above, on about the 15th of the month a lunar eclipse is reported. The two texts give few overlapping details but a separate tablet giving fuller information (BM 34037) shows that they represent portions of the same eclipse record.

The evidence is thus conclusive that the two tablets represent copies, albeit with slight variants, of the same astronomical diary. Many similar duplicate and some triplicate texts are known.

(2) 87 BC

BM 41018 rev. 8′–10′ (unpublished)

[...GE$_6$]13(?) 8 ME muš USAN ^{d}ṣal-lam-mu-ú

[...] šá ITÚ.ŠU u$_4$-mu al-la u$_4$-mu 1 KUŠ

[...] x bi-rit SI u MAR mi-ši-iḫ-šú 4 KÙŠ

On the 13th(?), the interval between moonrise and sunset was 8 degrees, measured; first part of the night, a comet [...] which in month IV day beyond day, one cubit [...] between north and west its tail 4 cubits [...]

As indicated by the brackets, the test is fragmentary. The gaps at the beginning of each line may be rather long. The passage quoted is from the 13th(?) (the number is damaged, but certainly it is at least the 12th) day of a month. Although, as before, neither the month nor the year are preserved, both may be derived uniquely from other astronomical data recorded on the same tablet. This information includes: (1) 3rd day of the same month, the Moon was 2 cubits east of Venus; (2) on about the 4th day, Mercury set in the east in Leo; (3) some time between the 4th and 12th Mars was 6 fingers above δ Cnc; (4) 13th day, a lunar eclipse which "passed by", that is, a predicted eclipse which was invisible in the longitude of Babylon; (5) some time between the 13th and 19th, Venus was 1 cubit below α Lib.

The reverse of the text mentions the capital city of Seleucia, founded in 274 BC, which sets a useful time limit. The only astronomically acceptable date is the lunar month beginning on 12 August in 87 BC, that is, month V of the year SE 225. This date is confirmed by the retrospective entry relating to month IV in the account of the comet. Calculation of the time interval between moonrise and sunset on the evening of the cometary observation (that is, 8° or 32 min) determines the date as 24 August, corresponding to the 13th of the lunar month[13]. The fact that the entry for a specific day summarizes observations going back to the previous month strongly suggests that on this day the comet had either reappeared after a period of invisibility or had been seen for the last time.

Because of the gaps in the text, one cannot be definite about certain points of syntax. Thus 'one cubit' may refer to the average daily motion of the comet or it may relate to a verb in the missing part of the next line. However, given the standard presentation of Babylonian observations in which the time reference precedes statements of position or movement, it seems probable that the present passage describes the average daily movement of the comet. The term mishu, which occasionally refers to some luminous phenomenon associated with stars, here seems to indicate the tail of the comet; passages in other texts show that it is usual to specify its direction, as indicated here.

The 'cubit', mentioned in two of the three texts, was used in Babylonian astronomy as an angular unit. It is usually estimated to be ~2° (ref. 14). From an analysis of some 20 Babylonian observations of conjunctions of the Moon with stars contained in a diary dating from SE 60 (=252 BC)[14], we have arrived at the result that 1 cubit = 2.5 ± 0.5° (s.d. per observation). The analysis also indicates that the term ina IGI ('in front of') used in the second of the 164-BC texts was a standard expression meaning 'to the west of', implying an earlier meridian transit.

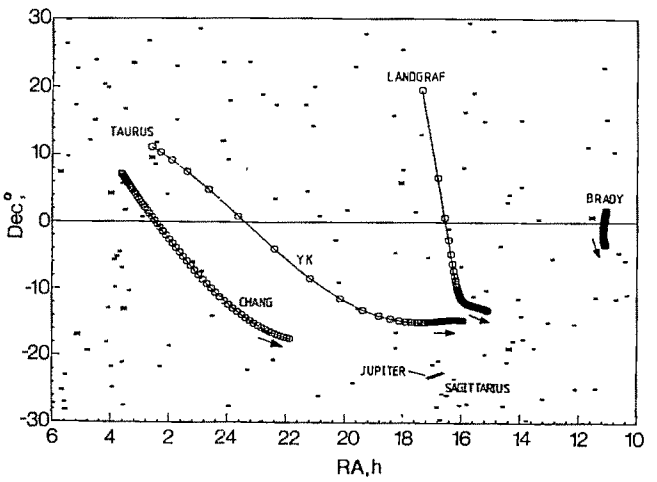

Fig. 3 The computed motion of Halley's comet in 164 BC between 22 Sep and 19 Nov for the dates of perihelion passage deduced by Brady[8] (164 BC 22 June), Landgraf[9] (164 BC 30 Oct), YK (Yeomans and Kiang)[7] (164 BC 12 Nov) and Chang[6] (163 BC 20 Jan). Positions are at daily intervals. Background stars down to mag +3.5 are shown.

The Babylonians divided the sky into three regions of declination named after gods: Enlil, Anu and Ea[15]. Of these, Anu was the equatorial region, extending between about +17° and −17°. The entire sky further north was known as Enlil, whereas that to the south was Ea. The limiting declination was based on the well known text ^{mul}APIN (possibly composed ~1000 BC), which states that the Sun spent exactly one quarter of a year in each of these regions before moving on to the adjacent one. However, it would perhaps be unwise to assume too precise a definition of Anu and Ea in analysing the motion of the comet.

Analysis of 164 BC observation

There is a brief Chinese record of a comet on a date equivalent to 6 February 162 BC (ref. 5), but this is much too late for Halley's comet. The dates of perihelion for P/Halley as computed in refs 6–9 all lie between June 164 BC and January 163 BC. The salient points of the two Babylonian accounts are as follows: (1) First appearance in the east in the Taurus region, some time before month VIII (21 October to 19 November). (2) Further appearance in the west in Sagittarius during month VIII. (3) As the difference in RA between Taurus and Sagittarius is as much as 14 h in the direct sense, it seems probable that the motion of the comet was retrograde. (4) The position relative to Jupiter (then in Sagittarius, according to calculation) was recorded at some time between 21 October and 19 November (the Babylonian month VIII). The fact that a difference in longitude (some 2.5°), as well as latitude is mentioned, indicates that this is not a record of closest approach. The reason for recording this rather careful measurement is obscure.

Figure 3 is a chart of the sky in the range of RA from 10 to 6 h and dec. from +30° to −30° at the epoch 164 BC. The region of Taurus (where the comet seems to have been first observed) and Sagittarius (where it was later observed) are marked. The range of positions computed from the JPL Ephemeris DE102 (ref. 16) for Jupiter during month VIII is indicated by crosses. The four roughly vertical tracks (composed of small squares) denote the computed motion of Halley's comet during months VII and VIII (22 September–19 November) on each of the dates of perihelion passage deduced by Brady (22 June), Landgraf (30 October), Yeomans and Kiang (12 November), all in 164 BC, and Chang[6] (20 January 163 BC). In each case the general direction of travel is from north to south, the individual squares representing positions of the comet at daily intervals. Only on the solution of Yeomans and Kiang[7] does the computed path approximate to the observational record. It is evident that merely

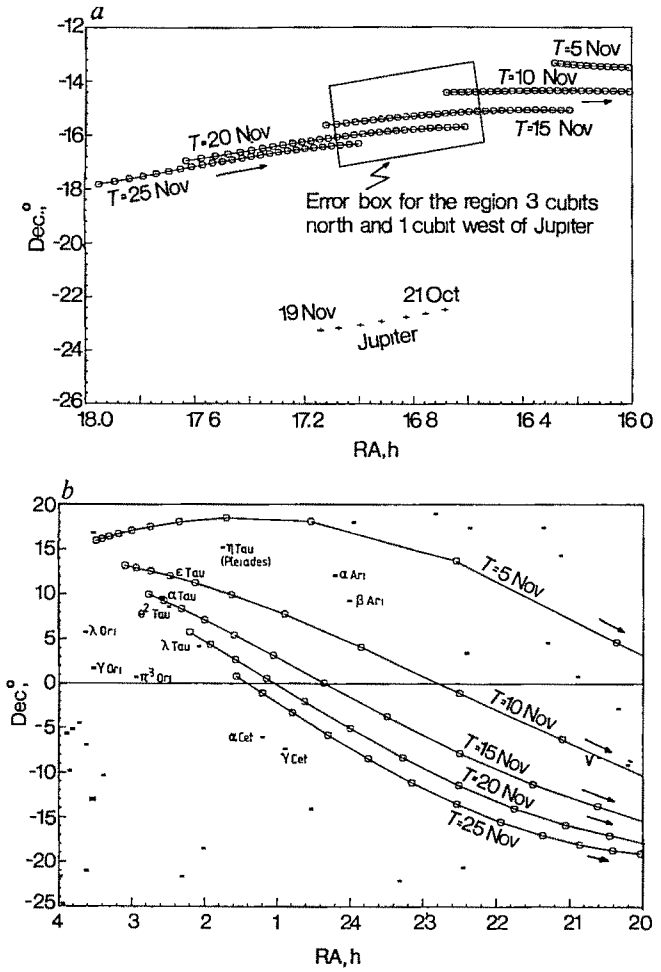

Fig. 4 *a*, Computed paths of Halley's comet in 164 BC between 21 Oct and 19 Nov (month VIII) for dates of perihelion (T) between 5 Nov and 25 Nov. The motion of Jupiter in this interval is shown and also the region of sky 3 cubits (7.5 ± 1.5°) north and 1 cubit (2.5 ± 0.5°) west of the planet as observed by the Babylonians. *b*, Computed paths of Halley's comet in 164 BC from first visibility for T between 5 Nov and 25 Nov. Stars in the Taurus region, where the comet appeared, are labelled.

varying the date of perihelion passage of Halley's comet can achieve a highly satisfactory representation of the observed motion, including the close approach to Jupiter whilst in Sagittarius. In our opinion, this is sufficient grounds for a firm identification of the recorded comet with P/Halley.

Because Halley's comet passed unusually close to the Earth (some 0.1 AU for the date of perihelion deduced by Yeomans and Kiang), small changes in T appreciably alter the relative motion of the two bodies. This circumstance is helpful in fixing narrow limits to the range of dates over which the perihelion can actually lie. We shall first consider the close approach to Jupiter during month VIII (21 October–19 November).

Figure 4*a* covers the region of sky from RA 16 to 18 h and dec. −12° to −26° at 164 BC. The computed motion of Jupiter (eastwards) during month VIII and the region 3 cubits (7.5 ± 1.5°) north and 1 cubit (2.5 ± 0.5°) west of the planet are shown. Following Babylonian practice, the relative positions of comet and planet are assumed to be measured on the ecliptic system, but there would be little difference if an equatorial frame had been used.

Computed tracks of Halley's comet moving from east to west during month VIII are shown in Fig. 4*a* for the following dates of perihelion: Nov. 5, 10, 15, 20 and 25 (each at 0 h ET). To agree with observation, some part of the computed path of the comet should intersect the error box. The indicated range of T is thus between 9 and 26 November. If T is altered by one day, the resultant east–west displacement of P/Halley is some 1.2° so that any observational error in the relative position of the comet and Jupiter can probably be neglected. It seems probable that the original tablet would record the precise date of conjunction with Jupiter and it is regrettable that because of the loss of this information only a range of T covering 17 days can be deduced. Nevertheless, this is much smaller than the scatter among the various dates derived from numerical integration.

As mentioned earlier, Jupiter was only a little to the east of the Sun during month VIII and the visibility of the comet needs to be considered. Based on our investigation of Chinese observations of the heliacal setting of P/Halley (see below under the analysis of the 87 BC record) we conclude that the comet should have been visible to the unaided eye whilst near the marked region. Hence it is not possible to restrict further the range of T on the grounds of limited visibility.

The observation made "in the east ... in the area of Pleiades and Taurus" is less accurate but gives an independent result. The precise date is no longer extant but it must be earlier than month VIII. Far-eastern records indicate that Halley's comet rarely remains visible to the unaided eye for >50 days so that first sighting is unlikely to have been earlier than month VI. During months VI and VII, Taurus would be high in the eastern sky at about midnight and the comet would thus be well placed for viewing in a dark sky. Figure 4*b* is a chart of the sky in the range RA 20 to 4 h and dec. −25° to +20°. For each of the following dates of perihelion: 5, 10, 15, 20 and 25 November, the computed motion of Halley's comet is shown. The individual tracks begin with the location of the comet at what we infer to be its earliest probable date of discovery. We have investigated the discovery magnitude of P/Halley throughout much of its history using some 20 dates of first sighting reported in various far-eastern records. From the empirical formula of Morris and Green[17], based on the observations in 1910, we find that the comet is seldom detected with the unaided eye even in a dark sky until it becomes fairly bright, between about +3.5 and +4 mag. (There is only a single instance of discovery when the calculated magnitude was fainter than +4, that is, +4.3 mag in 12 BC.) This is, of course, well above the threshold brightness for the eye (around +6 mag) but these early observers, unlike their modern counterparts, had no advance warning. We have thus assumed a discovery magnitude of +4 at Babylon in 164 BC.

Before attempting to refine the range of T already deduced, the identification of MÚL-MÚL (rendered above as Pleiades) and MÚL.GU$_4$-AN-NA (Taurus) must be considered. The modern equivalents of the various Babylonian star groups have been investigated in detail by Kugler[18], Schaumberger[15], Gössmann[19] and, more recently, Reiner[20]. From these works it is apparent that MÚL-MÚL ('The Stars') was identical to the Pleiades group whereas MÚL.GU$_4$-AN-NA ('The Bull of Anu') was centred on α Tau and the Hyades.

From the close approach to Jupiter, a date of perihelion passage for Halley's comet between 9 and 26 November has already been derived. Referring to Fig. 4*b*, it is not possible to use the Pleiades/Taurus observation to refine the earlier of these two limits, as for any T between about 7 and 16 November P/Halley would pass directly between η Tau and α Tau/Hyades. However, for dates of perihelion after about 24 November, the comet would probably not be noticed until it had moved into Cetus (MÚL-IKU). Hence we can now place firm limits on the date of perihelion for Halley's comet in 164 BC between 9 and 26 November, the latter limit possibly being as early as 24 November.

Analysis of 87 BC observation

Apart from the Babylonian text, there is a brief Chinese report of a comet appearing during this year which may relate to P/Halley[2,3]. However, only the month and general area of sky in which the comet appeared are given and we shall not consider this observation further. It is unfortunate that the cuneiform record is also brief. Despite this, several important deductions can be made. These may be summarized as follows: (1) As suggested above, there are good reasons for believing that the

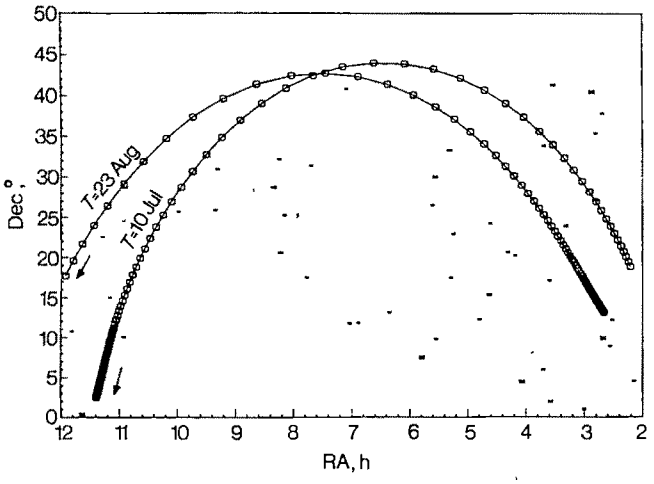

Fig. 5 The computed motion of Halley's comet in 87 BC for both the lower and upper limits of the theoretical T, that is 10 Jul (ref. 8) and 23 Aug (ref. 9) over the time range 13 Jun to 9 Sep (months III–V).

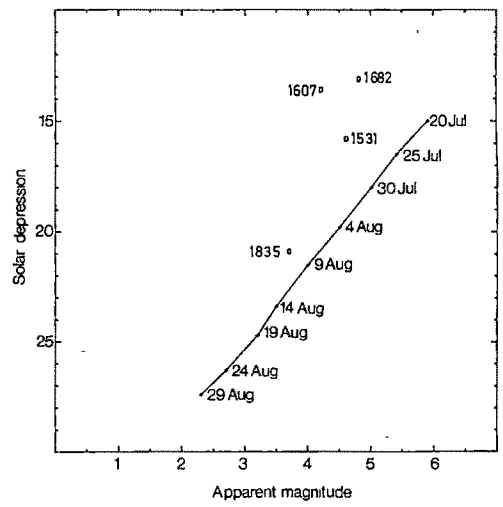

Fig. 6 Plot of the solar depression as a function of the calculated apparent magnitude of P/Halley on the evening of 24 Aug in 87 BC for dates of perihelion between 20 Jul and 29 Aug with, for comparison, the circumstances at the last recorded visibility (in Korea) in AD 1531, 1607, 1682, 1835.

observation reported on 24 August represented either reappearance or last visibility. Such a circumstance is unlikely to result from unfavourable weather, for during the summer months the skies are almost cloudless in this part of the world. (2) The comet was seen 'day beyond day' (u_4-mu al-la u_4-mu) during the 4th lunar month (14 July–11 August), which seems to imply a lengthy period of visibility during this month. (3) We add that the probability of our text referring to P/Halley, rather than some other comet, is high. The various computed dates of perihelion passage lie in the range 10 July–23 August. Calculation shows that on any of these solutions, Halley's comet would be well placed for northern observers during the summer of 87 BC (Fig. 5) and fairly bright, approaching 0 mag according to the formula of Morris and Green[17].

Figure 5 shows the computed motion of Halley's comet in a general easterly direction during months III, IV and V (13 June–9 September) in 87 BC on the dates of perihelion computed by Brady[8] (10 July) and Landgraf[9] (23 August). These represent the extreme calculated dates; Yeomans and Kiang[7] deduced 6 August, whereas Chang[6] gave 15 August. For any of these values of T, the comet never approached very close to the Earth (minimum distance ~0.45 AU) so that the motion was unusually regular. The calculated daily motion, indicated by small squares on the diagram, was always $>1°$ and $<6°$ for at least a month. As both of these values are within about a factor of two of 1 cubit, this seems to explain the reference to this quantity in the text, that is, 'day beyond day one cubit'.

As the displacement in the position of P/Halley in response to a change in T was fairly linear, it is possible to summarize the main characteristics of the apparent motion almost independently of the precise date of perihelion. On any of the four solutions cited, the comet would first reach the estimated limiting discovery brightness (+4 mag) while some 45° west of the Sun. It would then be fairly high in the eastern sky before dawn. Moving quickly eastwards, the comet would pass conjunction with the Sun approximately 10–15 days later, now becoming an evening object. Gradually diminishing in speed, it would reach a maximum elongation of only ~35° east of the Sun after a further 15 days or so. Some time later the comet, approaching a second conjunction with the Sun and growing progressively fainter, would probably set heliacally, being lost to view in the evening twilight.

From the above outline, it is apparent that the Babylonian record indicates observations both before and after the first conjunction with the Sun. The tail could only have pointed north-west before this conjunction. However, on 24 August, the date of the preserved diary entry, the comet was said to be visible in the "first part of the night" and thus to the east of the Sun. (The Babylonian astronomers divided the interval between sunset and sunrise into three roughly equal parts.) On the basis of brightness considerations, it can be deduced that by 24 August Halley's comet was probably well past conjunction with the Sun. For the comet to have been just emerging after conjunction would require an estimated discovery date (+4 mag) no earlier than about 13 August. As month IV ended on 11 August and the computed magnitude was changing by about 0.2 daily, there would seem to be no possibility of observation 'day beyond day' during this month under these circumstances. Thus, we infer that the most probable interpretation of the observation on 24 August is final visibility.

Before analysing the 24 August observation, we note that it is possible to fix useful limits on the date of perihelion in 87 BC from the additional information supplied in the Babylonian record. For T before about 20 July, the tail of Halley's comet could only have pointed north-west earlier than month IV, but such an early date does not seem to be implied in the text. If T was after about 30 August, the period of visibility in month IV would probably be too short to be described as 'day beyond day'. These limits may be narrowed further on the assumption of last sighting on 24 August.

Figure 6 illustrates the circumstances relating to the visibility of P/Halley on the evening of 24 August in 87 BC for dates of perihelion between 20 July and 29 August. The abscissa gives the apparent magnitude of the comet as deduced from the empirical formula of Morris and Green[17]. The ordinate is the depression of the Sun below the western horizon at the moment when the nucleus of the comet set (refraction being ignored). For the earlier dates of perihelion, the comet would set in strong twilight. The best time for observation would then be roughly midway between sunset and the setting of the comet itself, when the effects of the twilight glow and atmospheric absorption were optimized (although the tail would then be pointing in a roughly vertical direction, it would be very short on account of the comet's considerable distance from the Earth, some 1.5 AU for T before about 1 August).

The precise date of heliacal setting for a celestial body depends on various factors (largely of atmospheric origin) and is therefore best treated empirically. To provide some parallel data, we have analysed several dates of the last sighting of P/Halley as reported in far Eastern history. Such information is fairly regularly available over the past two millennia but before ~AD 1400 only summary records are now extant. Thus, there is a distinct possibility of copying errors, but for later centuries detailed chronicles are available from both China and Korea. The Korean works are particularly useful for our purpose because they contain day-to-day reports of astronomical phenomena, usually

stating when cloud prevented observation. Calculations based on the accurately known dates of perihelion at this relatively late period enable several instances of heliacal setting to be identified. The dates of these are 1835 November 17, 1682 October 7, 1607 November 7 and 1531 September 15. In each case the computed magnitude and solar depression are plotted in Fig. 6 (represented by circles).

Reference to Fig. 6 shows that there is some scatter among the Korean data, the 1835 solution lying somewhat below the others. The most probable explanation involves variations in the intrinsic brightness of Halley's comet from one apparition to the next, although the oriental records of first visibility show no significant long-term trends[21]. It is not possible to make any accurate deductions regarding perihelion in 87 BC, but the following remarks seem relevant: (1) Unless Halley's comet was unusually bright in 87 BC, the date of perihelion is unlikely to have been before about 25 July. For earlier dates the computed magnitude on 24 August was close to the normal limit for the unaided eye while atmospheric absorption (some 1.5 mag at optimum visibility) and the twilight glow would probably reduce the brightness well below the visual threshold. (2) For dates of perihelion after about 15 August both the calculated apparent magnitude and solar depression were very favourable and there should have been no difficulty in observing the comet on 24 August.

In summary, we infer a likely date of perihelion in 87 BC between about 25 July and 15 August. If we have misinterpreted the nature of the observation on 24 August, the latter limit would, of course, be invalid and perihelion might then lie anywhere between 25 July (to render the comet visible at all on the recorded date) and the end of August. However, the mere fact that in a day-to-day diary covering (originally) several months the Babylonian astronomers felt it sufficiently importa to provide a detailed retrospective entry on a specific day (2 August) seems consistent with an abrupt change in the visibili of the comet at that time; this we have presumed to be heliac setting.

Conclusions

We believe that the evidence that Halley's comet was observ in Babylon at its apparitions in both 164 and 87 BC is convincin The records, although badly damaged, enable fairly narro limits to be placed on the dates of perihelion in both yea between about 9 and 24 November in 164 BC and between abo 25 July and 15 August in 87 BC. Of the four numerical integr tions investigated here, only that of Yeomans and Kiang[7] pr vides acceptable dates of perihelion in both years. This presur ably results from the incorporation in their solution of sever rather accurate ancient and medieval observations, rather th using a purely theoretical analysis. In particular, their identific tion of a brief Chinese record in 240 BC as the most ancie reliable sighting of the comet finds support here. The Babyloni observations may prove useful in the integration of the moti of P/Halley further backwards in time, possibly leading to t recognition of still earlier records of this most famous of comets.

We thank Mr C. B. F. Walker of the Department of Weste Asiatic Antiquities, British Museum and Professor A. Wolfendale FRS, Department of Physics, University of Durha for reading this paper and offering several valuable suggestion The original deciphering and identification of the Babyloni texts investigated here was the work of the late Professor A. Sachs, Brown University, USA and this paper is dedicated his memory.

The products of six unidentified reading frames of human mitochondrial DNA are precipitated from a mitochondrial lysa by antibodies against highly purified native beef heart NADH-ubiquinone oxidoreductase (complex I). These produc are enriched greatly in a human submitochondrial fraction enriched in NADH-Q_1 and NADH-$K_3Fe(CN)_6$ oxidoreducta activities. We conclude that the six reading frames encode components of the respiratory-chain NADH dehydrogenase.

ONE of the most remarkable findings from the sequence analysis of mitochondrial DNAs from several mammalian sources[1-4], *Xenopus laevis* (B. Roe, personal communication) and *Drosophila* species[5-7] has been the discovery that more than ha of the informational content of animal mtDNA resides in eig unidentified reading frames (URFs). These genes, with o

exception, have no obvious amino-acid sequence homology to any yeast mtDNA reading frames. The demonstration that URFs with partial homology to several of the mammalian mtDNA URFs occur in mtDNA from other lower eukaryotic organisms, as first observed in *Aspergillus nidulans*[8,9] and then in *Neurospora crassa*[9] and protozoa[10,11], strongly supported the idea that these URFs code for functional proteins. Direct evidence that the URFs are functional genes has been provided by the identification of translation products corresponding to most of the human URFs, achieved by the use of antibodies directed against peptides predicted from the DNA sequence. This approach has led to the identification of the polypeptides encoded in URFA6L (ref. 12), URF1 (ref. 13), URF3 (ref. 13), URF2, URF4 and URF4L (P.M., A.C., M. Riley, B. Cottrell, R.F.D. and G.A., in preparation).

Little has been discovered about the physiological role of mtDNA URF products from animal and other species. The product of the smallest URF, URFA6L, has a low but significant amino-acid sequence homology and other structural similarities[14,15] to the product of a newly identified yeast mtDNA gene (*aap1*)[14], which seems to be a component (subunit 8) essential for the assembly of a functional H^+-ATPase complex; these observations have suggested that the URFA6L product is associated with the mitochondrial H^+-ATPase[14,15]. The other URF products are hydrophobic proteins[16] and, therefore, are presumably associated with the inner mitochondrial membrane. Among the enzyme complexes of this membrane, the NADH–ubiquinone oxidoreductase (complex I, ref. 17) and the succinate–ubiquinone oxidoreductase (complex II, ref. 18) seemed to be good candidates for containing some of the URF products, despite the previous failure to detect mitochondrially synthesized polypeptides in NADH–ubiquinone oxidoreductase of rat source[19]. The NADH–ubiquinone oxidoreductase (hereafter referred to as respiratory-chain NADH dehydrogenase or complex I) was of particular interest because it consists of a shell of $\geqslant 15$ hydrophobic polypeptides surrounding a core containing the low-relative molecular mass (M_r) NADH dehydrogenase or flavoprotein fragment and the iron–protein fragment[20,21]. Here we describe immunoprecipitation experiments using antibodies raised against purified beef heart complex I or against synthetic peptides predicted from the human URF sequences and enzyme fractionation studies; the results of the three approaches strongly suggest that the products of six of the human URFs, URF1, URF2, URF3, URF4, URF4L and URF5, are components of the respiratory-chain NADH dehydrogenase.

Products of mitochondrial genes

Figure 1 shows the present status of the polypeptide assignment to the reading frames of human mtDNA. Most of these assignments have been made by the use of anti-peptide antibodies; cytochrome *c* oxidase subunits I, II and III (COI, COII and COIII) and cytochrome *b* have been identified by analysis of the site of synthesis and electrophoretic properties of the subunits of purified human cytochrome *c* oxidase complex[22] and, respectively, purified human cytochrome b–c_1 complex (C.-J. Doersen and G.A., in preparation). The mitochondrially synthesized component 1 ($M_r \sim 51{,}000$; ref. 23) has been identified tentatively as the product of URF5 (expected $M_r = 66{,}600$; ref. 1), because this is the only gene that could code for such a large polypeptide. The discrepancy between the expected and the estimated size can be explained by the well-known bias in size estimates based on SDS-polyacrylamide gel electrophoresis of mtDNA-encoded hydrophobic proteins[12,13]. Thus, it seems that the main translation products of the human mitochondrial genes have been identified.

Reaction with anti-peptide antibodies

To determine whether the URF products are part of a protein complex, several individual URF-specific anti-peptide antisera were tested on a Triton X-100 HeLa cell mitochondrial lysate; it seemed possible that at least some of the antigenic peptides in such a complex would be accessible to their respective antibodies. Indeed, we found that each antiserum tested had a tendency to precipitate other URF products as well as the polypeptide against which it had been raised. This was seen most clearly with an antiserum against the carboxy-terminal heptapeptide of the URF4L product (anti-URF4L-C). This antiserum precipitated only one component, component 26, from an SDS mitochondrial lysate (Fig. 2*a*), which represents the URF product against which it had been prepared (P.M. *et al.*, in preparation). In striking contrast, the same antiserum precipitated components 1 (URF5), 4 and/or 5 (URF4), 11 (URF2), 12 (URF1) and 24 (URF3) as well as component 26 from Triton X-100 mitochondrial lysate (Fig. 2*b*). The same phenomenon was observed with an antiserum against the carboxy-terminal nonapeptide of the URF4 product (anti-URF4-C) (Fig. 2*a*, *b*) and with anti-URF2-N and anti-URF3-C antisera (not shown); each of these antisera precipitated its respective polypeptide, as well as a small amount of the other five URF products of the group specified above.

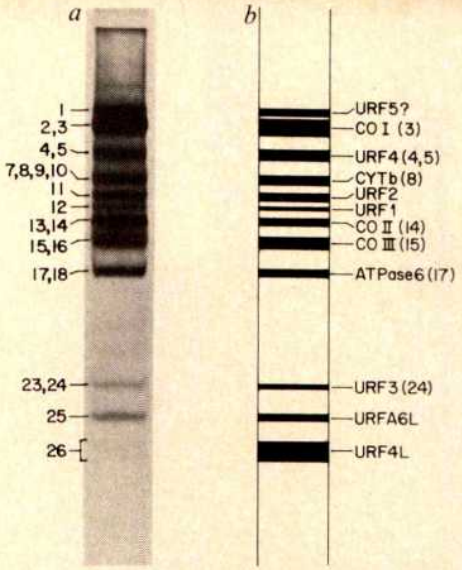

Fig. 1 Polypeptide assignment to the human mitochondrial genes. *a*, Electrophoretic pattern in an SDS/urea-polyacrylamide gel of the HeLa cell mitochondrial translation products labelled *in vivo* with ^{35}S-methionine in the presence of 100 μg ml^{-1} emetine and numbered according to Ching and Attardi[23]. *b*, Pattern of the polypeptides assigned to individual reading frames of human mtDNA. Anti-peptide antibodies were used for the polypeptide assignment to URF1, URF3, URFA6L, ATPase 6 (refs 12, 13), URF2, URF4 and URF4L (P.M. *et al.*, in preparation); the polypeptides corresponding to COI, COII and COIII were identified by analysis of the subunits of purified human cytochrome *c* oxidase[22], and the product of the cytochrome *b* gene by analysis of the subunits of purified cytochrome b–c_1 complex (C.-J. Doersen and G.A., in preparation). Numbers in parentheses indicate the polypeptide within each multicomponent band that corresponds to the indicated reading frame.

All immunoprecipitates produced from a Triton X-100 lysate by anti-URF4, URF4L, URF2 and URF3 antibodies exhibited a variable, generally relatively small amount of cytochrome *c* oxidase subunits I, II and III, but we did not detect cytochrome *b* or ATPase subunits 6 and 8 (URFA6L product). It seems probable that the presence of cytochrome *c* oxidase subunits in the specific precipitates reflects an incomplete dissociation or a secondary aggregation of these subunits in the experimental conditions used here. Even so, the tendency of the products of URFs 1, 2, 3, 4, 4L and 5 to be co-precipitated by the individual anti-peptide antibodies suggested that these components are associated with each other in some kind of complex.

Reaction with anti-complex I antibodies

To test the possibility that the putative complex containing URF1, URF2, URF3, URF4, URF4L and URF5 products is the respiratory-chain NADH dehydrogenase (complex I), we used

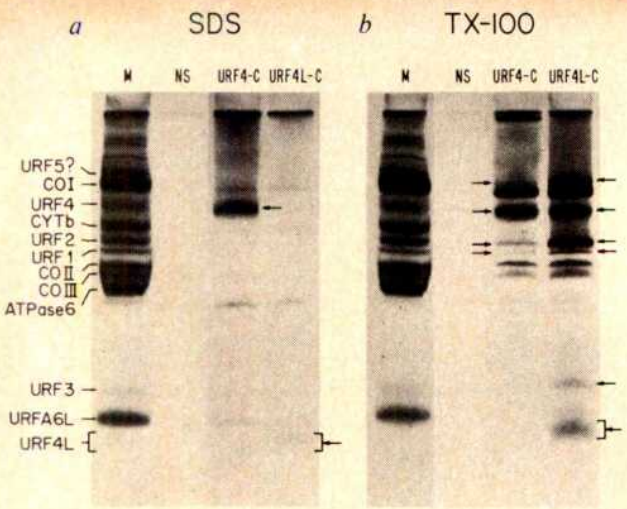

Fig. 2 Co-precipitation of several URF products by individual URF-specific antipeptide antisera. Shown are fluorograms, after electrophoresis through SDS/urea-polyacrylamide gels, of HeLa cell mitochondrial translation products immunoprecipitated by antibodies against peptides corresponding to specific regions of URF4 and URF4L. γ-Globulins from antisera against the carboxy-terminal nonapeptide of the URF4 product (URF4-C) or the carboxy-terminal heptapeptide of the URF4L product (URF4L-C) or from normal serum (NS) were incubated with an SDS lysate (*a*) or a 0.5% Triton X-100 (TX-100) lysate (*b*) of ^{35}S-methionine-labelled mitochondria. M, Pattern of mitochondrial translation products.

Methods. Antisera were prepared as described elsewhere (ref. 12 and P.M. *et al.*, in preparation). A γ-globulin fraction, free of anti-bovine serum albumin antibodies[12], was used in these experiments. For the selective labelling of the mitochondrial translation products, HeLa cells grown for 22 h in the presence of 40 μg ml^{-1} chloramphenicol[27] were labelled with ^{35}S-methionine (1,040 Ci mmol^{-1}; 19 μCi ml^{-1}) for 2 h in the presence of 100 μg ml^{-1} cycloheximide in methionine-free medium supplemented with 5% dialysed calf serum, then pelleted, washed once in complete medium, resuspended in the same medium at 10^5 cells per ml, and incubated for an additional 18 h. The mitochondrial fraction was prepared as described previously[12]. *a*, An SDS lysate of the mitochondrial fraction was prepared and aliquots (2×10^5 c.p.m., 220 μg) were immunoprecipitated at room temperature with 250 μg of γ-globulins from each of the antisera or from NS by a modification of the previously described procedure[12], to be described in detail elsewhere (P.M. *et al.*, in preparation). The immunoprecipitated products were run on an SDS/urea-polyacrylamide gel[12]. *b*, For immunoprecipitation of intact complexes of the inner mitochondrial membrane, all operations were carried out at 4 °C. Samples of mitochondrial suspension (2×10^5 c.p.m., 220 μg) were resuspended in 50 μl 0.005 M Tris-HCl, *p*H 6.7 (25 °C), 0.002 M methionine, 0.001 M phenylmethylsulphonyl fluoride, 0.5% (w/v) Triton X-100, at a concentration of 5 mg protein ml^{-1} and incubated for 20 min. After diluting the samples fourfold with the same solution containing 1 mg ml^{-1} ovalbumin (incubation buffer), methanol was added to 2% and the mixtures incubated for a further 10 min. After addition to each sample of 125 μl formaldehyde-fixed *Staphylococcus aureus*, Cowan strain I suspension (Zysorbin, Zymed), prewashed with and suspended in incubation buffer, the mixtures were incubated for 30 min and then centrifuged in an Eppendorf microfuge for 2 min. To each supernatant, 70 μl incubation buffer and 250 μg γ-globulin fraction in 70 μl phosphate-buffered saline were added and the mixtures incubated for 1 h. After addition of a 10-fold protein excess of a 0.5% Triton X-100 mitochondrial lysate (12.5 mg ml^{-1}) from unlabelled cells and SDS to 0.1%, the samples were mixed with 125 μl Zysorbin suspension, incubated for 30 min and centrifuged in the microfuge for 2 min. The pellets were washed by centrifugation once with incubation buffer containing 0.1% SDS, once with incubation buffer and once with 0.010 M Tris-HCl, *p*H 6.7 and then extracted with 60 μl 8 M urea, 4% SDS, 0.01 M Tris-HCl, *p*H 7.4, 0.1% β-mercaptoethanol for 30 min at 37 °C and 10 min at 50 °C. The extracts were run on an SDS/urea-polyacrylamide gel.

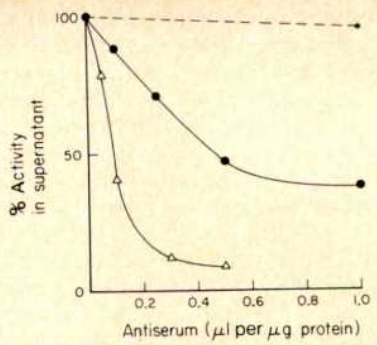

Fig. 3 Immunoprecipitation of complex I from solubilized human kidney submitochondrial particles by antiserum 1 against native beef heart complex I. ●, Antiserum tested on human kidney submitochondrial particles; △, antiserum tested on beef heart submitochondrial particles; ⋆, normal serum tested on human material.

Methods. Submitochondrial particles were prepared from human kidney or beef heart mitochondria and solubilized with 0.5% Na-DOC in the presence of 0.5 M KCl, as described previously[25]. After centrifugation in the 10 × 10 ml rotor of an MSE 65 centrifuge at 25,000 r.p.m. for 40 min, the supernatant was incubated at 4 °C overnight in the presence of 1% Triton X-100. After another centrifugation as above, portions of the supernatant (50 μg protein in 50 μl) were incubated for 1 h at 4 °C with the indicated volumes of antiserum 1 against beef heart complex I or normal serum (with addition of Triton X-100 to a final concentration of 1%). Samples were assayed for NADH-$K_3Fe(CN)_6$ oxidoreductase activity[25] after centrifugation in the conditions described above.

rabbit antisera raised against highly purified native bovine complex I (ref. 24). One such antiserum (antiserum 1) could precipitate ~60% of the NADH-$K_3Fe(CN)_6$ oxidoreductase activity from deoxycholate- and Triton X-100-solubilized human kidney-submitochondrial particles (Fig. 3). The non-precipitated enzyme activity results from an unrelated enzyme with different kinetic properties[25,26] which is more abundant in the kidney (40–50%) than in the heart (10–20%) (C.I.R., unpublished observations). Electrophoretic analysis of the immunoprecipitated human kidney complex I on a 12–16% polyacrylamide gel, in parallel with the beef heart complex I, revealed a profile very similar to that of the beef enzyme, with several recognizable main components in the high-M_r range (>25,000). The human complex I profile diverged from the beef enzyme profile in the low-M_r region, in agreement with previous observations on rat and rabbit complex I (M.W.J.C. and C.I.R., unpublished observations). In immunoblot assays with SDS-denatured human kidney submitochondrial particles, antiserum 1 showed a wide reactivity with human proteins, revealing at least 12 components in the M_r range 10,000–50,000.

The antiserum described above was tested on an SDS mitochondrial lysate from HeLa cells grown for 22 h in the presence of 40 μg ml^{-1} chloramphenicol[27], labelled with ^{35}S-methionine in the presence of 100 μg ml^{-1} cycloheximide and chased in unlabelled medium for 18 h. Only weak bands corresponding to the product of URF4 and to the putative product of URF5 were detected in the autoradiogram of the immunoprecipitate fractionated on a gel, despite the large amount of radioactivity used in this experiment (Fig. 4*a*, lane 3); these bands, however, were specific, because they were absent or much weaker in the control precipitate obtained with normal serum γ-globulins. A more dramatic result was obtained when the same antiserum was tested on a Triton X-100 mitochondrial lysate from the same cells. Six URF products were precipitated in these conditions, that is, the products of URF1, URF2, URF3, URF4, URF4L and URF5, with a minimal degree of contamination by COI, COII and COIII (Fig. 4*b*, lane 6). In the same conditions, antibodies against the COOH-terminal undecapeptide of COII precipitated COI, COII and COIII (Fig. 4*b*, lane 7); these are part of the intact cytochrome *c* oxidase complex

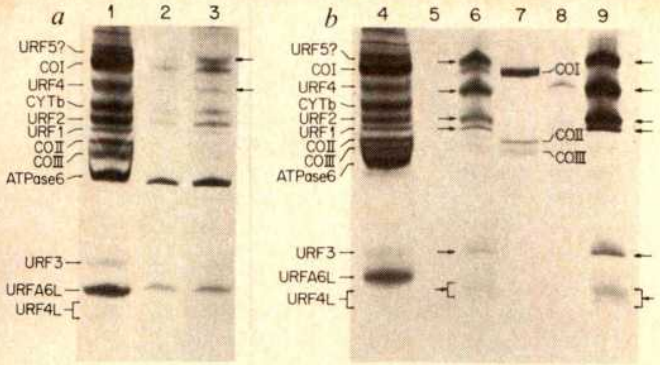

Fig. 4 Antibodies against native bovine complex I immunoprecipitate several URF products. *a*, Immunoprecipitates from an SDS lysate of HeLa cell mitochondria incubated with normal serum γ-globulins (lane 2) or with antiserum 1 against beef heart complex I (lane 3). *b*, Immunoprecipitates from a 0.5% Triton X-100 lysate of HeLa cell mitochondria incubated with normal serum γ-globulins (lane 5), or with antiserum 1 against beef heart complex I (lane 6), or with γ-globulins from an antiserum against the carboxy-terminal undecapeptide of COII (COII-C, ref. 12; lane 7). Lanes 8 and 9 show immunoprecipitates from a 0.2% DOC mitochondrial lysate incubated with normal serum γ-globulins or with antiserum 1 against beef heart complex I, respectively. Lanes 1 and 4, pattern of mitochondrial translation products.

Methods. *a*, Samples of a mitochondrial suspension (10^6 c.p.m., 550 μg protein) from HeLa cells labelled as described in Fig. 2 legend and chased for 2 h were solubilized with SDS and exposed to 50 μl of antiserum 1 against native beef heart complex I or to 500 μg normal serum γ-globulins, as in the experiment described in Fig. 2*a* legend. *b*, Samples of a mitochondrial suspension (2×10^5 c.p.m., 215 μg protein) from cells labelled and chased as described in Fig. 2 legend were solubilized with 0.5% Triton X-100 and immunoprecipitated with 25 μl antiserum 1 (lane 6), or with 250 μg γ-globulins from anti-COII-C antiserum (lane 7), as described in Fig. 2*b* legend. An identical sample (lane 9) was solubilized in 25 μl solution containing 0.2% DOC instead of 0.5% Triton X-100; after 20 min at 4 °C, KCl was added to 0.15 M; after a further 10 min, 65 μl of Zysorbin suspension in incubation buffer (adjusted to 0.15 M KCl) were added and the mixture incubated for 30 min at 4 °C, then spun in the microfuge. The supernatant, after addition of 80 μl of incubation buffer and 25 μl antiserum 1, was incubated for 1 h and then mixed with 125 μl of a 0.5% Triton X-100 mitochondrial lysate (12 mg protein ml^{-1}) from unlabelled cells, then SDS to 0.1% and finally 65 μl Zysorbin. At this stage, the sample contained ~0.015% DOC and ~0.5% Triton X-100. Further treatment of the sample was identical to that of the Triton X-100-solubilized sample. As controls, equivalent portions of the Triton X-100 (lane 5) or DOC-solubilized mitochondrial suspension (lane 8) were incubated with 250 μg γ-globulins from normal rabbit serum. Exposure of the autoradiograms was 10 (*a*) or 12 (*b*) days.

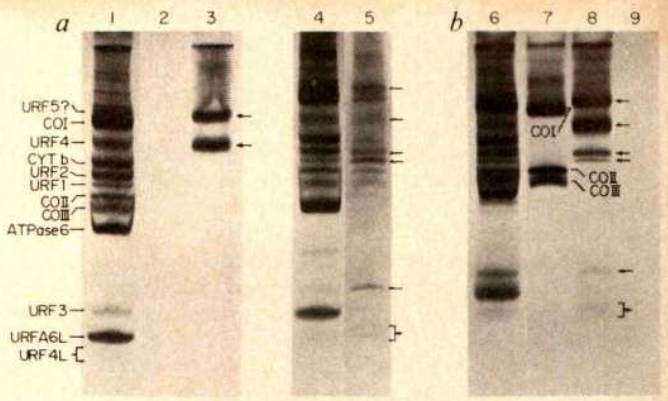

Fig. 5 Effect of detergent treatment (*a*) and labelling conditions (*b*) on the precipitation pattern of URF products by anti-complex I antibodies. *a*, Immunoprecipitates from a 0.5% DOC–1% Triton X-100 mitochondrial lysate incubated with normal serum γ-globulins (lane 2) or with antiserum 1 against beef heart complex I (lane 3). *b*, Immunoprecipitates from a 0.5% Triton X-100 mitochondrial lysate of HeLa cells labelled with ^{35}S-methionine for 2 h, then chased for 2 h (lane 5) or 18 h (lanes 7, 8 and 9), after incubation with antiserum 2 against beef heart complex I (lanes 5 and 8), or with anti-COII-C γ-globulins (lane 7), or with normal serum γ-globulins (lane 9). Lanes 1, 4, 6, pattern of mitochondrial translation products.

Methods. *a*, Two samples of mitochondrial suspension from HeLa cells labelled and chased as described in Fig. 2 legend (3×10^5 c.p.m.; 325 μg protein; lanes 2, 3) were solubilized with 0.5% DOC for 30 min at 4 °C and treated subsequently with 1% Triton X-100 as described previously[25]; after centrifugation at 25,000 r.p.m. in a Spinco 65 rotor for 40 min, the supernatant was incubated with 150 μg normal serum γ-globulin (lane 2) or 15 μl antiserum 1 against beef heart complex I (lane 3). After 2 h incubation at 4 °C and addition of 3 mg unlabelled mitochondrial proteins and SDS to 0.1%, the samples were mixed with 125 μl Zysorbin suspension and further treated as described for the 0.5% Triton X-100-solubilized samples. *b*, Samples of mitochondria from HeLa cells labelled and chased as described in Fig. 2 legend (10^5 c.p.m., 110 μg protein; lane 8), or chased for 2 h after the ^{35}S-methionine pulse instead of 18 h (2×10^5 c.p.m., 190 μg protein; lane 5), were solubilized with 0.5% Triton X-100 and immunoprecipitated with 25 μl (18 h chase) or 50 μl (2 h chase) of antiserum 2 against beef heart complex I, as described in Fig. 2 legend. Equivalent portions of the mitochondrial lysate from 18-h chased cells were incubated with 250 μg γ-globulins from anti-COII-C antiserum (lane 7) or from normal serum (lane 9). Exposure of both autoradiograms in *b* was for 20 days. In a repetition of the immunoprecipitation experiment with 2-h chased material, the normal serum control showed bands of COI, COII and COIII of equal intensity to those of the antiserum-precipitated sample.

(P.M. *et al.*, in preparation). No URF products were observed in the precipitate obtained with normal serum γ-globulins (an independent control experiment showed that complete normal serum gave the same results as normal serum γ-globulins). From the densitometer tracing of the autoradiogram and the methionine content of the various URF products, the labelled products of URF5, URF4, URF2, URF1, URF3 and URF4L in the immunoprecipitate had estimated relative molar concentrations of ~5, 5, 2, 1, 1 and 0.6. In a control experiment, the labelling of all the immunoprecipitated components was sensitive to chloramphenicol.

A more effective precipitation of all six URF products by anti-complex I antibodies was obtained when 0.2% potassium deoxycholate (DOC) in the presence of KCl was used to solubilize the mitochondrial membranes (Fig. 4*b*, lane 9). In these conditions, the relative molar concentrations of the labelled URF products in the immunoprecipitate were similar to those observed in the Triton X-100-solubilized sample (~3, 3, 2, 0.7, 1 and 0.5 for the six polypeptides, respectively). In this last experiment, the solubilized complex I had been exposed to 0.4–0.5% Triton X-100 during the immunoprecipitation and subsequent washing steps (see Fig. 4 legend). Similar results were obtained in another experiment involving exposure of complex I to 0.2% DOC in the absence of Triton X-100 throughout the entire procedure. More drastic conditions of detergent treatment, namely solubilization with 0.5% DOC in the presence of 0.5 M KCl and subsequent treatment with 1% Triton X-100, seem to disrupt the integrity of the complex containing the human URF products. These conditions have been shown previously to leave most of the bovine complex I intact, but to cause a loss of NADH–ubiquinone oxidoreductase activity, although not of NADH–$K_3Fe(CN)_6$ oxidoreductase activity[25]. When the anti-complex I antiserum was tested on mitochondrial membranes treated as outlined above, only the URF4 and URF5 products were detected in the immunoprecipitate (Fig. 5*a*, lane 3); a minimal amount of URF2 and URF1 products was visible in the autoradiogram only after long exposure.

Another factor playing a considerable part in the immunoprecipitation pattern of the URF products are the labelling

conditions. When immunoprecipitation tests were performed on a Triton X-100 mitochondrial lysate from HeLa cells that had been subjected to a short (2 h) chase instead of an 18-h chase, the concentration of URF5 and 4 products precipitated was more than an order of magnitude lower and the amount of URF2 three- to fourfold lower than with material chased for 18 h (compare lanes 5 and 8, Fig. 5). This observation suggests that the incorporation of the newly synthesized URF products into complex I is slow. The experiments of Fig. 5*b* were performed with a different antiserum against bovine complex I (antiserum 2) from that used in the experiments described previously; this antiserum did not precipitate complex I from solubilized human kidney submitochondrial particles, although it reacted with four polypeptides in immunoblot assays. This antiserum, although less effective than antiserum 1, gave a cleaner immunoprecipitate from Triton X-100-solubilized mitochondria than antiserum 1 (compare Fig. 4, lane 6 with Fig. 5, lane 8).

Fraction enriched in six URF products

The results described above strongly suggest that the human respiratory-chain NADH dehydrogenase contains polypeptides encoded in six of the mtDNA URFs. To obtain independent evidence, a mixture of ^{35}S-methionine-labelled HeLa cell mitochondria and human heart mitochondria was subjected to the fractionation scheme which has been used to purify NADH–cytochrome *c* reductase (complex I–III of the respiratory chain) from beef heart mitochondria[28]. The cytochrome *c* oxidase complex from human heart could not be fractionated in the same way as the complex derived from beef heart; as a result, COI, COII and COIII contaminated all fractions to various degrees. Despite this and the constraints imposed on the amount of unlabelled material usable for purification by the requirement for gel analysis and autoradiography, we obtained two fractions (P_5 and P_6, Table 1) enriched in NADH–Q_1 and NADH–$K_3Fe(CN)_6$ oxidoreductase activities. These fractions were essentially free of H^+-ATPase complex, inferred from the almost complete absence of the ATPase 6 and URFA6L polypeptides (Fig. 6). Densitometric measurements showed that ~90% of the ATPase 6 and URFA6L polypeptides remained in the supernatant in the early fractionation step in which complexes I, II and III are precipitated. Fractions P_5 and P_6 were also free of complex II, assayed by succinate dehydrogenase activity. The two fractions were enriched greatly in the six URF products (compare lanes P_5 and P_6 with the marker lane M containing the starting material in Fig. 6). This enrichment could not be correlated with the presence of either cytochrome b–c_1 complex or complex II; the P_6 supernatant, which contained most of the cytochrome *b* polypeptide (estimated ~80% by densitometry) and almost all the succinate dehydrogenase activity of the $P_6 + P_6$ supernatant fractions, showed only a small amount of URF products (estimated to be 10–15%; Fig. 6). Similarly, the enrichment in URF products of P_5 and P_6 could not be attributed to the presence of cytochrome *c* oxidase in these fractions, because both biochemically purified[22] and immunoprecipitated cytochrome *c* oxidase (P.M. *et al.*, in preparation) are totally devoid of URF products. Therefore, it seems that, among the five

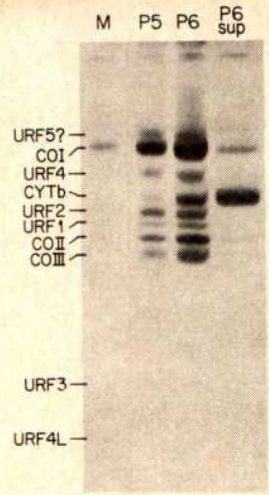

Fig. 6 Distribution of mitochondrial translation products among submitochondrial fractions. P_5, P_6 and P_6 supernatant (P_6 sup) are as defined in Table 1. M, Starting material.
Methods. A mixture of mitochondria from HeLa cells labelled as described in Fig. 2 legend (1.6×10^7 c.p.m., 17 mg protein) and human heart mitochondria (200 mg protein) was subjected to a fractionation scheme for the isolation of NADH–cytochrome *c* reductase (complex I–III)[28]. Equivalent amounts of protein (6.5 μg) of various fractions were run on an SDS/urea polyacrylamide gel.

enzymatic complexes of the oxidative phosphorylation system, the only one whose enrichment can be correlated with the enrichment of P_5 and P_6 in URF products is complex I. From densitometric measurements on the autoradiogram of a gel in which equal amounts of radioactivity of the various samples were analysed, P_5 was estimated to be enriched relative to the starting material ~7-fold in URF4 product and ~5-fold in URF2 and URF1 products; P_6 was enriched ~11-fold in URF4 product and ~7- and 11-fold, respectively, in URF2 and URF1 products. Therefore, the enrichment in URF products in P_5 and P_6 is similar to the enrichment in NADH–Q_1 and NADH–$K_3Fe(CN)_6$ oxidoreductase activities. The deviations from perfect proportionality between NADH dehydrogenase activities and enrichment of URF products in different fractions results from an underestimation of enzyme activities in P_5 and P_6, because of the decrease in solubility of the enzyme that occurs during purification.

Discussion

The conclusion that URF1, URF2, URF3, URF4, URF4L and probably URF5 encode components of the respiratory-chain NADH dehydrogenase is based on four lines of evidence: (1) The products of these URFs are co-precipitated from a Triton X-100 lysate of HeLa cell mitochondria by anti-peptide antibodies specific for individual URF products, especially by anti-URF4L, which suggests that they are components of a complex. (2) Antibodies raised against highly purified bovine complex I react weakly, though specifically, with two URF

Table 1 Enzyme activities of mitochondrial fractions

Fraction	NADH–ferricyanide oxidoreductase (μmol NADH oxidized per min per mg protein)[35]	NADH–Q_1 oxidoreductase (μmol NADH oxidized per min per mg protein)[35]	Succinate dehydrogenase (μmol succinate oxidized per min per mg protein)[36]
Mitochondria	2.7	0.04	0.02
P_5	11.0	0.14	ND
P_6	20.0	0.13	ND
P_6 supernatant	10.0	0.07	0.34

The P_5 fraction is equivalent to complex I–III of Hatefi and Stiggall[28], except that 6.4 ml of 50%-saturated NH_4OAc were added to the previous supernatant per 100 ml of supernatant. The P_6 fraction was obtained from the P_5 supernatant by addition of 6.4 ml of 50%-saturated NH_4OAc per 100 ml of supernatant and pelleting. ND, not detectable at the protein concentration used in the assays.

products in an SDS mitochondrial lysate, that is, with the product of URF4 and the putative product of URF5. (3) The antibodies against bovine complex I precipitate the same six URF products from a DOC or Triton X-100 mitochondrial lysate. (4) A submitochondrial fraction enriched in NADH-Q_1 and NADH-$K_3Fe(CN)_6$ oxidoreductase activities is also enriched in the products of the six URFs.

The URF4-, URF2- and URF3-specific anti-peptide antibodies were less effective than the URF4L-specific antibodies in co-precipitating the other URF products. This may result from a dissociation of the URF product(s) from the complex induced by a destabilizing effect of the antibodies, as has been reported for another mitochondrial complex[29], or to a poor accessibility of the peptide in the complex. The lower capacity of antibodies against native complex I to precipitate URF products from an SDS mitochondrial lysate than from a DOC or Triton X-100 lysate may be because of poor recognition of the SDS-denatured polypeptides by the antibodies, or the effect of SDS on antibody reactivity. Further, it is probable that antibodies against extramitochondrially synthesized components of complex I are also involved in precipitating the complex.

The results described above clearly indicate that the products of URF1, URF2, URF3, URF4, URF4L and the putative product of URF5 are associated closely with complex I. Because this association withstands a variety of detergent treatments, as well as the fractionation procedure for separation of the complexes of the oxidative phosphorylation system, the most plausible interpretation is that the URF products are themselves part of complex I. The enzymatic purity of the complex I preparations used to make the antisera[24] and the evidence indicating that the polypeptides found in complex I preparations are indeed true constituents of the enzyme[25] strongly support this interpretation. It is possible that at least some of the URF products are part of the shell of hydrophobic proteins surrounding the catalytic subunits[20,21]. The estimated M_rs of the URF products discussed here[23], 51,000 (URF5), 39,000-36,000 (URF4), 25,000 (URF2), 24,000 (URF1), 6,000 (URF3) and 3,500 (URF4L), are in reasonable agreement with the reported M_rs for some of the proteins of the insoluble fraction and of the iron-protein fragment of the bovine complex I (ref. 20). We propose that the designations of URF1, URF2, URF3, URF4, URF4L and URF5 be changed to ND (for NADH dehydrogenase) 1, ND2, ND3, ND4, ND4L and ND5, respectively.

In previous work, Hare and Hodges[19] failed to detect any mitochondrially synthesized polypeptide in complex I solubilized from a mixture of unlabelled rat liver mitochondria and labelled rat hepatoma mitochondria and precipitated by antibodies against beef heart complex I. But the labelling conditions used by those authors (2-h exposure of the cells to ^{32}S-methionine without subsequent chase) would allow only very little incorporation of the mitochondrially synthesized, ^{35}S-methionine-labelled subunits into complex I. Further, the authors solubilized complex I from submitochondrial particles with 0.5% DOC and 1% Triton X-100, conditions that we have observed to cause the almost total loss of the four smallest URF products from the HeLa cell immunoprecipitated complex I.

In a more recent investigation[30], the analysis of the mitochondrial translation products and enzyme complexes in a Chinese hamster lung cell mutant, which shows a great decrease in NADH dehydrogenase and cytochrome *c* oxidase activities resulting from an apparently single nuclear mutation, led to the suggestion that complex I contains one or more mtDNA-encoded components[31,32]. The present work provides strong direct evidence for this suggestion.

Functional and evolutionary implications

Yeast mtDNA does not seem to contain any gene homologous to the animal mtDNA URFs that encode components of NADH-ubiquinone oxidoreductase. The NADH dehydrogenase region of the respiratory chain, however, exhibits functional and structural differences in *Saccharomyces* strains compared with the mammalian counterpart; in particular, it lacks site 1 energy coupling[33]. These differences could conceivably result from or be correlated with the absence of some or all of the polypeptides homologous to the animal mtDNA URF products from the yeast complex. On the other hand, it is quite possible that some or all of these polypeptides are encoded in the nucleus and imported from the cytoplasm in yeast. Note that, in contrast to *Saccharomyces* mtDNA, *A. nidulans* mtDNA contains four reading frames that have a convincing amino-acid sequence homology to human URF1, URF3, URF4 and URF5 (ref. 9); a gene homologous to URF1 has been found in *N. crassa* and in *Zea mays*[9]. Genes having a small but significant amino-acid sequence homology to human URF1, URF4 and URF5 and to human URF4 and URF5, respectively, also occur in the kinetoplast maxicircle DNA of *Trypanosoma brucei*[10] and of *Leishmania tarentolae*[11].

It will be of interest to see whether the variation in the complement of mtDNA-encoded subunits in the respiratory-chain NADH dehydrogenase of different organisms is correlated with functional differences. The finding of a variability in genetic control of NADH-ubiquinone oxidoreductase in different organisms extends similar observations concerning the genetic determination of the H^+-ATPase complex[34] and has interesting implications for the evolution of the mitochondrial genome. The evolutionary processes that have led to the segregation of mitochondrial and nuclear genes involved in mitochondriogenesis apparently have followed different paths and progressed to a different extent in different organisms, producing the variety of patterns observed today.

These investigations were supported by NIH grants GM-11726 to G.A. and AM 08126 to Y.H., NSF grant PCM-8118172 to R.F.D. and a grant from the SERC to C.I.R. We thank Dr Claus-Jens Doersen for the gift of human heart mitochondria and Ms Doris Finch and Ms Arger Drew for technical assistance. Identification and comparison of two sequence elements that confer cell-type specific transcription in yeast

Allan M. Miller, Vivian L. MacKay* & Kim A. Nasmyth

MRC Laboratory of Molecular Biology, Hills Road, Cambridge CB2 2QH, UK
* Zymogenetics Corporation, 2121 North 35th Street, Seattle, Washington 98103, USA

The MATα2 *protein of budding yeast represses a set of genes; if the* MATa1 *protein is also present, a further set of genes is repressed. DNA sequence comparisons reveal a 20-base pair 'operator' sequence that is present in genes repressed by* a1/α2. *A related, but distinct, sequence is found in genes repressed by* α2 *alone.*

CELL type in the yeast *Saccharomyces cerevisiae* is determined by the allele (*MATa* or *MATα*) that occupies the *MAT* locus[1]. Mackay and Manney[2,3] proposed that *MAT* is a regulatory locus controlling the expression of several unlinked genes required for mating or sporulation. A physical comparison of *MATa* and *MATα*[4,5] has revealed that each allele produces two transcripts, (*a1*, *a2*) or (*α1*, *α2*). Strathern *et al.*[6] proposed that the *MATα1* protein is a positive regulator of some of the genes required for *α* mating, whereas *MATα2* is a negative regulator of some of those required for *a* mating. In *a*/*α* diploids, *MATa1* and *MATα2* act together as a negative regulator of genes not required in diploids, including *MATα1* (Fig. 1; see ref. 7 for a recent review).

In several cases this regulation seems to be exerted at the level of transcription; for example, *α2* function is required for the repression of transcription of the *a*-specific gene *STE6* (ref. 8) and is thought to act similarly on other genes involved in producing the *a* mating phenotype, such as *STE2*, *BAR1* and *MFa1* (V.L.M., unpublished results; A. Brake, personal communication). Once an *α* cell has mated with an *a* cell to produce an *a*/*α* diploid, the function of *α2* becomes modified. As well as its function in *α* cells, it now acts in conjunction with the *MATa1* gene product to repress an additional set of genes. Therefore, these genes are repressed only if both *MATa1* and *MATα2* are expressed. Such 'haploid-specific' genes include *MATα1* (refs 4, 9), *HO* (ref. 10) and *STE5* (J. Thorner, personal communication and V.L.M., unpublished results). Thus, the *α2* gene product represses one set of genes in *α* cells but an additional set of genes in *a*/*α* diploids.

Both *MATa1* and *MATα2* show protein sequence homology with the 'homoeo domain'[11], a highly conserved protein sequence found in gene products involved in selecting developmental fates in *Drosophila melanogaster*[12–14]. It has also been located in genes of unknown function in other phyla, including vertebrates[15,16]. In the case of *MATa1*, part of the homoeo domain is strikingly similar to the DNA binding domain of bacterial repressors[17], suggesting that *MATa1* encodes a repressor protein. There is more direct evidence that the *MATα2* gene encodes a DNA binding protein. An *α2*-*β*-galactosidase fusion protein binds specifically to the 5′-flanking DNA of *STE2* and *STE6* (A. Johnson, personal communication).

Here we have identified the DNA sequences recognized by the *α2* and the *a1*/*α2* repression systems, first by finding candidates on the basis of DNA sequence comparisons, and second by demonstrating that the proposed sequences are sufficient to confer the appropriate control on an unrelated promoter. Our proposed *α2* and *a1*/*α2* control sequences are different but related; we discuss the means by which the two sets of targets (*α2* against *a1*/*α2*) are distinguished.

a1/*α2* Control of the *HO* gene

One of the haploid-specific genes repressed by the action of *a1* and *α2* is the *HO* gene[10], which is responsible for initiating mating type switching (ref. 18 and F. Heffron, personal communication). We have therefore investigated the *a1*/*α2* control of this gene.

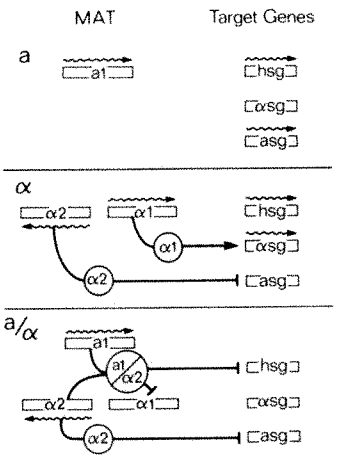

Fig. 1 Mating type control. Left, *MAT* genes: right, unlinked genes which are the targets for their action. Wavy line, gene expression; heavy line, effect of a gene product on the expression of other genes. In an *a* cell, *a*-specific genes (asg) and haploid-specific genes (hsg) are expressed constitutively. In an *α* cell, the asg are repressed by the action of the *α2* gene product, while *α*-specific genes (*α*sg) are activated by the *α1* gene product[6]. When these two cell types mate to produce an *a*/*α* diploid, the *a1* and *α2* gene products together repress the expression of the haploid-specific genes, including *MATα1*.

Two lines of evidence suggest that the sequences that confer *a1*/*α2* repression on *HO* transcription are present in multiple copies distributed widely in the 5′-flanking DNA. The first comes from the deletion analysis by Jensen[19] of plasmids carrying an *HO-lacZ* fusion. A deletion removing all but 296 base pairs (bp) of the DNA flanking the 5′ end of the gene (as measured from the AUG) is fully constitutive, whereas one removing all but 762 bp is fully repressed by the *a*/*α* state. This suggests that *a1*/*α2* control sequences are 5′ to the gene and that they must lie between −296 and −762 from the AUG (Fig. 2). Surprisingly, a deletion (no. 229.102) which removes all the DNA between −172 and −928 is not only transcribed efficiently, but also is fully repressed by the *a*/*α* state when transplaced at the *HO* locus[20]. This suggests that there must be at least two copies of the putative *a1*/*α2* control element, one between −296 and −762, and another either upstream of −928 or in the 3′-flanking sequences.

The distribution of the *a1*/*α2* control elements has also been studied by insertions of the yeast *TRP1* gene at various positions in the *HO* locus. The 850-bp *Eco*RI/*Bgl*II fragment of *TRP1*

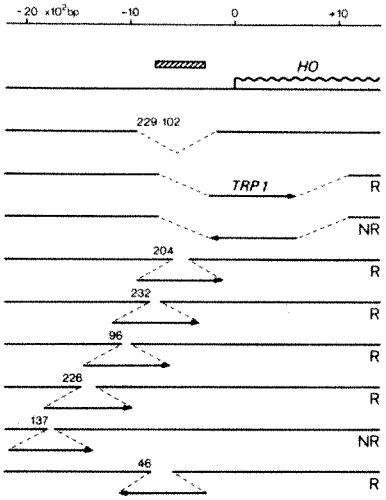

Fig. 2 Redundant a/α control of the *HO* gene. Hatched box, the region defined as important by Jensen[19]; wavy line, ORF of the *HO* gene. The extent of deletion 229.102 is shown. Insertions of the *TRP1* gene into various deletions are also shown; R indicates that in a particular insertion, the *TRP1* gene is repressed in a/α cells; NR indicates that the *TRP1* gene is expressed constitutively. The arrow on the *TRP1* gene indicates the direction of transcription.

Methods. Disruptions of the *HO* gene were constructed and transplaced[20] into the chromosomal *HO* locus of strain K765 (*HMLa MATa HMRa ho::SUP4-o trp1-1 ade2-1 can1-100 his3 leu2-3, 112 ura3*). All insertions fully complemented the *trp1-1* mutation of K765. To test the a/α repression, the transformants were crossed to strain K822 (*HMLa MATα HMRa ho trp1-1 ade2 can1-100 his4 leu2 ura3*) and the TRP$^+$ phenotype of the resulting diploids was scored. In the case of *TRP1* replacing the DNA from −718 to +1,096 (in the same orientation as the *HO* coding sequence), it was shown that the insertion complemented *trp1-1* in a/a and α/α cells, but not in isogeneic a/α cells.

contains all of the coding sequences of the gene encoding (5-P-ribosyl)-anthranilate isomerase but few of its 5′-flanking sequences (only out to −102 from the AUG). Because of its incomplete promoter, the level of expression of this fragment is prone to position effects[21]. Therefore, we have used it as a probe for the regulatory properties of the DNA flanking *HO* by analysing the TRP$^+$ phenotype in *a*, α or a/α *trp*$^-$ cells containing various insertions of *TRP1* in *HO*.

Several *TRP1/HO* insertions (see Fig. 2) have been transferred to the chromosomal *HO* locus using the *SUP4-o* transplacement technique[20]. All the constructions described in Fig. 2 lead to a full TRP$^+$ phenotype in the parent *a* strain. Many of the insertions, however, lose the ability to confer tryptophan prototrophy when an a/α diploid is formed. We have used this specific loss of tryptophan prototrophy as a qualitative measure of the repression of the *TRP1* gene by a/α control. For example, the *TRP1* gene is fully repressed by the a/α state when inserted (in the same orientation as the *HO* coding sequence) as a replacement for the *HO* DNA from −718 to +1,096. In contrast, the gene is constitutive (that is, can confer a TRP$^+$ phenotype to *a*, α and a/α cells) when inserted in the opposite orientation. The simplest interpretation of this result is that *HO* sequences to the left of position −718 can confer a/α repression on the *TRP1* gene and, moreover, they will only do so if joined to its 5′ end. The *TRP1* gene is also regulated when placed (in the same orientation as the *HO* coding sequence) in a number of positions within the interval −300 to −1,450 (see Fig. 2). In contrast, it is not repressed (at least qualitatively) in deletion 137 (−1,737 to −1,777).

These results with *TRP/HO* fusions, taken together with the phenotype of deletion 229.1002 and the results of Jensen[19], suggest that there are several a/α control elements in the interval between −400 and −1,400, and that the 5′ end of the *TRP1* gene must be near one such element to be regulated. Alternatively, there may be fewer elements (although there must be at least two) effective over long distances. Interestingly, an insertion of *TRP1* in the opposite orientation (that is, 5′ end at the 3′ *HO* side) in deletion 46 (−582 to −791) is also under a/α control. This is consistent with the data of Jensen[19] showing that a/α control elements exist in the −296 to −762 interval and suggests that there is one such element to the right of position −582.

In summary, the a/α control of the *HO* gene is redundant, containing two or more control sites within the region −1,777 to −296.

Search for a repeated sequence

In the light of the results described above, the *HO* regulatory region was searched by computer to see whether it contained a repeated sequence motif that satisfied the above criteria. This revealed a sequence motif (T/C)C(A/G)TGTNN(A/T)-NANNTACATCA (Table 1) that is repeated at least 10 times in the 5′-flanking region of the *HO* gene. From the number of occurrences of this motif, its appearance cannot be a chance event; therefore, it must be fulfilling some function. If it is the sequence responsible for $a1/\alpha2$ control, then we would expect to find it it in front of other genes that are repressed by $a1/\alpha2$. Therefore, we have searched the 5′-flanking regions of two genes that are also repressed in the diploid, *MATα1* and *STE5*, for homology with the consensus sequence. At *MATα* there is one occurrence of this sequence (one '$a1/\alpha2$ element'), which lies in the region defined as necessary for $a1/\alpha2$ control[22]. At *STE5* (J. Schultz and J. Thorner, personal communication), there are

Table 1 Examples of the $a1/\alpha2$ element

CONSENSUS:
TC$^{A}_{G}$TGTNN$^{A}_{T}$NANNTACATCA

The sequences of the $a1/\alpha2$ elements that we have found in the *MATα*, *STE5* and *HO* genes are shown. For the elements marked with an asterisk, the orientation of the element has been reversed (taking the complementary strand) to give a closer fit to the consensus sequence. The 'score' shown is a measure of the fit of each element to the consensus sequence[26]; the larger the negative number, the poorer the fit. Thus, the best fit to the consensus sequence is the *HO* −411 element used in the sufficiency experiment (Fig. 3, insert B). An approximate consensus sequence is shown at the foot of the table. Note that this is an imperfect inverted repeat. Sequence information: *MATα* from ref. 34, *STE5* from J. Schultz and J. Thorner (personal communication), and *HO* from M. Squire and M. Smith (personal communication). The 5′-flanking sequence of the *HO* gene (1,950 bp) was compared with itself and with its complementary strand, using DIAGON[35]; this revealed a number of examples of the putative $a1/\alpha2$ element. The *HO* sequence was compared with the *MATα* intergenic region, revealing the same sequence at *MATα1*: these sequences were aligned to produce a frequency matrix (using GETFRQ) and the *HO* sequence was re-analysed using the ANALYSEQ program suite[26]. This revealed a total of 10 examples of this motif in the *HO* gene and two examples in 705 bp of 5′-flanking sequence at *STE5*. A frequency matrix was then constructed including all known instances of the motif; the aligned sequences are shown in the table. The frequency matrix used to search the EMBL library was derived from these examples, except that the *MATα1* sequence was included three times to give it greater weight. We have re-evaluated all the occurrences we have found, testing their score against a frequency matrix that lacks this arbitrary weighting. Thus, all the 'scores' described here refer to a frequency matrix derived from the set of examples shown in the table.

two such *a1/α2* elements in tandem, ~200 bp upstream from the AUG (Table 1).

The computer search of the *HO* gene also revealed another repeated sequence, CACGAAAA. All occurrences of this sequence, however, are contained in the endpoints of the 229.102 deletion, which still retains *a1/α2* control. This CACGAAA motif seems to be involved in the cell-cycle-dependent transcription of the *HO* gene[23].

Control by the repeated sequence

We have asked whether this sequence ((T/C)C(A/G)-TGTNN(A/T)NANNTACATCA) is able to bring an unrelated promoter under cell-type control. To do this we have used the *CYC1* promoter fused to the *Escherichia coli* β-galactosidase gene[24]. The *CYC1* promoter consists of a TATA box and an upstream element required for efficient transcription, the upstream activating site (UAS). This UAS is sensitive to carbon source, being partially repressed when the yeast are grown on glucose-containing media[25]. We have investigated the effect of inserting an *a1/α2* element into the region between the UAS and the TATA box. We took two different examples of the *a1/α2* element from the *HO* gene and inserted them into a *XhoI* site in the *CYC1* promoter, then asked how these inserts affected the activity of the promoter in different cell types. We find that the parent plasmid and the two insert-containing plasmids all direct the production of similar levels of β-galactosidase activity in isogeneic *a*, *α* and *a*$^-$ cells (when tested on indicator plates; data not shown). If we take an *α* cell carrying the plasmid, we can either mate it to an *a* cell or an *a*$^-$ cell to produce two different diploids. One, the *a/α*, is a normal diploid and will repress its haploid-specific genes. The other, the *a*$^-$*/α* cell, will not repress its haploid-specific genes because *MATa1* is absent. When the β-galactosidase activity of these strains is measured, we find that the parent plasmid is not affected by the difference in mating type (Fig. 3). The plasmids containing an *a1/α2* element, however, show a dramatic reduction in the level of β-galactosidase activity in the *a/α* diploid compared with the *a*$^-$*/α* diploid. This implies that a *CYC1* promoter containing an *a1/α2* element is sensitive to *a/α* control.

This result could arise if the insertion of the *a1/α2* element inactivated the *CYC1* promoter and simultaneously generated a novel *a/α*-sensitive promoter to replace it. To demonstrate that the constructions are still being 'driven' by the *CYC1* UAS, we have tested the carbon source dependence of the plasmids. When grown on raffinose (instead of glucose) the parent plasmid and the two insert-containing plasmids all produce a similar, approximately threefold increase in β-galactosidase (Fig. 3). Therefore, the activity of the *CYC1* UAS is blocked in *a/α* diploids by the presence of an *a1/α2* element between the UAS and the TATA box.

Figure 3 also shows that in *α* cells the insert-containing plasmids produce transcripts identical to those produced by the parent plasmid, but in *a/α* cells no transcript is seen. Therefore, the control is operating at the level of transcription. We conclude that our *a1/α2* element is sufficient to confer cell-type-specific expression on a gene.

Search of other genes

Because the *a1/α2* element seems to be sufficient to confer cell-type-specific repression, we would not expect to find good matches to this sequence in genes that are not under *a/α* control. We have searched the European Molecular Biology Laboratory (EMBL) nucleotide sequence library to see whether there are other genes containing this sequence motif, using the ANALYSEQ program[26]. A matrix was constructed containing the frequencies at which each nucleotide T, C, G or A occurs at each position in the *a1/α2* elements. This matrix was then used to scan DNA sequences to find regions showing a good fit to the consensus sequence.

Some caution must be exercised in interpreting the results of such a search, because the 'goodness-of-fit' observed refers to the consensus sequence that we have constructed and does not

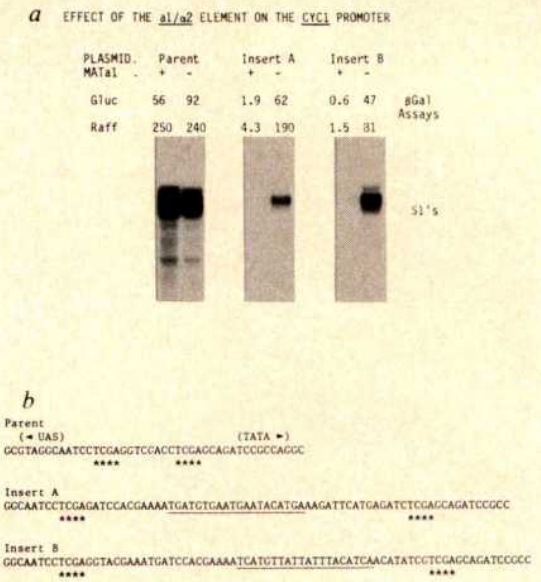

Fig. 3 The *a1/α2* element is sufficient to confer *a/α* control. Two different examples of the *a1/α2* element from the *HO* gene were inserted between the UAS and the TATA box of the *CYC1* promoter driving the β-galactosidase gene. These plasmids were used to transform an *a/α* diploid and the isogeneic *a*$^-$*/α* diploid. *a*, Levels of β-galactosidase (β-Gal) produced in exponentially growing cells are shown, both for raffinose and for glucose as carbon source. Levels of RNA produced by the plasmids were measured by the protection of radiolabelled DNA from S_1 nuclease digestion. *b*, Sequences of the constructions with the *a1/α2* elements underlined. Insert A is *HO* −736; insert B, *HO* −411 (Table 1). Asterisks denote the limits of the inserted fragments.

Methods. DNAs used: Plasmid pHO DNA source was a 4.3-kb *Sau*3A partial fragment and the *Xho* linker mutant 204 derived from it[20]. The *CYC1*-β-galactosidase fusion was pLGΔ312 (a gift of L. Guarente)[36]. The vector for sequencing was M13 mp10 (ref. 37). Cloning of the *a1/α2* elements into the *CYC1* promoter. The *HO* plasmid was digested with *Bam*HI and *Bgl*II, filled in and blunt-end ligated into the filled-in *Xho*I site of pLGΔ-312 (insert A)[36]. *Xho*-linker mutant H204 was digested with *Xho*I and *Nru*I and ligated into the *Xho*I site of pLGΔ312 (insert B). Recombinants were identified by colony hybridization[38] and their identity confirmed by subcloning and sequencing. The *Sma*I/*Bam*HI fragment of pLGΔ-312 carrying the *a1/α2* element insert was cloned into *Hin*cII/*Bam*HI-cut M13mp10. M13 carrying the relevant insert were identified by plaque hybridization and sequenced by the dideoxy-technique. β-Galactosidase assays were performed using the technique of Miller[39]. Cells were collected by centrifugation, resuspended in Z buffer and permeabilized with $CHCl_3$/SDS. After the reaction was stopped with base, cell debris was removed by centrifugation before measuring the A_{420}. Units were measured as $1{,}000 \times A_{420}/A_{660} \times$time (min). RNA samples were taken from cells growing exponentially on glucose and the level of transcription from the plasmid measured as described previously[40]. The copy number of the plasmids did not vary. The DNA probe used is the *Xho*I/*Hin*cII fragment of pLGΔ-312 cloned into *Sal*I/*Sma*I-cut M13mp9 (ref. 37). For the β-galactosidase assays the *MATα* strain used was K822 (Fig. 2); this was mated with either W303-1A (*HMLα MATa HMRa ade2-1 can1-100 his3-11, 15 leu2-3 trp1-1 ura3*) or its derivative RS3 (*HMLα mat*::*LEU2 hmr*::*TRP1 ade2-1 can1-100 his3-11, 15 leu2-3 trp1-1 ura3*). The *mat*::*LEU2* construction is described in ref. 21, and the *hmr*::*TRP1* construction was the kind gift of A. Brand (in preparation). These were transplaced into the yeast chromosome[41]. For the RNA measurements, the strains used were W303-1B (*HMLα MATα HMRa ade2-1 can1-100 his3-11, 15 leu2-3 trp1-1 ura3*) and Y65, which is isogenic, except that it carries a deletion of HMR_E that causes expression of *HMRa1* (A. Brand, manuscript in preparation.)

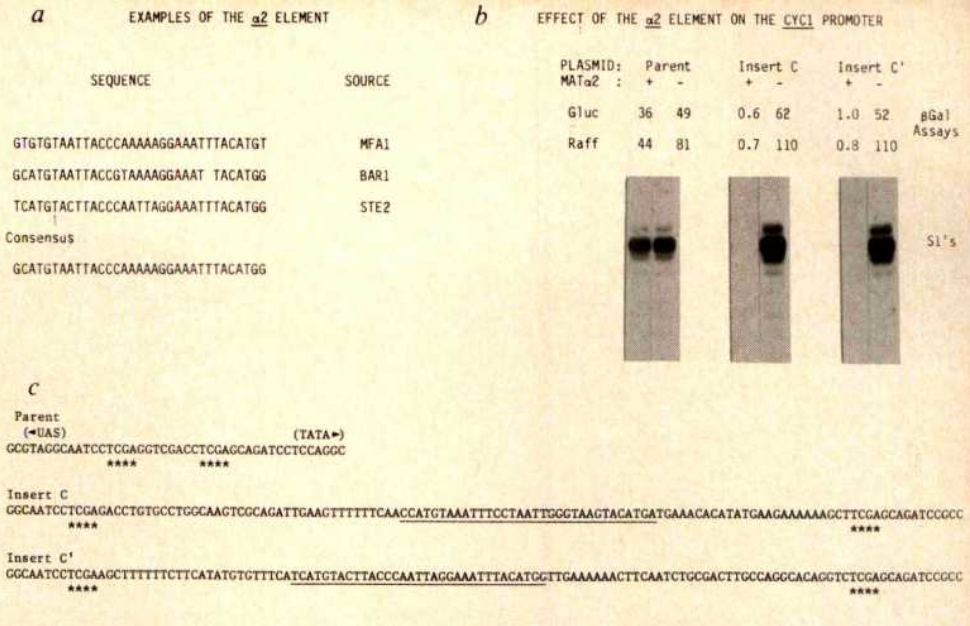

Fig. 4 Sequence of the $\alpha 2$ element and its effect on the *CYC1* promoter. *a*, Sequences of the $\alpha 2$ elements at the *MFa1*, *BAR1* and *STE2* genes. Note that the consensus sequence is an approximate inverted repeat. Sequence information is from A. Brake (personal communication), V.L.M (unpublished results) and this work, respectively. *b*, Effect of the $\alpha 2$ element on the *CYC1* promoter. A 97-bp fragment of the *STE2* gene carrying an $\alpha 2$ element was inserted in both orientations into the *CYC1* promoter. Here we show the levels of β-galactosidase produced by these constructs in isogeneic $a1^-$ and $a1^-\,\alpha 2^-$ cells, both for raffinose and for glucose as carbon source. Levels of RNA produced were measured by the protection of radiolabelled DNA from S_1 nuclease digestion. *c*, Sequences of the constructions with the $\alpha 2$ element underlined. Asterisks denote the limits of the inserted fragments.

Methods. The sequences of the 5′-flanking region of the *BAR1* (690 bp) and *MFa1* (628 bp) genes were compared with each other, and with the 400-bp *Hin*dIII fragment of *STE2* using DIAGON[35]. This revealed the sequences shown here. Sequencing *STE2*:pZV37 (which carries a *STE2*-complementing *Pst*I/*Eco*RI fragment in pUC; V.L.M.) was digested with *Hin*dIII and ligated with *Hin*dIII-cut M13mp10. The sequence was then derived from each end by the dideoxy technique[42]. Inserting a fragment of *STE2* into the *CYC1* promoter. The plasmid carrying the *STE2* gene (pZV37) was digested with *Hin*dIII and *Ava*II and blunt-end ligated into *Xho*I-cut pLGΔ312. Recombinants were identified by colony hybridization and their identity confirmed by subcloning and sequencing. The *Sma*I/*Bam*HI fragment of pLGΔ-312 carrying the $\alpha 2$ element insert was cloned into *Hin*cII/*Bam*HI-cut M13mp10. These recombinants were sequenced. β-Galactosidase assays and RNA measurements were performed as in Fig. 3. The strains used were RS3 (Fig. 3, which is $a1^-\,\alpha 2^-$) and M48 (*HMLα MATα2 matα1::LEU2 hmr::TRP1 ade2-1 can1-100 his3-11, 15 leu2-3 trp1-1 ura3*) (this work). The *MATα2 matα1::LEU2* construction was the gift of L. Breeden (manuscript in preparation).

necessarily reflect exactly what is important for a/α repression *in vivo*.

We have searched 61 kilobases (kb) of yeast DNA sequence in the EMBL nucleotide sequence library and find only one significant match within the 5′-flanking region of any gene. The *MFα1* gene[27] has the sequence CCATGTGAAAAGA-TGCATCT (which would score −15.5 in Table 1) at −230 bp from the AUG. *MFα1* encodes the mating pheromone of the α cell and is an α-specific gene whose transcription is dependent on the *MATα1* gene product[6] (Fig. 1). *MFα1* is not expressed in a/α diploids, partly because *MATα1* is absent. There must, however, be a second a/α-dependent control as *MFα1* is still not expressed in a/α diploids when *MATα1* is expressed constitutively[22]. Our finding that *MFα1* contains a possible $a1/\alpha 2$ control element suggests that this second control is exerted directly by the $a1/\alpha 2$ repressor.

We also find several matches that occur in the open reading frames (ORFs) of genes. We believe that these occurrences of the $a1/\alpha 2$ element do not affect transcription, as transcription is not altered if the $a1/\alpha 2$ element is inserted into the ORF, rather than the promoter, of the *CYC1*-β-galactosidase gene fusion (data not shown). If the matches to the $a1/\alpha 2$ element found in ORFs have no biological effect, then they give a measure of the significance of the matches shown in Table 1. Our search revealed 10 examples of putative $a1/\alpha 2$ elements that would score −16.2 or better in Table 1; therefore, we conclude that such good fits to the consensus sequence should only occur at random once every 6 kb.

$\alpha 2$-Mediated repression

We have shown that the sequence motif (T/C)C(A/G)TGTNN-(A/T)NANNTACATCA is sufficient to confer $a1/\alpha 2$-mediated repression. We know from the biology of yeast mating type that genes carrying this sequence (the haploid-specific genes) are not repressed by $\alpha 2$ alone (Fig. 1); $\alpha 2$-mediated repression must involve a different, perhaps related, DNA sequence. To address this question, we have analysed the DNA sequences of the 5′-flanking regions of three genes that are repressed by $\alpha 2$ alone, looking for sequences specific to these genes which are related to (but different from) the $a1/\alpha 2$ consensus. Using the DIAGON program of R. Staden[35], we have found that *MFa1*, *BAR1* and *STE2* all have a 30-bp sequence in common (Fig. 4*a*). Although in this instance we have only three examples of the sequence, it is clear from the extent of conservation that this sequence has some function. A. Johnson, K. Wilson and I. Herskowitz (personal communication) have also noted this homology.

Two lines of evidence suggest that this 30-bp sequence is involved in $\alpha 2$ control; first, an $\alpha 2$-β-galactosidase fusion protein binds specifically to this DNA sequence (A. Johnson, personal communication). Second, we have shown that a 97-bp fragment containing the putative $\alpha 2$ element from the *STE2* gene can confer $\alpha 2$ control on the *CYC1* promoter. This has been done by inserting the 97-bp fragment between the UAS and the TATA box of the *CYC1* promoter. We then measured the levels of β-galactosidase in isogeneic $a1^-$ and $a1^-\alpha 2^-$ strains; the only genotypic difference between these strains is that the former produces $\alpha 2$ but the latter does not. We find that the plasmid directs β-galactosidase production in the $a1^-\alpha 2^-$ cell, but not in the $a1^-$ cell. Further, the constructions are still under the same carbon source dependence as the parent plasmid, demonstrating that they are being driven by the *CYC1* promoter (Fig. 4*b*). Figure 4*b* also shows that the control is exerted at the level of transcription.

Thus, the 97-bp fragment can bring the *CYC1* promoter under $\alpha 2$ control. Because of the size of this fragment, we cannot be certain whether our consensus sequence alone is reponsible for the regulation, or whether some other sequence on the fragment is involved. We believe that our consensus sequence is responsible because it is the most dramatic homology between the *MFA1*, *BAR1* and *STE2* sequences, and because it has a sequence related to that of the $a1/\alpha 2$ element (see below).

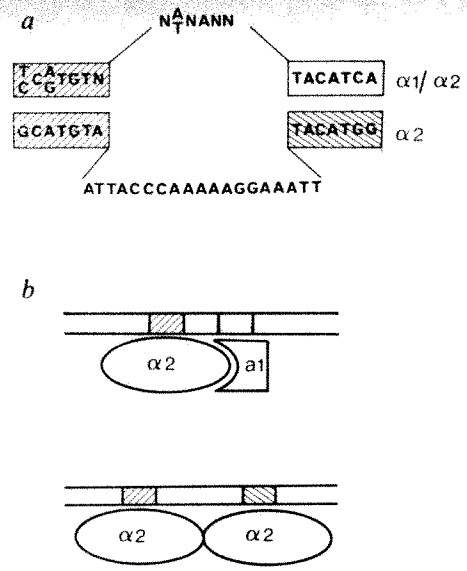

Fig. 5 *a*, Comparison of the *a1/α2* and *α2* elements. The *a1/α2* element (top) is shown aligned with the *α2* element (below) with the common sequence motifs boxed. The TACATG motif is hatched, and the TACATCA motif is stippled. *b*, The combinatorial aspect of mating type control. The *α2* element (bottom) consists of two *α2* half-sites correctly spaced to accommodate the *α2* dimer. The *a1/α2* element (above), in contrast, consists of an *a1* and an *α2* half-site spaced correctly for the 'heterodimer'. It may be that only the spacing of the half-sites is important; alternatively the difference between their sequences may also be important. The critical aspect is that the *α2* half-site in the *a1/α2* element cannot be recognized productively by the *α2* because the other half of the element does not allow cooperative binding by both halves of the *α2* dimer. Hence, the *a1/α2* element is recognized productively only if both *a1* and *α2* are present in the same cell. In such a system, the specificity of an operator depends on three major variables: (1) the presence of short DNA sequences to which particular factors bind specifically; (2) the presence of two or more such sequences in close proximity such that cooperative binding may occur; (3) cooperative binding may be dependent critically on the spacing between the sequences. Only when the correct combination of regulatory proteins is present in a cell is the operator affected.

Discussion

We have identified, by DNA sequence comparisons, two separate sequence motifs that seem to confer two different forms of cell-type-specific repression (*a1/α2* repression in diploids and *α2* repression in *α* cells). To demonstrate that these sequences do confer cell-type-specific repression, rather than some other feature that these genes may have in common, we have excised small fragments containing each of these 'elements' and inserted them into the promoter of an unrelated gene, *CYC1*. In these constructions the *CYC1* promoter comes under the appropriate cell-type control, demonstrating that a promoter can be brought under a particular type of regulation merely by the insertion of the appropriate element into it (Figs 3, 4). Therefore, we believe that the sequence (T/C)C(A/G)TGTNN(A/T)NANN-TACATCA (Table 1) is sufficient to confer *a1/α2*-mediated repression and that the sequence GCATGTAATTACCCAAA-AAGGAAATTTACATGG (or a similar sequence) is sufficient to confer *α2*-mediated repression. This conclusion is consistent with other results (A. Johnson and I. Herskowitz, personal communication) showing that an *α2*-*β*-galactosidase fusion protein binds specifically to the latter sequence *in vitro*.

These two sequences define two 'eukaryotic operator' sequences, in that they are short DNA sequences that repress adjoining genes when present in *cis*. The *a1/α2* element seems to function to full effect only when placed between the UAS (an upstream sequence required for efficient transcription[28]) and the TATA box, but not necessarily next to either promoter element. Hence, it is unlikely to function like a prokaryotic operator, which directly excludes RNA polymerase from binding to the promoter[29]. It could act by blocking the transmission of some signal from the UAS to the TATA box, as suggested by the effect of the *lexA* operator on the *GAL1* promoter[30].

How does the *a1/α2* element differ from the *α2* element such that the former is not recognized by *α2*-mediated repression? The *a1/α2* and *α2* elements have related, but distinct sequences; both are inverted repeats and both carry the same sequence motif (ATGT.... ACAT) in inverted orientation. The first and most marked difference between the two operators is the spacing between the inverted repeats; the common ATGT.... ACAT motif is separated by 11 bp in the *a1/α2* element, but by ~24 bp in the *α2* element. Second, the sequence motifs found in inverted orientation may not be identical (see Fig. 5*a*).

What does the presence of the *a1* gene product in the cell do to extend the action of *α2* to include the *a1/α2* element? Protein sequence data suggest that *a1* is a DNA binding protein; the carboxy-terminal domains of *a1* and *α2* are homologous[11], and we know that the *α2* protein is a sequence-specific DNA binding protein (A. Johnson, personal communication). Furthermore, the homologous region includes the helix-turn-helix motif found in prokaryotic DNA binding proteins[17]. We therefore prefer the model in which *a1/α2* exists on the DNA as a heterodimer, with each protein binding to one half of the *a1/α2* element (to one 'half-site'; Fig. 5*b*).

The model for the specificity of an operator described in Fig. 5*b* involves the combinatorial interaction of regulatory proteins on the DNA; in such a system different proteins that recognize the same DNA sequence (the same half-site) could perform very different functions because of the different protein-protein interactions they can make. Thus, it is significant that the *MATα1* and *MATα2* proteins show homology to the homoeo domain[11], which also seems to conserve the prokaryotic helix-turn-helix motif and is therefore believed to be a DNA binding domain[31]. The genes from *Drosophila* that contain the domain[12-14] have quite distinct functions involved in different aspects of the determination of cell fate. It seems probable that the different functions of these different proteins are encoded by their non-homologous regions. These regions could either specify a second DNA-binding specificity, or, analogously to *a1* and *α2*, they could specify a protein-protein interaction.

We find the idea that homoeo proteins may interact in a combinatorial manner with each other and with other proteins attractive, because (as with *a1* and *α2*) different combinations of these selector genes in different cells would activate different cell-type-specific genes. In this way the combinatorial genetic addresses[32,33] of different cells could be 'read' directly by the promoters of the different cell-type-specific genes.

We thank A. Johnson, K. Wilson and I. Herskowitz, J. Schultz and J. Thorner, P. Siliciano and K. Tatchell, and A. Brake for communicating results before publication. We also thank David Stillman and others for helpful comments on the manuscript, Andrea Brand and Linda Breeden for strains and constructions, and Roger Staden and Mike Squire for technical assistance.

MERLIN[1] (the Multi-Element Radio-Linked Interferometer Network) at Jodrell Bank and the VLA[2] (the Very Large Array) in New Mexico are complementary instruments, representing the latest generation of aperture-synthesis radio telescopes; the VLA comprises 27 antennas, which, in the A-configuration, provide spacings of 0.6–36 km, whereas MERLIN is an array of six antennas with spacings of 6–134 km. Thus, MERLIN provides a factor of four greater resolution than VLA, whereas the shorter spacings of the latter provide essential information on large-scale structure. We present here the first map to be produced by combining data from MERLIN and the VLA. The new map, of the quasar 3C179 (redshift, $z = 0.846$), is a considerable improvement on maps made from the individual arrays and reveals greater detail, particularly in the quasar's jet, which seems to be splitting or disrupting.

3C179 is unusual in that it exhibits superluminal motion in its core[3] yet its extended structure is similar to that of many other classical double or triple sources, whose ejection axes are thought to lie close to the plane of the sky. To study the large-scale structure in detail, 3C179 was observed at wavelength (λ) 18 cm for 24 h using MERLIN, giving a resolution of ~0.25 arc s. The instrument's sensitivity to extended emission on a scale $\geq$3 arc s is limited by the shortest baseline. The VLA was used in the A-configuration to obtain a 20-min extended 'snapshot', giving a reliable representation of structure smaller than ~20 arc s, with a resolution of ~1.2 arc s.

The individual data sets were first calibrated and mapped separately to obtain the maps shown in Fig. 1*a*, *b*, which demonstrate clearly the different capabilities of the two instruments. Because MERLIN maps are produced using closure phases[4] rather than absolute phase, absolute positional information is lost. The MERLIN data were therefore self-calibrated using clean components from the VLA map, effectively shifting the position of the MERLIN map to give the correct phase on MERLIN baselines relative to the VLA. The visibility data from the two instruments were concatenated to give baselines ranging from the minimum VLA spacing of 0.6 to 134 km, the maximum MERLIN spacing. The resultant map is shown in Fig. 1*c*, demonstrating detail not seen in either of the individual maps; this is to be expected because the mapping procedure is a nonlinear process.

The slight discrepancy between the values of peak surface brightness in Fig. 1*b* and *c* is attributable to a small difference between the absolute flux scales of the MERLIN and VLA data. Also, the extended emission in the combined map seems to be

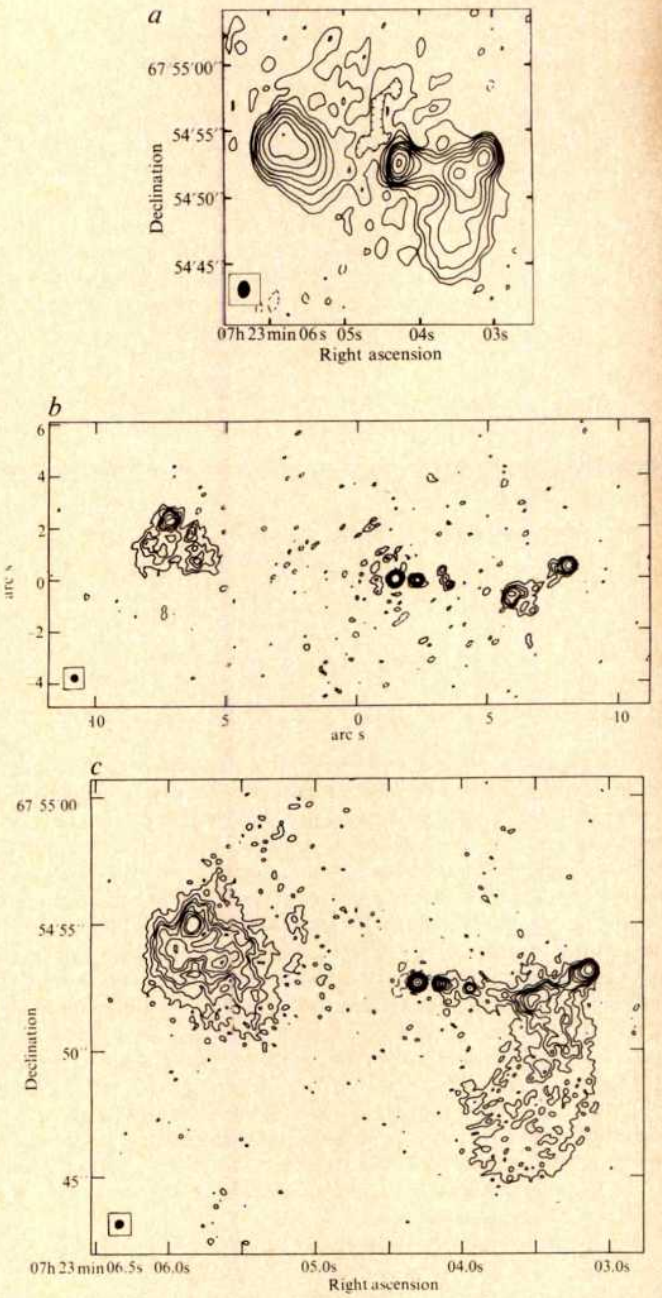

Fig. 1 Maps of 3C179 at λ18 cm. The clean restoring beam in each case is shown in the box in the lower left-hand corner of each map. *a*, VLA map. Contours are plotted at: (−1, 1, 2, 4, 8, 16, 32, 64, 128 and 256) ×0.3% of the peak brightness of 394 mJy per clean beam area. *b*, MERLIN map. Contours are plotted at: (−1, 1, 2, 3, 4, 6, 8, 16, 32, 64) ×0.5% of the peak brightness of 374 mJy per clean beam area. *c*, Combined MERLIN/VLA map. Contours are plotted at: (−1, 1, 2, 3, 4, 6, 8, 12, 16, 32, 64, 128, 256) ×0.3% of the peak brightness of 364 mJy per clean beam area.

weaker than in the VLA map. This is simply a resolution effect; when the combined map is convolved to the resolution of the VLA map, the two give identical results.

Some of the extra detail seen by virtue of the improvement in resolution over that of the λ18-cm VLA map is also apparent in a λ6-cm VLA map of Owen and Puschell[5], which has a resolution of ~0.4 arc s compared with 0.28 arc s for our combined map. The extended structure agrees well with that seen in a λ73-cm MERLIN map[6], which has a resolution of 1 arc s. Thus, we believe that the technique of combining data from the two arrays is reliable.

The new map of 3C179 reveals structural details that are not apparent in the maps from the individual data sets or previous maps. The jet is now clearly seen, and, like many other jets, seems to originate from a bright knot close to the core, which may be a reconfinement shock[7]. The VLBI jet[8] emerges from the nucleus in position angle $(PA) - 88°$; in Fig. 1*c* the arc s jet is seen to bend away from this angle, reaching $PA - 99°$ approximately 3 arc s from the core. A further point of interest is the apparent splitting of the jet into two unequal flows with a possible third towards the north. Ray[9] has suggested that Kelvin–Helmholtz instability modes of the order of $n \geq 3$ will produce a rosette-like cross-section through a jet; if these grow unhindered, they may cause a single jet to split into n jets. Alternatively, the jet may be interacting with local matter at the site of the split, causing deflection and partial disruption. A multi-frequency polarization study is planned to check for depolarization, which may indicate the presence of thermal matter.

The overall structure of the quasar is rather asymmetrical; the relaxed structure of the eastern lobe may indicate that it is either not presently supplied by a jet, or supplied by weak and perhaps poorly collimated ejection from the core. Alternatively, the absence of a counter-jet might be explained by relativistic beaming effects. This would seem unlikely if the ejection axis lies close to the plane of the sky; however, the superluminal motion constrains the ejection axis, at least in the core, to be less than ~29° from the line of sight[6]. In common with other sources exhibiting a one-sided arc s jet, the VLBI jet is on the same side of the nucleus, implying a common cause for the asymmetries of the lobes and jets.

Our map illustrates the value of combining MERLIN and VLA data; the VLA resolution can be improved by a factor of four without the need to use a higher frequency, where steep-spectrum emission will be weaker. By using VLA λ6-cm maps and combined MERLIN/VLA maps at λ18 cm, it may be possible to determine spectral indices and depolarization for source components with greater spatial resolution than hitherto.

We thank Ian Browne, Chris Flatters, Tom Muxlow, Larry Rudnick, Dennis Walsh and Peter Wilkinson for helpful advice and comments. D.L.S. thanks the SERC for a studentship and travel funds. The US National Radio Astronomy Observatory (VLA) is operated by Associated Universities Inc., under contract with the NSF.

Periodic minimal surfaces

Alan L. Mackay

Department of Crystallography, Birkbeck College, Malet Street, London WC1E 7HX, UK

A minimal surface is one for which, like a soap film with the same pressure on each side, the mean curvature is zero and, thus, is one where the two principal curvatures are equal and opposite at every point. For every closed circuit in the surface, the area is a minimum. Schwarz[1] and Neovius[2] showed that elements of such surfaces could be put together to give surfaces periodic in three dimensions. These periodic minimal surfaces are geometrical invariants, as are the regular polyhedra, but the former are curved. Minimal surfaces are appropriate for the description of various structures where internal surfaces are prominent and seek to adopt a minimum area or a zero mean curvature subject to their topology; thus they merit more complete numerical characterization. There seem to be at least 18 such surfaces[3], with various symmetries and topologies, related to the crystallographic space groups. Recently, glyceryl mono-oleate (GMO) was shown by Longley and McIntosh[4] to take the shape of the F-surface. The structure postulated is shown here to be in good agreement with an analysis of the fundamental geometry of periodic minimal surfaces.

The F-surface (Schwarz's designation) discussed below would separate the disjunct tetrahedral networks in the cuprite structure (space group Pn3m). The P-surface would separate the two primitive lattices on which the Cs^+ and Cl^- ions in CsCl (space group Pm3m) lie and would be similar to the silicate carcass in rho-zeolite. This P-surface would also closely resemble the surface of zero electrostatic potential in the CsCl structure. The G-surface would separate the two networks postulated by Luzzati and Spegt[5] for strontium myristate (space group Ia3d) and structural correspondence for others of the surfaces can be found.

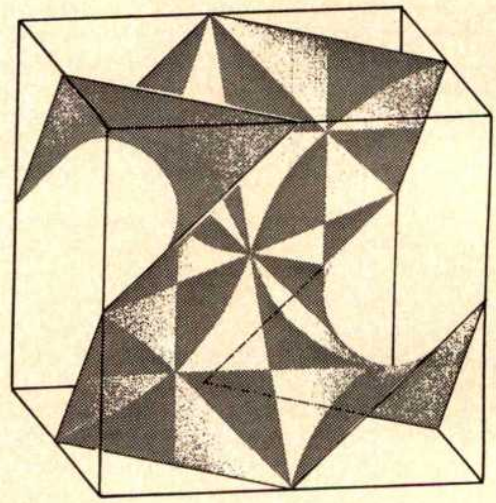

Fig. 1 The cubic unit cell of the F-surface with zero mean curvature[1]. The asymmetric units (48 per cell) are shaded. The space group is Pn3m. In the cuprite Cu_2O structure, or in the double diamond structure of ice VII, this surface would separate the two non-connected networks. In the GMO structure of Longley and McIntosh[4] the surface would be a lipid bilayer with water in the remaining space.

Several of the 18 periodic minimal surfaces described by Schoen[3] (five of which were known to Schwarz) occur as structural elements. Because of their occurrence in lyotropic colloids[4,6], silicates[7–9] and larger-scale biological mineralization[10,11], I have calculated the profiles of several of these surfaces as fundamental structural features.

If the equation for the surface is expressed (in the Monge form) as $z = f(x, y)$, the two-parameter form, then the condition

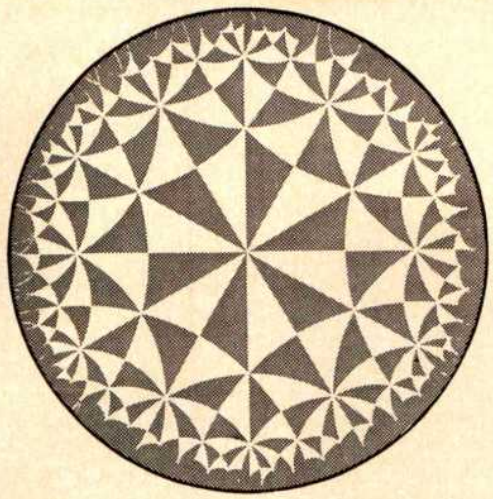

Fig. 2 A stereographic projection of the packing of the same equal triangles as in Fig. 1, but here in the hyperbolic plane, which is a space of constant negative gaussian curvature[13]. The gaussian curvature of the F-surface (Fig. 1) is not constant, but is everywhere negative (except at the umbilical points on the three-fold axes where it is zero). A surface of negative gaussian curvature cannot be mapped onto a plane without tearing or folding, but it can be represented in this way.

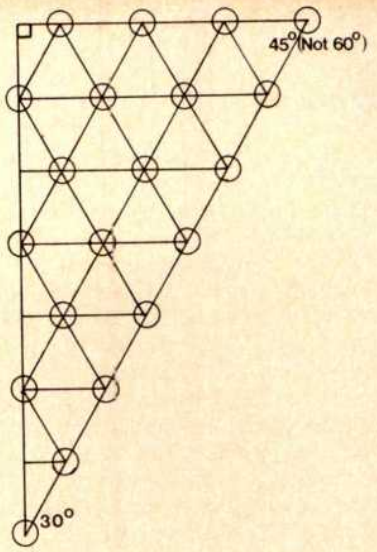

Fig. 3 A possible packing for 12 5/24 molecules of GMO on one side of one of the asymmetric units of the F-surface (Fig. 1). This is an elaboration of the Longley–McIntosh structure and is based on a calculation of the area of the surface. Each molecule would have six neighbours, except that at the 45° vertex (top right), lying on the saddle point where eight triangles meet, which would have eight neighbours. The bilayer (which if planar would be hexagonally close-packed) can be tailored to the F-surface if a disclination occurs where a ring of eight instead of six molecules forms around the saddle point at which the maximum negative gaussian curvature is located.

for zero mean curvature H, is $H = -\text{div}\, n = 0$ (ref. 12), which can be expanded to

$$H = \frac{(1+f_y f_y)f_{xx} - 2f_x f_y f_{xy} + (1+f_x f_x)f_{yy}}{2(1+f_x f_x + f_y f_y)^{3/2}} \qquad (1)$$

where, for example, f_x represents the first partial differential of z with respect to x. This is the Laplace–Young equation.

The gaussian curvature K, the product of the principal curvatures, is given at each point by $K = (f_{xx}f_{yy} - f_{xy}^2)/(1+f_x^2+f_x^2)^2$. The corresponding expression for the area of the element $dx\,dy$ is $dA = (1+f_x f_x + f_y f_y)^{1/2}\,dx\,dy$. An iterative method has been used, calculating the first and second derivatives of eight points nearest on a grid to the given point and adjusting the z-coordinate of the latter to make $H = 0$. K at each point has also been calculated and, as a check, the integrated gaussian curvature, which gives, from $\int K\,dS$, the spherical deficit of the asymmetric unit of area that is bounded by three geodesics. This quantity is also available from the three angles between the geodesics and permits the calculation of the dislocations or disclinations necessary to allow the mapping of a plane net on to the curved surface.

This calculation of z has been performed for the surfaces P, F, CLP, C(P) (Neovius surface) (in Schoen's notation). The calculated areas agree with those found using an analytical method by Schoen (who found 2.3451 for the P-surface and 3.51048 for the C(P) (Neovius surface)), except for the F-surface, where I find 1.9193 whereas Schoen has 2.4177 for the area of surface per unit cube. It is possible that there is here some difference in definition. If the asymmetric unit is taken as a triangle of sides 1/2, $\sqrt{3}/2$, $\sqrt{2}/2$, then the area per unit cube is $3\sqrt{2}/2 = 2.1213$ and the area of these flat panels can clearly be reduced by curving them. If a hyperbolic paraboloid is fitted into a regular tetrahedron, then an area of 1.9212, only slightly greater than our value, is obtained. Schwarz's original diagram of the F-surface (called D by Schoen) is reproduced in modified form in Fig. 1. It can be visualized as the surface separating the two interpenetrating tetrahedral lattices (each of them the diamond network) in the cuprous oxide structure.

From the gaussian curvature we can calculate the mean coordination number (CN) of molecules packed on the curved surface element. The mean CN for a plane surface must be six, but, if the surface is curved synclastically, this can be reduced. For example, if the spherical excess of an equilateral triangle with angles of 72° is 36°, then five of these triangles may meet at a point and we obtain a closed surface of icosahedral symmetry. Similarly, if the surface had a negative curvature so that the spherical deficit of a triangle were 25.71°, then seven triangles, with angles 360/7 = 51.43°, could meet at a point thus tiling an imaginary sphere (a sphere of radius i) of anticlastic curvature.

The spherical deficit for the triangle (with angles 90°, 45° and 30°), which is the unit of pattern for the F-surface, is 15°. The maximum gaussian curvature occurs at the saddle point and gives radii of curvature there of +0.29 and −0.29 (for a unit cube). Figure 2[13] shows a stereographical projection of a packing of these triangles with the same local connectivity as in the F-surface, but in the hyperbolic plane with a constant gaussian curvature. Bonnet's theorem, "that with every surface of constant mean curvature $(2A)^{-1}$ there is a parallel surface of constant gaussian curvature at a distance A from it", is relevant here, but the two surfaces are infinitely far apart (because the minimal surface has a zero mean curvature). The F-surface maps onto the hyperbolic plane in multiple layers joined at the umbilical points.

The best example of a molecular structure taking the form of the F-surface is that of GMO with water, studied by Longley and McIntosh[4]. Their structure is cubic, of space group Pn3m, with $a = 105$ Å. An F-surface of this dimension would have an area of 21,160 $Å^2$ per unit cell. Assuming, as these authors suggest, a 60% GMO content by weight, there should be (with a relative molecular mass 372.55 and a density for neat GMO of 1.028) some 1,140 molecules of GMO per cell. If they form a bilayer, as seems probable, then the area per molecule should be 37 $Å^2$, which agrees with the value of 37.9 ± 0.2 $Å^2$ found by White[14] for planar bilayers of GMO in the liquid-crystalline state.

There are 48 unit triangles (repeated by reflection to give eight to each saddle contained in a $1/2 \times 1/2 \times 1/2$ tetrahedron) of surface per unit cell (each with a spherical deficit of 15°) (Fig. 1). Each should carry ~11.8 molecules on each face to give a bilayer structure.

A disclination of +60° in a hexagonal network corresponds to one 5-fold instead of a 6-fold node. Thus, 12 such units are necessary to make up the 720° total if a sphere is to be covered. A disclination of −60° corresponds to the introduction of an extra segment giving a 7-fold node and a total disclination of 120° would correspond to one 8-fold node or two 7-fold nodes. In the F-surface structure, with a deficit of 15° per asymmetric unit, there is a total disclination strength of 120° for the eight units associated with each saddle point, which is where the maximum curvature is located. Thus, in the Longley-McIntosh GMO structure there should be about one dislocation, in a quasi-planar arrangement otherwise hexagonally close-packed, with an 8-fold instead of a 6-fold node associated with each of the six saddle points per unit cell. Because there are about 11.8 molecules in the asymmetric unit, this might correspond to the idealized packing shown in Fig. 3, where there would be 12 5/24 molecules per asymmetric unit.

The crystallographic structure factors $F(h, k, l)$ for several of the surfaces have also been calculated, because they should also be useful geometrical invariants. For the F-surface the first 10 values are (normalized to $F(0, 0, 0) = 1.9193$ (the total area per cell) and including no atomic scattering curves: $F(0, 0, 0)$, 1.9193; $F(1, 1, 0)$, 0.4775; $F(1, 1, 1)$, 0.4866; $F(2, 0, 0)$, −0.2564; $F(2, 1, 1)$, 0.2129; $F(2, 2, 0)$, 0.2578; $F(2, 2, 1)$, 0.2789; $F(3, 1, 0)$, −0.1877; $F(3, 1, 1)$, −0.0946; $F(2, 2, 2)$, 0.2960; $F(3, 2, 1)$, 0.0952; $F(4, 0, 0)$, 0.1458.

We would expect to encounter the physical occurrence of other of the periodic minimal surfaces, particularly in liquid-crystal systems, although the F-surface discussed here has probably the smallest maximum curvature. We consider it a useful objective to calculate the profiles, curvatures and structure factors of all these periodic minimal surfaces, because they are geometrical invariants to which a number of physical structures can often be usefully referred.

I thank S. Andersson and S. T. Hyde for useful discussions and for a preprint of their paper (ref. 9). I also thank R. H. Mackay for computing facilities and Wiley, New York, for permission to reproduce in modified form the figure cited in ref. 13.

Residence-time distributions in regions of steady-flow systems

B. A. Buffham

Department of Chemical Engineering, Loughborough University of Technology, Loughborough, Leicestershire LE11 3TU, UK

Questions often arise in the applied sciences concerning the transport of material through a system[1-4] (for example, a chemical plant, the cardiovascular system or a river basin). Conserved particles such as molecules, blood corpuscles or colloidal particles passing through the system spend different times in the system even when the flow is steady. The theory of residence times[1,2] may be used to relate tracer studies to theoretical or empirical models. Existing theory mainly concerns complete systems, but a few results have been established[2,5-7] concerning the times that particles spend in a specific region (for example, a particular phase in a chemical reactor, an organ or a backwater) while passing through the system. I show here that the distribution of these 'region residence times' may be calculated from a system model by using a formalism in which the volumes of all the other regions are reduced to zero, allowing the region distribution to be calculated by well-established methods[1,2] that apply to systems.

Most existing theory is confined to systems with closed inlets and outlets. A closed inlet or outlet is one where the particles move solely by bulk flow: once particles enter the system they cannot re-emerge, even temporarily, at the inlet, nor, once they have left the outlet, can they re-enter the system. This restriction is needed to avoid ambiguity when a tally is taken of the particles. The residence-time density function $f(t)$ is defined by saying that $f(t)\mathrm{d}t$ is the proportion of particles entering (or leaving) the system that will spend (or has spent) a length of time between t and $t+\mathrm{d}t$ within the system when it is in the steady state.

To see the importance of the distribution of times that particles spend in a region of a system, consider, for example, the times

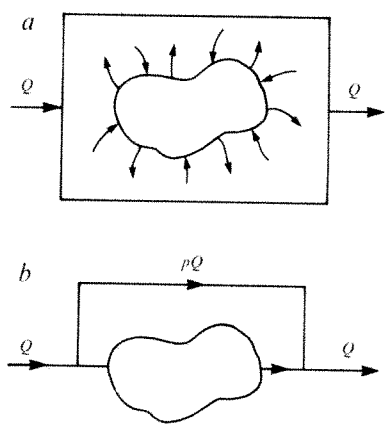

Fig. 1 *a*, A system with a well-mixed region; *b*, the system obtained by using the formalism gives the region residence-time distribution.

that molecules of a drug administered orally spend in a particular organ before being eliminated from the body, or the times that pollutant molecules discharged into a lake spend in a certain zone of the lake before eventually being carried downstream. In these examples there is no need for the region to be closed. A particle may enter a region several times during its journey through the system, or it may bypass the region altogether. Even if the region does have closed boundaries it may be possible for particles to recycle from the region outlet to the region inlet. The residence time in a region is the total time a particle spends in the region between first entering the system and finally leaving it. The residence-time density function (loosely 'distribution') $f_R(t)$ for a region is defined in the same way as the system distribution $f(t)$. Gibilaro[5] has shown that the residence-time distribution for a well-mixed region of a system (Fig. 1*a*) is the sum of an exponential distribution and a spike with zero residence time that represents particles which do not enter the region during their passage through the system. Nauman[6] has shown that the residence-time distribution for an open segment of a

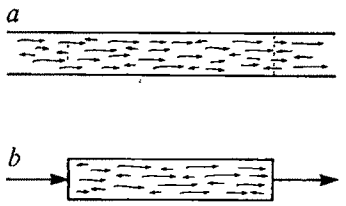

Fig. 2 Axially dispersed piston flow: *a*, showing a segment with open boundaries; *b*, showing the upstream and downstream volumes reduced to zero to find the system that gives the region residence-time distribution.

duct carrying an axially dispersed fluid (Fig. 2*a*) is exactly the same as it would be if the segment were closed. The mean residence time in a region is the ratio of the hold-up in the region to the rate of transmission through the system[7].

Nauman's result was the solution to what had been a perplexing problem. His method was to imagine a particle undergoing a random walk and a clock that stops whenever the particle leaves the segment on which attention is focused and restarts when it re-enters. Residence time is the time the clock records between initial entry and final departure. This provides the clue to deducing the residence-time distribution for an open region. Instead of timing particles with clocks, imagine that each particle is provided with a watch which runs only when the particle is within the region. When a particle leaves the region for the last time, its watch shows the residence time. If, when outside the region, the particles could be induced to travel at infinite speed but along their proper paths, their watches could run continuously. Thus we arrive at the following formalism for deducing the region residence-time distribution from a system model. Reduce the volumes of all regions of the model other than the one of interest to zero and find the residence-time distribution of the resulting model. We can thus establish Gibilaro's and Nauman's results in an extremely simple and straightforward way.

As the portion of the system in Fig. 1*a* outside the well-mixed region is shrunk, particles entering the system reach the well-mixed zone more quickly, return to it more quickly, and so on. At the limit, returning particles return instantaneously. Removing particles from a well-mixed region and instantaneously returning them, to whatever location, has no observable physical effect. Consequently the region residence-time distribution is the same as the system distribution for the system in Fig. 1*b* and is

$$f_R(t) = p\delta(0) + [(1-p)^2 Q/h_R] \exp[-(1-p)Qt/h_R] \quad (1)$$

as Gibilaro[5] showed. The impulse, $p\delta(0)$, represents particles that bypass the region and h_R is the steady-state hold-up of particles there. For models of modest complexity it is usually possible to deduce the bypass fraction p by *ad hoc* methods, but a general procedure is available[8] for network models. For the case of axially dispersed piston flow (Fig. 2*a*), replacing the parts of the system upstream and downstream of the region of interest by regions with no volume gives the closed system of Fig. 2*b* and confirms Nauman's finding[6] that the residence-time distribution for the open region in Fig. 2*a* is the same as it would be if the region were closed.

The formalism can also be used to derive new results. For example, consider a region with a single closed inlet and a single closed outlet embedded within a system (Fig. 3*a*). When the system is shrunk it becomes equivalent to that shown in Fig. 3*b*: it may be possible for particles to bypass the region; other particles either leave after one passage through the region or are recycled. The region residence-time density is

$$f_R(t) = p\delta(0) + (1-p)f_{RS}(t) \quad (2)$$

where $f_{RS}(t)$ is the residence-time density for the recycle system within the broken line in Fig. 3*b*. This density is related to the density of (once-through) sojourn times in the region[2,9].

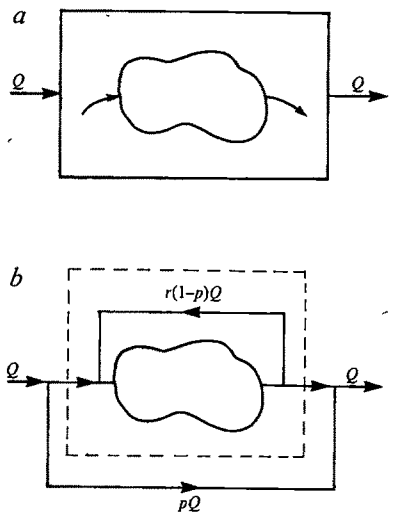

Fig. 3 *a*, A region with a closed inlet and a closed outlet embedded within a system; *b*, the system that gives the region residence-time distribution.

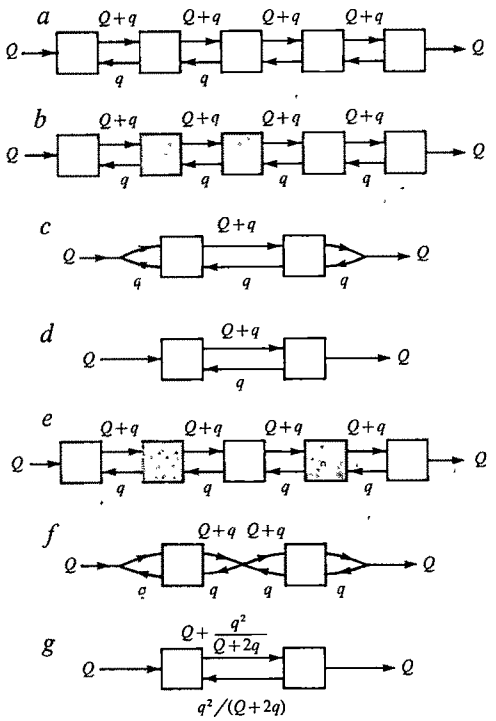

Fig. 4 Sequences of well-mixed zones with backflow: *a*, the basic model; *b*, a region consisting of two adjacent zones; *c*, the system that gives the region residence-time distribution for a region consisting of two adjacent zones according to the formalism; *d*, the system of *c*, further simplified; *e*, a region consisting of two non-adjacent zones; *f*, the system that gives the residence-time distribution for a region consisting of two non-adjacent zones; *g*, the system of *f* further simplified.

Gibilaro[9] has provided a survey of recycle models. The bypass ratio p and recycle ratio r will be reasonably easy to establish for relatively simple models and again the general method[8] can be used for networks.

As a further example, consider the sequence of perfectly-mixed equal-volume zones with backflow shown in Fig. 4*a*. Suppose we wish to know the distribution of residence times in a region that consists of two adjacent zones (Fig. 4*b*). By applying the formalism, the system in Fig. 4*c* is found to have the desired residence-time distribution. This can be simplified

further to give the system in Fig. 4*d*. Application of standard methods[2] shows that the residence-time density is

$$f(t) = (Q/V_R)\sqrt{1+Q/q}\,\{e^{-\lambda_1 Qt/V_R} - e^{-\lambda_2 Qt/V_R}\} \qquad (3)$$

where $\lambda_{1,2} = 2\sqrt{1+Q/q}/(\sqrt{1+Q/q} \pm 1)$ and V_R is the region volume. Backflow cell models have been discussed by others[10-12]: residence-time distributions for regions consisting of several adjacent zones can be deduced from published results[10,11] by using the formalism. We can also find the residence-time distribution for a region consisting of two non-adjacent zones (Fig. 4*e*). When the formalism is invoked, the zone(s) between the two zones comprising the region shrinks into a node (Fig. 4*f*). Of the flow from the left-hand zone to the node, a fraction $(Q+q)/(Q+2q)$ passes on to the right-hand zone and a fraction $q/(Q+2q)$ returns to the left-hand zone. As the latter is returning at once to a well-mixed zone it has just left, it can be disregarded. Thus, the significant left-to-right flow is $(Q+q)^2/(Q+2q)$, which can also be written as $Q+q^2/(Q+2q)$. As the net flow is Q, the significant right-to-left flow is $q^2/(Q+2q)$ (see Fig. 4*g*). It follows by comparing Fig. 4*d* and *g* that the residence-time distribution is given by equation (3), with q replaced by $q^2/(Q+2q)$.

Atmospheric chlorofluoromethanes in the deep equatorial Atlantic

Waters that leave the surface of the ocean and enter the subsurface circulation contain concentrations of CCl_3F (fluorocarbon-11) and CCl_2F_2 (fluorocarbon-12), which reflects the temporal increases of these industrially produced compounds in the atmosphere. These chlorofluoromethanes (CFMs) are extremely stable in the troposphere and in natural waters, they have no known natural sources, and their histories of release to the atmosphere are fairly well known[1]. The atmospheric distributions of CCl_3F and CCl_2F_2 are not strongly dependent on latitude[2,3], and their surface water concentrations can be expected to come into relatively rapid solubility equilibrium with the atmosphere[4]. Recent advances in analytical techniques[5,6] have made possible the routine use of these CFMs as oceanic tracers on a decadal timescale. The results we report here are from the first detailed surveys of CCl_3F and CCl_2F_2 distributions in the northern and tropical Atlantic Ocean. They show that CFM-bearing waters originating in the region of the Labrador Sea have reached the Equator in a well-defined western-boundary undercurrent located at a depth of about 1.6 km, in the Upper North Atlantic Deep Water. Using a simple dilution model, we calculate that this water has taken about 23 yr to reach the equatorial region, and has been diluted about five-fold by CFM-free waters.

Our measurements were carried out aboard R/V *Knorr* during Leg 7 of the Transient Tracers in the Ocean (TTO) North Atlantic Study (NAS) in September–October 1981, and during the three legs of the TTO Tropical Atlantic Study (TAS) from December 1982 to February 1983. The station numbers and locations of these expedition legs are shown in Fig. 1. Concentrations of CCl_3F and CCl_2F_2 were measured at about 15–30 depths at each station, and in samples of marine air, using shipboard electron-capture gas chromatography. The techniques for measuring CFMs have evolved considerably during the course of this work: the NAS measurements were made using a modified version of the technique used earlier in the North Pacific[5], and the TAS measurements were made by a semi-automated low-blank version of the technique used in the Greenland and Norwegian seas[6]. Seawater samples were collected in Niskin bottles and carefully transferred to 100-cm^3 glass syringes to avoid contact with shipboard air, which was generally contaminated in CFMs. Measured seawater volumes of ~30 cm^3 were injected into a stripping chamber, where the dissolved CFMs were purged by a stream of purified carrier gas and were collected on a low-temperature trap for injection into the gas chromatograph using a Porasil C separating column. Impurities with long elution times were removed using standard pre-column techniques. The peaks were detected by a ^{63}Ni electron-capture detector operating in constant current mode, and amounts were determined by peak height measurement on NAS and by digital integration on TAS. Seawater samples were analysed within a few hours of collection. Measured volumes of clean ambient air (~3 cm^3) drawn from a continuously pumped outdoor sampling line and dried with potassium carbonate on NAS and magnesium perchlorate on TAS were analysed by injection into the same low-temperature sampling system.

The system was calibrated by frequent analyses of compressed air secondary standards in various aliquot sizes. The values we report are given on the Scripps Institution of Oceanography (SIO) 1984 calibration scale, which is based on primary standards with near-atmospheric CCl_3F and CCl_2F_2 concentrations prepared in the laboratory by volumetric dilution. The estimated accuracy of this scale is ~1.5% for CCl_3F and ~0.3% for CCl_2F_2. We have also carried out direct intercomparisons between our standards and those used in the Atmospheric Lifetime Experiment (ALE)[7] which demonstrate agreement within expected combined errors: values reported on the ALE scale are 2.5% higher than the SIO 1984 scale for CCl_3F and 1.9% lower than the SIO 1984 scale for CCl_2F_2.

The precision of the seawater measurements, as estimated from the standard deviation of replicate analyses, is about 4% or 0.02 pmol kg^{-1}, whichever is greater, for both CFMs on NAS, and about 1% or 0.005 pmol kg^{-1}, whichever is greater, for both CFMs on TAS. Systematic sampling and handling errors are estimated to be on the same order.

To assess past surface-water CFM concentrations, we have reconstructed the temporal variations in high-latitude Northern Hemisphere tropospheric CCl_3F and CCl_2F_2 mixing ratios in the same way as we have done for the Greenland and Norwegian seas[6]. For the period since 1976, we have used direct measurements[2,3,8], corrected to the SIO 1984 calibration scale. For 1933–76, we have integrated annual CFM release figures[9], assuming tropospheric residence times of 50 yr for CCl_3F and 90 yr for CCl_2F_2, and have normalized these results to match the direct measurements in 1976. These data show monotonic increases in the tropospheric concentrations of both compounds, with build-up of CCl_3F beginning somewhat later but rising more rapidly, so that there has been a steady increase in the CCl_3F/CCl_2F_2 ratio from zero in 1937 to about 0.57 in 1975. Following the discovery that the CFMs represent a threat to the Earth's ozone layer[10], the percentage rates of increase of both of these compounds have gradually decreased to about 6% per year, and there has been no significant change in the tropospheric CCl_3F/CCl_2F_2 ratio since about 1976.

Each of the four TAS hydrographic sections which cross the western boundary of the tropical Atlantic (Fig. 1) show pro-

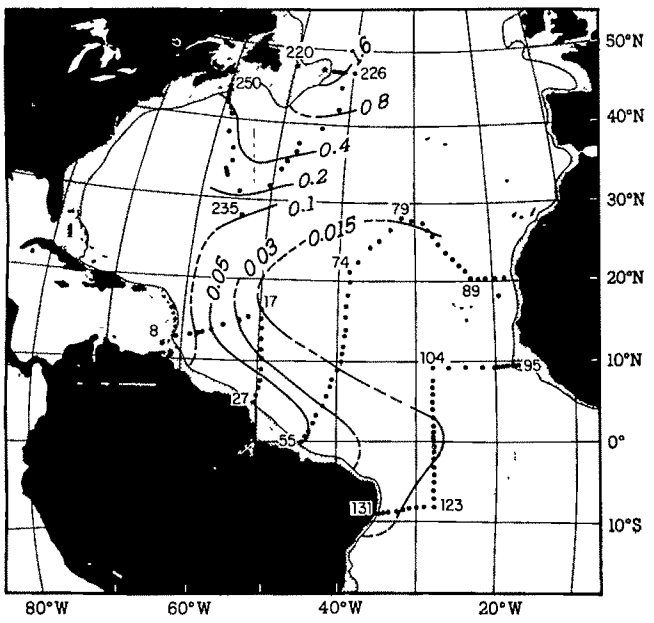

Fig. 1 Station locations and contours of CCl_3F concentrations on the $\sigma_{1.5} = 34.63$ kg m^{-3} isopycnal surface. Stations 220–250 in the northwestern Atlantic are from the NAS expedition and Stations 8–27 and 55–131 in the tropical Atlantic are from the TAS expedition. CCl_3F contours are in units of pmol kg^{-1}, and are spaced at approximately logarithmic intervals in which each successive contour above 0.05 pmol kg^{-1} represents a doubling in concentration.

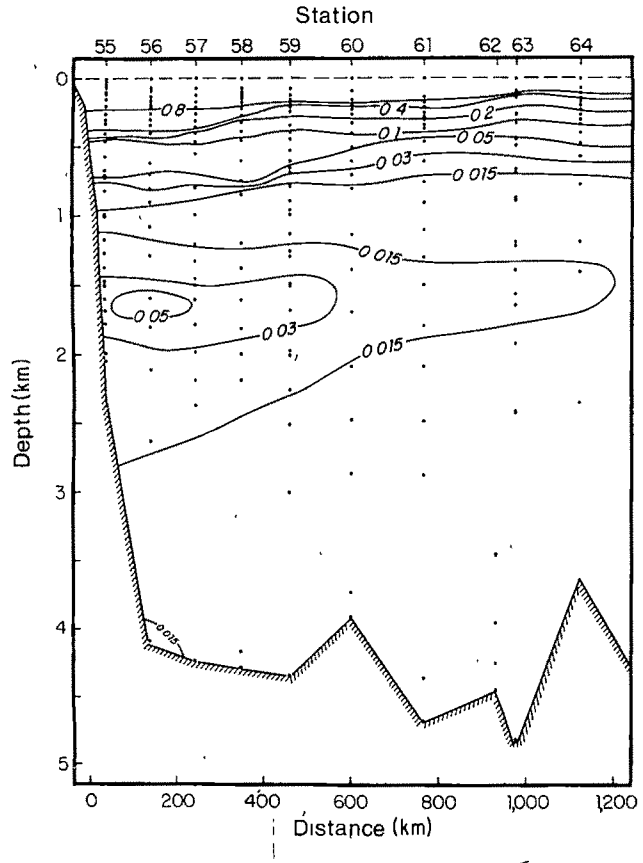

Fig. 2 Concentration of CCl_3F in pmol kg^{-1} on the TAS vertical section extending from Station 55 near the South American continent at the Equator to Station 64 near the Mid-Atlantic Ridge. The contour intervals are as in Fig. 1.

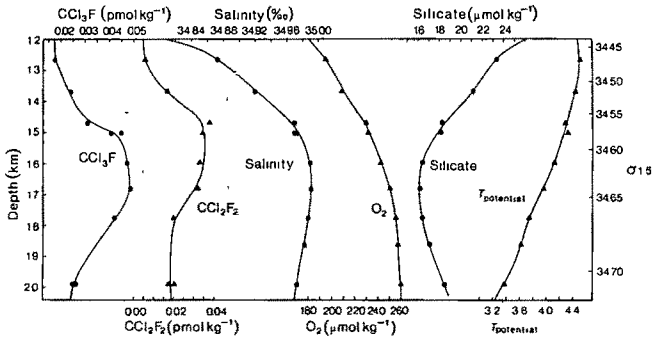

Fig. 3 Vertical profiles of CCl_3F, CCl_2F_2, salinity, oxygen, silicate and potential temperature at TAS Station 55 (0°03′ N, 44°10′ W) versus depth Corresponding values of the potential density anomaly $\sigma_{1.5}$ in kg m^{-3} are labelled along the right ordinate.

nounced maxima in CCl_3F and CCl_2F_2 concentrations at depths of 1.5–1.7 km, with the highest concentrations lying near the South American continent and with detectable maxima extending as much as 1,200 km seaward. The CCl_3F section in Fig. 2, which extends from Station 55 near the continental margin at the Equator to Station 64 near the Mid-Atlantic Ridge, shows an example of this pattern. The CFM concentrations in this mid-depth feature also decrease toward the south, with maximum CCl_3F values ranging from ~0.1 pmol kg^{-1} in the section at 13° N to ~0.015 pmol kg^{-1} in the section at 9° S. The CFM data thus suggest that this feature is produced by a southward-flowing western boundary undercurrent.

The relationship of this feature to the regional hydrography is shown in Fig. 3 by the depth profiles of CCl_3F, CCl_2F_2, salinity, O_2, silicate and potential temperature (the temperature a parcel of water would have if moved adiabatically to the sea surface) at TAS Station 55. The maxima in CCl_3F and CCl_2F_2 coincide with a maximum in salinity and a minimum in silicate which mark the core of the Upper North Atlantic Deep Water (UNADW)[11]. The potential density anomaly $\sigma_{1.5}$ (defined[12] by $\sigma_{1.5} = \rho_{1.5} - 10^3$, where $\rho_{1.5}$ is the density[13] expressed in kg m^{-3} that a parcel of seawater would have if moved adiabatically to the depth where the pressure is 1,500 dbar) of this layer is ~34.63 kg m^{-3}.

Tropical Atlantic waters in the potential density range of the UNADW are influenced by waters originating both in the Mediterranean Sea and in the region of the Labrador Sea. The salinity maximum of the UNADW is of Mediterranean origin, although in the western tropical Atlantic it has been truncated, and thus moved to a greater potential density, by the intrusion from the south of the overlying low-salinity Antarctic Intermediate Water (AAIW). Similarly, the silicate minimum, which is characteristic of waters of both Mediterranean and Labrador Sea origin, is truncated by the intrusion of overlying high-silicate AAIW. We emphasize that the coincidence of the depths of the CFM maxima with the extrema in salinity and silicate results simply from truncation of the profiles by low-CFM AAIW and does not necessarily indicate a common source region for these species in the UNADW.

The truncation of the UNADW extrema by the AAIW illustrates a major difficulty in using the core layer method to trace the waters in the UNADW to their source regions. We have instead evaluated the origin of the high CFMs in the UNADW by isopycnal layer analysis[12] using the $\sigma_{1.5} = 34.63$ kg m^{-3} potential density surface. This surface coincides with the UNADW CFM maxima we observe in the western tropical Atlantic and is characterized in this region by a potential temperature of ~4.0 °C and a salinity of ~34.98‰. Towards the north-east, the potential temperature and salinity on this surface increase in response to the influence of the Mediterranean outflow, reaching values of ~5.1 °C and ~35.20‰ at the northernmost TAS stations in the Canary Basin. Towards the north-west, our NAS data show decreases in potential temperature and salinity on this

isopycnal surface as the proportion of Mediterranean water is reduced. This effect is most pronounced at our northernmost stations near the Grand Banks, where this surface intersects a western boundary current of Labrador Sea Water (LSW) which is marked by decreases in potential temperature and salinity from ~3.6 °C and ~34.92‰ at Station 226 to ~3.3 °C and ~34.86‰ at Station 222. Throughout our study area, the depth of this isopycnal surface lies at ~1.6 km, except near the Grand Banks where it shoals to ~1.0 km.

The potential density and formation rate of LSW during 1948–75 have been evaluated[14] using its potential vorticity minimum as a tracer. Because that study used an earlier equation of state, its values of $\sigma_{1.5}$ must be reduced by 0.03 kg m^{-3} to place them on the same scale as ours. Thus, our $\sigma_{1.5}$ = 34.63 kg m^{-3} isopycnal surface lies near the lower limit of the LSW potential density range, ~0.03 kg m^{-3} less than the most common density of the LSW core. Based on temporal variations in salinity, the $\sigma_{1.5}$ = 34.63 kg m^{-3} surface in the Labrador Sea is believed[14] to have been actively renewed during 1948–63 and to have been relatively isolated from renewal subsequently during 1964–71.

The geographical distribution of CCl_3F concentrations on the $\sigma_{1.5}$ = 34.63 kg m^{-3} isopycnal surface at our TAS and NAS station locations is shown by the contours in Fig. 1. As an approximate compensation for the 1-yr difference in expedition dates, we have increased the values at the NAS stations by 6% to make the contours in this region approximately synoptic with the TAS measurements. In the equatorial region, these distributions do not show increasing CFM concentrations as one moves along the isopycnal surface from the western boundary of the Atlantic towards the high salinity water which extends outward from the Mediterranean. In the western Atlantic, however, CFM concentrations on the isopycnal surface increase steadily towards the Labrador Sea source region in the north. As well as these geographical relationships, we note that increasing CFM concentrations correlate with decreasing salinity everywhere on this isopycnal surface, except in the region of TAS Stations 79–82, where the influence of CFMs from the Mediterranean is clearly reflected by a correlation between increasing CFM concentrations and increasing salinity. We therefore conclude that the CFMs in the UNADW of the tropical western Atlantic must originate in the region of the Labrador Sea.

We have used a simple model to calculate the approximate time required for water to be transported from the surface of the Labrador Sea to the UNADW in the western tropical Atlantic, as well as the degree of dilution which occurs during this process. We have assumed that CCl_3F and CCl_2F_2 concentrations in Labrador Sea surface waters during wintertime convection are in approximate solubility equilibrium with the atmosphere, and that during their southward transport in a western boundary undercurrent they are diluted by mixing with surrounding waters which are essentially CFM-free. In this model, the transport time for the CFM-bearing component is given by the CCl_3F/CCl_2F_2 ratio, and the degree of dilution is given by the concentrations.

In these calculations, we have used the temporal variations in tropospheric CFM mixing ratios discussed above, and solubilities in LSW of 3.5 °C potential temperature and 34.9‰ salinity, expressed in terms of the F solubility function[15], of 0.0213 mol kg^{-1} atm^{-1} for CCl_3F and 0.00533 mol kg^{-1} atm^{-1} for CCl_2F_2 (M.J.W. and R.F.W., unpublished gas chromatographic solubility measurements).

The NAS measurements of LSW near the Grand Banks at ~47 °N and near Nova Scotia at ~42° N show CCl_3F/CCl_2F_2 ratios of 2.25 ± 0.1, which correspond to an equilibrium atmospheric ratio of 0.56 ± 0.02. This ratio is indistinguishable from the atmospheric ratio of 0.56 in 1981 during the NAS expedition, and because of the constancy of the CCl_3F/CCL_2F_2 ratio during the late 1970s, our ratio measurements can only constrain the mean transport time of these waters to <9 yr. Calculated dilution factors for the LSW found in this region are also poorly constrained, by the uncertainty in the transport time and by the range of the measured concentrations, to between zero and three-fold.

The TAS measurements of UNADW in the western boundary undercurrent of the equatorial Atlantic show CCl_3F/CCl_2F_2 ratios ranging from 1.2 to 1.5, with a mean value of ~1.4. Although we expect from the southward decrease in CFM concentrations that there is a corresponding decrease in CCl_3F/CCl_2F_2 ratio between 13° N and 9° S, we are unable to detect a significant trend because of the large error associated with the ratio measurement at these low concentrations. Including analytical errors, the mean atmospheric CCl_3F/CCl_2F_2 ratio in equilibrium with these waters is 0.35 ± 0.11, which corresponds to the atmospheric composition in 1960 ± 5 yr. The degree of dilution which this water has experienced is very strongly dependent on the uncertainty in the calculated transport time because the concentrations of CCl_3F and CCl_2F_2 in the atmosphere increased approximately seven-fold and four-fold respectively, between 1955 and 1965. For surface water equilibrated with the atmosphere in 1960, we calculate that the CCl_3F concentration of 0.05 pmol kg^{-1} found near the South American continent at the Equator has been diluted approximately five-fold by CFM-free water.

Thus, our data show that waters originating in the region of the Labrador Sea have transported atmospheric CFMs into the equatorial Atlantic along a western boundary undercurrent of UNADW, a distance of about 10,000 km, in about 23 yr. This corresponds to a mean velocity of about 1.4 cm s^{-1}. In the equatorial region, the CFM distributions show that this western boundary flow crosses into the Southern Hemisphere to at least 9° S and suggest that the flow also extends eastward along the Equator.

It is important to recognize that the transport times and dilution factors we have calculated are strongly model dependent. Because atmospheric CFM concentrations have tended to rise exponentially rather than linearly, if subsurface mixing occurs between CFM-bearing waters of different ages, the resulting apparent age will be biased in favour of the younger component. Also, the assumption of atmospheric equilibrium in surface waters may be inappropriate in convective processes and under such conditions the CFM ratios may be affected by kinetics. Further research in the Labrador Sea and in other areas of active water-mass formation is essential for quantifying these relationships.

We thank F. A. Van Woy and P. K. Salameh for their contributions to the collection and processing of the data; R. A. Fine, J. L. Reid and L. D. Talley for their discussions on the hydrography of the North Atlantic; R. A. Rasmussen for his collaboration in the standard intercalibrations; and the officers and crew of the R/V *Knorr*, the TTO scientific participants and the staff of the SIO Physical and Chemical Oceanographic Data Facility for their help and cooperation. This research was supported by the Marine Chemistry Program of the NSF.

An understanding of the phenomenon of acid rain requires the identification of the sources of the species affecting the *p*H of rainwater, both natural and anthropogenic, and their temporal and spatial development. The scant data concerning the historical development of the acidity in precipitation are from urban regions or their vicinity, where local effects dominate and obscure the hemispherical pattern[1]. The Greenland ice sheet allows us to trace the evolution of the acid rain in a remote location that is free from local effects. Sulphuric and nitric acids are the two species that dominate the acidity in precipitation[2–4]. We report here measurements of $[SO_4^{2-}]$ and $[NO_3^-]$ in firn samples spanning the period 1895–1978. Samples, each covering 1 yr, were taken from a 70-m core drilled at Dye 3, South Greenland; $[NO_3^-]$ and $[SO_4^{2-}]$ both increased by a factor of ~2 during the period. By comparing the recent concentrations of nitrate and sulphate with those resulting from natural sources, we conclude that anthropogenic emissions of the precursors (NO_x, SO_2) had already surpassed natural sources in the late 1950s.

In 1980 a shallow electromechanically drilled core was collected near Dye 3 (65°11'N, 43°30'W) in the frame of the US–Danish–Swiss Greenland Ice Sheet Program. The main purpose of this core was to provide samples for studying the influence of the 11-yr solar cycle on the ^{10}Be concentration in the firn[5]. As a supplementary study, anion concentrations were determined by ion chromatography as possible correction factors to eliminate 'meteorological noise' in the ^{10}Be data. To avoid contamination, the drill site was located 2 km north of the radar station and perpendicular to the main wind direction. In the field, the acidity was qualitatively determined by solid electrical conductivity measurement (ECM)[6] and a small strip of the core was cut for continuous $\delta^{18}O$ analysis with a resolution of eight samples per calculated year. After field sampling, the cores were packed in polyethylene tubes and sent back to the laboratory. The volcanic Katmai eruption, which took place in 1912 in Alaska, is clearly visible in the ECM record and served as an internal check on the accuracy of the timescale used. The $\delta^{18}O$ and ECM results showed the mean snow accumulation rate at Dye 3 to be 50-cm water equivalent yr^{-1} and provided an age/depth relation which allowed us to cut the core into annual samples. To remove external contamination before chemical analysis, the outer layer of the firn was removed with a stainless steel microtome knife. All sample treatment was done in a cold room (−20 °C). The samples were melted in a covered polyethylene beaker and aliquots were taken for chemical analysis. To check whether the sampling and melting procedure introduces any noticeable background, we treated ultra-pure water in the same manner as the samples. This water was frozen in the polyethylene beaker in the cold room and re-melted in the laboratory. Blank values were below 8 parts per 10^9 (p.p.b.) (ng per g ice) for the measured species; the reproducibility of the measurements was better than 5%. Figures 1 and 2 show $[NO_3^-]$ and $[SO_4^{2-}]$ during the period 1895–1978. To reveal the general trend, a spline-smoothed curve has been drawn through the points. Nitrate and sulphate show an increasing trend with a large year-to-year fluctuation; our measured concentrations can be compared with published data[7–9]. For the years 1895–1904 we measured a mean sulphate level of 36 p.p.b., which is higher than for the two time periods 1539–1577 and 1773–1791, where the sulphate level was determined by Herron[7] to be 22 p.p.b.

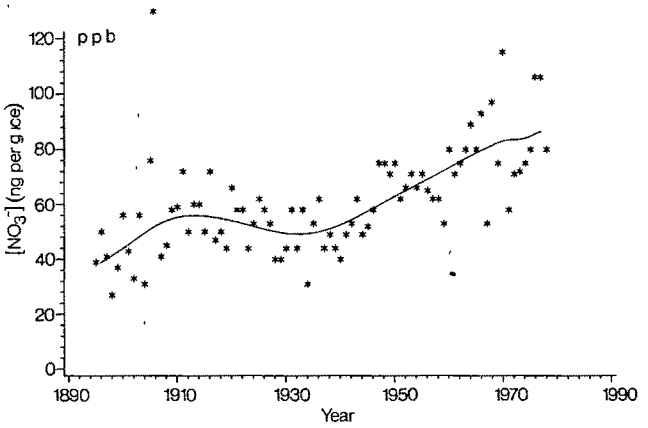

Fig. 1 Annual $[NO_3^-]$ in a shallow core from Dye 3, South Greenland. The general trend is shown with a spline-smoothed curve.

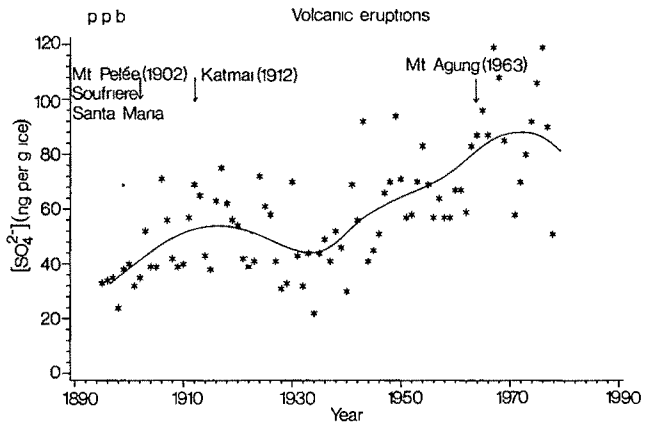

Fig. 2 Annual $[SO_4^{2-}]$ in a shallow core from Dye 3, South Greenland. The general trend is shown with a spline-smoothed curve.

Under unfavourable meteorological conditions the radar station is a possible source of contamination, especially for sulphate. However, the measured $[SO_4^{2-}]$ of 90 p.p.b. for the recent time period 1973–1978 agrees well with Herron's level of 85 p.p.b. for the time period 1975–1981, which was determined in a pit study much further from the Dye 3 station than was our drilling site. Furthermore, our sulphate and nitrate data do not show a discontinuity over the year 1961, when the radar station was constructed. We conclude, therefore, that the contamination attributable to emissions from the radar station is small. We found no indication that the occurrence of melt layers in the Dye 3 firn core influences $[NO_3^-]$ and $[SO_4^{2-}]$.

The nitrate levels measured by Herron[7] are generally slightly higher than ours (Herron's 1884–91, 51 p.p.b., our 1895–1904, 44 p.p.b.; Herron's 1975–81, 114 p.p.b., our 1973–78, 86 p.p.b.). The high nitrate value we found for 1906 is surprising; we cannot exclude contamination of this sample, particularly as $[SO_4^{2-}]$ is also relatively high and in Rasmussen's Dye 3 data[8], $[NO_3^-]$ for 1906 is not elevated. As a consequence of the 1908 Tunguska impact in Siberia, Turco *et al.*[10] have calculated that NO_x concentrations in the lower stratosphere would be elevated by an order of magnitude for a period over 1 yr. The years 1908–10 do not, however, show a higher $[NO_3^-]$, so that the predicted enhancement of $[NO_x]$, if it occurred, did not penetrate into the troposphere. Similar conclusions were reported by Rasmussen *et al.*[8], based on their measurements at Dye 3 and Camp Century.

The concentration depends on three factors: the scavenging process, the transport of air masses from the source to the receptor and the source strength. We ascribe the general trend in anion concentrations to increasing source strength and the short-time fluctuations to the variability in transport processes and scavenging.

Although NO_3^- and SO_4^{2-} are mainly incorporated as HNO_3

and H_2SO_4 in the ice[11-13], HNO_3 and H_2SO_4 are not emitted directly into the atmosphere. The precursors for HNO_3 are NO and NO_2, and for H_2SO_4 are SO_2, dimethyl sulphide (DMS) and H_2S. All these species are oxidized in the atmosphere, either in the gas phase or in cloud droplets[14] to form the two acids, which are then effectively removed by precipitation. The global sources or precursors of HNO_3 and H_2SO_4 are compiled in Table 1. The range of estimates in the literature is large, especially for the natural sources, which cannot be derived from economic data as can the anthropogenic sources. The volcanic contribution is, of course, subject to extreme fluctuation. During the time period covered by our samples, the volcanic activity was low except for the years 1902, 1912 and 1963[15]. With the exception of the already mentioned Katmai explosion, all large eruptions were in the equatorial zone. Their contribution to the sulphate level in our samples is not distinguishable from the scatter.

Inputs from land-based sources to the impurity level in Greenland must travel quite far and must be able to survive in the atmospheric boundary layer, where removal by precipitation is very effective. Sources in the free troposphere or in the ocean surrounding Greenland will contribute more easily to the concentration in the precipitation of South Greenland. Essentially all anthropogenic sources are land-based with the exception of jet airplanes.

Using the estimated source strengths of the different NO_3^- and SO_4^{2-} precursors, one can calculate the percentage of the '1900 level' of $[NO_3^-]$ and $[SO_4^{2-}]$ that is derived from land-based sources. Our calculation assumes that the different sources contribute linearly to the impurity level in the snow and are split into continental (land-based) and other (non-land-based) sources. No interhemispherical mixing is assumed. Two time periods, 1895–1901 and 1973–78, were considered, assuming the emission rates indicated in Table 1 and using the mean measured concentration of these time intervals.

The '1900 level' may be expressed as $\gamma P_C + \delta P_O = C_{1900}$; the 'recent level' as $\gamma(P_C + P_A) + \delta P_O = C_{recent}$, where γ and δ are factors linking emission rates and firn concentration; P_C, P_A and P_O are the land-based (continental), anthropogenic (~1975) and non-land-based (ocean) production rates, respectively; and C_{1900} and C_{recent} are the '1900' and 'recent' firn concentrations, respectively.

This model is no more than a first approximation. Natural sources are diffuse, whereas the anthropogenic components have more the character of point sources. The results of this model calculation give for the 1900 level a contribution of land-based sources to the concentration in the ice of 54% for sulphate and 37% for nitrate. It should be pointed out that this number depends strongly on the emission rates that we have selected in Table 1.

Table 1 Global emission ranges

Sulphur source		Northern Hemisphere range (Tg S yr^{-1})	Southern Hemisphere range (Tg S yr^{-1})
Natural·	Biogenic sea	14–32	18–40
	Biogenic land	2–74 (32)*	1–36
	Volcanoes	0 6–6 (3)*	0 4–4
Man-made:	(1976)	69–98 (98)*	5–6
Nitrogen source			
Natural:	Soil	0.7–7 (4)†	0.3–3
	Wildfire	0.2–0.6 (0 4)†	0.1–0.3
	Ox. NH_3	0–3 (1.9)†	0–2
	Biomass burn.	3–8 (5.5)†	
	Lightning	1–4	1–4
	Stratosphere	0.15–0 45	0.1–0 45
Man-made:	Fossil fuel	7–17 (13)†	0.5–1
	Biomass burn.	6–40 (18)†	6–18
	Jets	0.2–0.4 (0 3)†	<0.1

Data compiled from refs 19–24.

* Assumed production for calculations. natural production land-based, 35 Tg yr^{-1} (≈total land-based production pre-industrial), natural and man-made production land-based, 133 Tg yr^{-1}.

† Assumed production for calculations: natural production land-based, 11.4 Tg yr^{-1} (≈total land-based production pre-industrial), natural and man-made production land-based, 43 Tg yr^{-1}

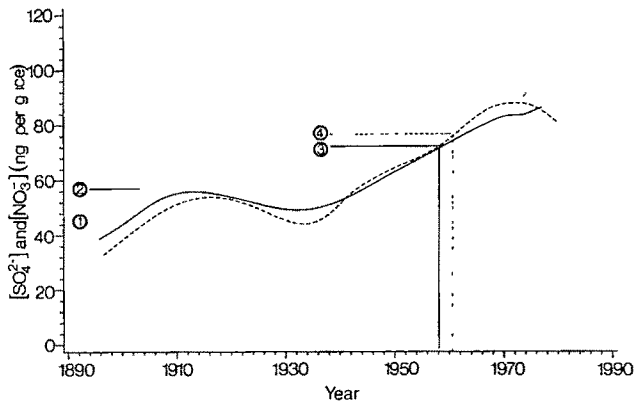

Fig. 3 Time development of atmospheric load with nitrate(—) and sulphate (- - - -) Comparison of anthropogenic and natural input. (1) '1900' $[SO_4^{2-}]$ $(+1\sigma)$ (2) '1900' $[NO_3^-]$ $(+1\sigma)$. (3) '1900' $[NO_3^-]$ $(+1\sigma)+16$ p.p.b. (≈11 Tg N yr^{-1} anthropogenic emission) for when anthropogenic N sources were approximately equal to global natural N sources. (4) '1900' $[SO_4^{2-}]$ $(+1\sigma)+28$ p.p.b. (≈57 Tg S yr^{-1} anthropogenic emission) for when anthropogenic S sources were approximately equal to global natural S sources.

Based on our calculation, 1 Tg yr^{-1} of land-based sulphur source corresponds in the mean annual concentration of the snow in Dye 3 to an additional $[SO_4^{2-}]$ of ~0.6 p.p.b., whereas 1 Tg yr^{-1} of land-based nitrogen source corresponds to ~1.4 p.p.b. of additional $[NO_3^-]$, respectively. These numbers depend only weakly on the assumed emission rates. Thus, the source distribution and the long-range transport of the sulphur and nitrogen components seem to be different. Our data suggest that the nitrogen component is more easily transported through the boundary layer than is the sulphur component, which seems to be contrary to the calculation published by Rhode *et al.*[16]. However, their calculation was based on precipitation data from the European Air Chemistry Network, whereas our data apply to Greenland. The low proportion of the land-based contribution to the pre-industrial $[NO_3^-]$ supports the idea that NO_x from the stratosphere and produced by lightning are the main sources of the background nitrate in remote regions[6,17]. Such sources in the free troposphere were also postulated by Huebert and Lazrus[18] to explain their $[HNO_3]$ measurements in the free troposphere.

Our sulphate concentration in the period 1895–1904 is higher than the values given by Herron[7] for earlier periods. Because volcanic activity was low during 1895–1904, our higher measured concentration indicates that by this time the sulphate level was already considerably elevated over pre-industrial values, possibly reflecting early industrial activity. Our model is inconsistent with the pre-industrial sulphate level given by Herron (22 p.p.b.) and would require a land contribution of over 100%. The most probable explanation is that the natural land-based source used in our model is an overestimate.

Using the relation given above between concentration increase in the ice and source strength, we can deduce the time when anthropogenic sources surpassed the natural source concentration given in Table 1. Figure 3, illustrating this behaviour, shows that the anthropogenic sources started to dominate the total natural sources around 1960. This agrees with the anthropogenic emission data for sulphate given by Möller[19].

Our data suggest that man-made pollution had already started to affect remote regions more than 30 yr ago. The nitrate and sulphate concentrations in Greenland contain information which can ultimately be used to interpret the development and

distribution of sources of acid rain, although at the moment our understanding of source strengths and transport is still so rudimentary that the interpretation must remain largely qualitative. More widespread drilling of firn cores in polar regions would allow the historical development of the acid deposition pattern to be established and sophisticated source receptor models to be tested. Nevertheless, the data already show that human activity drastically changed the atmospheric load of the acidic trace species HNO_3 and H_2SO_4. This fact emerges more clearly in the historical record from remote locations, such as Dye 3, than from direct measurements in populated areas which are influenced by changes in measuring technique and changed local distribution of pollution with time.

We thank W. Bernhard and M. Andrée for assistance during the field work, and W. Dansgaard and H. Clausen from the Geophysical Isotope Laboratory in Copenhagen for the measurements of the $\delta^{18}O$ samples. M. M. Herron reviewed the manuscript and helped to improve it substantially. This work was supported by the Swiss NSF.

Late Eocene microtektites and radiolarian extinctions on Barbados

Annika Sanfilippo*, W. R. Riedel*, B. P. Glass† & F. T. Kyte‡

A late Eocene microtektite layer has been found in three exposed sections on Barbados, West Indies. These microtektites and associated tektite fragments are compositionally similar to the North American tektites and thus, like the Caribbean and Gulf of Mexico microtektites, may belong to the strewn field of 'North American' microtektites which have been found in deep-sea deposits from the Caribbean Sea, across the Pacific and into the northeastern Indian Ocean[1,2]. The 'North American' layer has been reported to be approximately synchronous with several radiolarian extinctions[3,4] and with an anomaly in iridium concentrations[5-7], and it has been hypothesized that the microtektites, the extinctions and the iridium anomaly are all related to an asteroid impact. We report here that the radiolarian extinctions predate the microtektite layer and that the highest Ir concentrations apparently coincide with the extinctions. Thus, although the extinctions may be causally related to the Ir anomaly, the microtektites appear not to be.

Table 1 Major oxide composition of selected Barbados microtektites and tektite fragments and North American tektites

Sample no.	SiO_2	Al_2O_3	FeO	MgO	CaO	Na_2O	K_2O	TiO_2

B-6	76.25	13.49	3.98	0.74	0.74	1.63	2.22	0.74

The data for North American tektite samples BM, B-50 and B-6 are from ref. 14. The rest of the data were obtained by energy dispersive X-ray analysis. A total of 18 microtektites and five tektite fragments from Bath Cliff were analysed.

Microtektites belonging to two Quaternary tektite-strewn fields on land, the Australasian and Ivory Coast, have been found in deep-sea sediment cores taken in the Australasian/Indonesian region and off the Ivory Coast, respectively[1]. Much older than the Quaternary group are the late-Eocene North American microtektites, found in a low-latitude band stretching from the Caribbean to the northeastern Indian Ocean. The glassy rounded tektites and microtektites are believed to be produced by impacts[8,9]. Correlation of late-Eocene microtektites, anomalous Ir, and radiolarian extinctions[6,7] has been used to suggest a relationship between impacts and extinctions similar to that which has been inferred for the Cretaceous-Tertiary event[10].

Recent detailed biostratigraphical investigations on Barbados[11] provided the possibility of locating, on land, the stratigraphical level of occurrence of the microtektites, which had previously been available in only very limited amounts, at scattered localities, in deep-sea cores. The stratigraphical resolution attainable in these land-based sections is 2-10 times greater than that attained in deep-sea sediment cores containing the microtektite layer. For example, the stratigraphical interval separating the earliest occurrence of the radiolarian *Thyrsocyrtis bromia* and the evolutionary transition of *Lithocyclia aristotelis* to *L. angusta* is 100-110 m at Bath Cliff, 10-20 m at Deep Sea Drilling Project Site 149 (ref. 12), about 10 m at DSDP Site 543 (unpublished data) and 15-45 m at DSDP Site 94 (ref. 13). The microtektites were found in this interval at a single stratigraphical level (10-30 cm thick) in three sections; Bath Cliff, Gay's Cove North and Gay's Cove South.

All three sections were sampled continuously, by taking contiguous samples 5 cm thick. This provided a basis for examining changes in the microtektites throughout their occurrence, and details of the abundances in the uppermost parts of the ranges of radiolarian species as they became extinct. Weighed subsamples of the channel samples were disaggregated and sieved to obtain the >63-μm fraction for investigation of the radiolarians and the microtektites.

Identification of the Barbadian microtektites and tektite fragments as belonging to the late-Eocene horizon which has been called the 'North American' strewn field is indicated by their late Eocene age and by their chemical composition (Table 1). North American tektites are characterized by low lime and magnesia content as compared with tektites from other strewn fields[14], and this is reflected in the composition of the Barbados microtektites and tektite fragments. They have a unimodal size distribution, this being more pronounced in the samples near

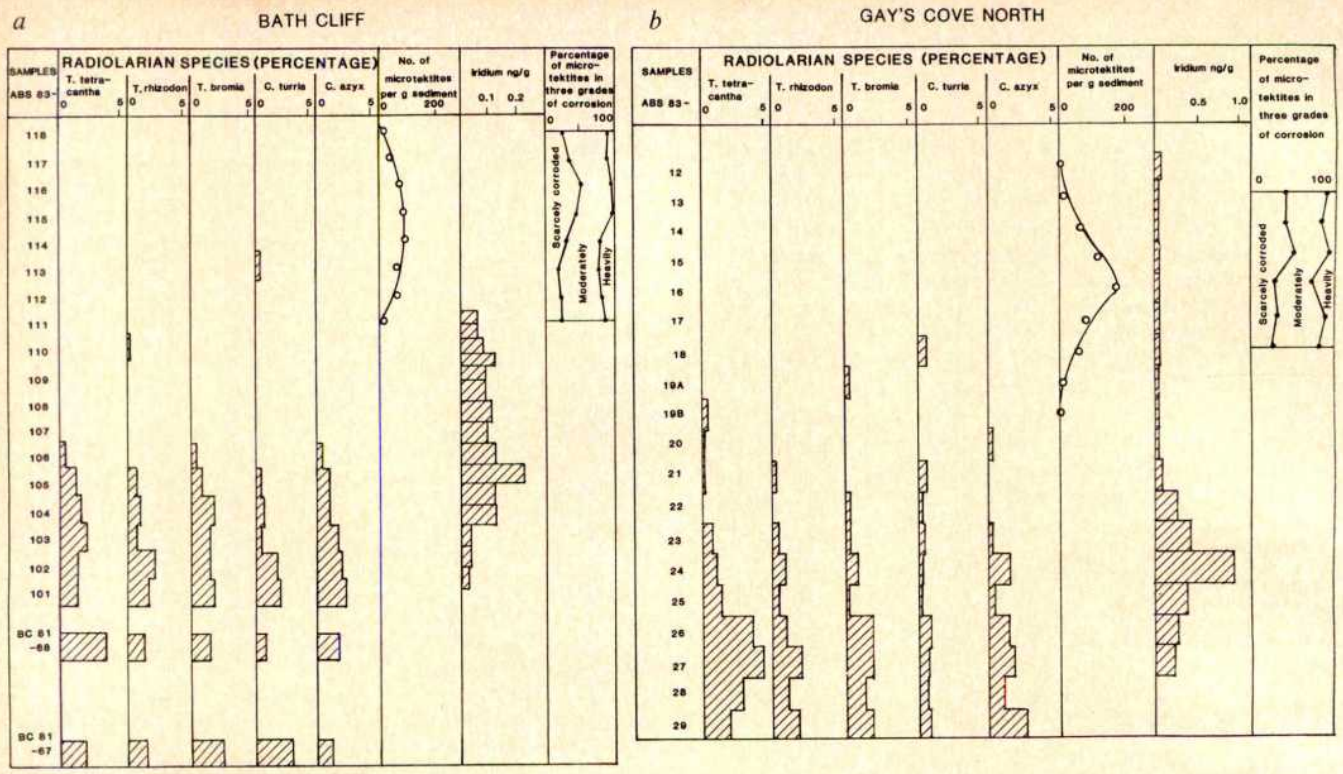

Fig. 1 The upper limits, in the Bath Cliff (*a*) and Gay's Cove North (*b*) sections, of species that became extinct slightly below the microtektite layer. Abundances are given as percentages of the total assemblage coarser than 63 μm, estimated from assemblages of 6,000–26,000 radiolarians from each sample. Although the five radiolarian species plotted constitute a high proportion of the 20 or so commonly used for late-Eocene/early-Oligocene stratigraphy, the proportion is less remarkable when considered in relation to the 200–300 additional species present in these assemblages but not used stratigraphically. In the right-hand columns are numbers of microtektites and their degree of corrosion, and Ir concentrations. In each section, the extinctions clearly predate the microtektite event, and coincide with the high Ir concentrations.

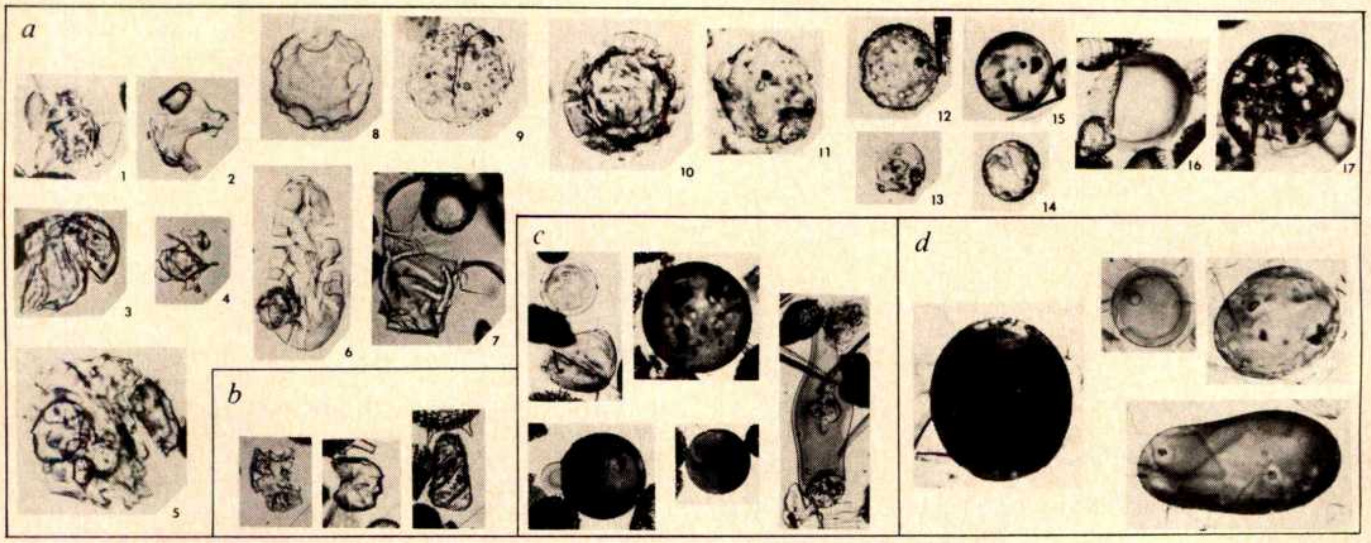

Fig. 2 Representative examples of microtektites from: *a*, Barbados; *b*, DSDP Site 543; *c*, DSDP Site 149; and *d*, DSDP Site 94. In *a*, specimens 15–17 were counted as smooth, regular; specimens 8–14 as moderate; and 1–7 as highly irregular. Magnification ×105.

the middle of the layer than towards its limits. The 80–100-μm and 100–120-μm size grades contain more specimens than do the other 20-μm increments, but the greatest volume of material is in the slightly larger size grades. Assuming a grain bulk density of 2.5 g cm^{-3} for both the sediment and the tektite material and an average bulk dry density of 1.32 g cm^{-3} for the sediment[11], the net fluence of microtektites and tektite fragments is 45 tonnes km^{-2} at the Bath Cliff section. Although the thicknesses of the layer at Gay's Cove North and Gay's Cove South is less certain because of imprecise relations between the line of sampling and the attitude of the beds (resulting from local small-scale tectonic complications), the total tektite contribution appears to be greater, perhaps as much as 80 tonnes km^{-2} in the former section and 100 tonnes km^{-2} at the latter.

This is substantially less than the 1,000 tonnes km^{-2} calculated for Caribbean and Gulf of Mexico sites[3]. The lower figures for Barbados may indicate that this site is closer to the edge of the strewn field. Another factor is that the Barbados microtektites are now above sea level and have probably experienced more solution than the microtektites from the submarine localities.

In an attempt to detect the iridium anomaly reported just below the main microtektite layer by Ganapathy[6], and coincident with it by Alvarez *et al.*[7], neutron activation analysis was performed on a continuous series of Bath Cliff samples from about 5 cm above the base of the layer to 25 cm stratigraphically below it, and on a continuous series of Gay's Cove North samples from about 15 cm stratigraphically above the microtektite peak to about 30 cm below it. The results show a peak in Ir concentration well below the microtektite layer and at practically the same level as the radiolarian extinctions in both sections (Fig. 1*a*, *b*), but it represents a substantially lower net fluence of Ir (<2 ng cm^{-2} at Bath Cliff and ~ 7 ng cm^{-2} at Gay's Cove North) than would be expected on the basis of results obtained by Ganapathy[6] (63 ng cm^{-2}). Our data, like Ganapathy's, would indicate that the anomalous Ir is not coincident with the North American microtektite layer, but we cannot rule out a relationship between the radiolarian extinctions and another impact event. Clinopyroxene-bearing glass spherules (as distinct from the microtektites) are coincident with the Ir anomaly in core RC9-58 (refs 6, 15). These may have once existed at the level at which we found the Ir, and have since been dissolved by ground water above sea level.

The radiolarian extinctions clearly predate the microtektite layer in these sections (Fig. 1). Their apparent synchroneity in sections investigated earlier may be due to much lower rates of sediment accumulation and thus lower stratigraphical resolution. The tailing-upward of the radiolarian species could be attributable to bioturbation[16] (and the times of their extinction pinpointed at slightly above the levels at which their abundances begin markedly to decline). However, bioturbation does not provide an explanation for the separation between the microtektites and the extinctions. At Bath Cliff, the separation of ~ 27 cm probably represents an interval of 13,000–14,000 yr. This is based on an estimated sediment accumulation rate of ~ 20 m Myr^{-1} (calculated from separation of biostratigraphical events)[11,17]. This contradicts any causal relationship between the extinctions and the late-Eocene microtektite event[6,7].

Although compositional similarities and stratigraphical position imply a correlation between the Barbadian microtektites and the North American field, there are differences that may reflect variations within the field. Texturally, these samples range from regular spheres and teardrops to highly corroded or angular fragments. The proportion of fragments appears to be much greater in Barbados and at DSDP Site 543 (generally $>60\%$, Fig. 2*a*, *b*) than in the Caribbean and Gulf of Mexico sites ($<8\%$ (ref. 4); Fig. 2*c*, *d*). Moreover, the Barbadian microtektites have a slightly higher SiO_2 content and have a generally paler colour than those from the Caribbean and Gulf of Mexico. Keller *et al.*[18] have suggested that there may be multiple late-Eocene microtektite layers, not associated with profound changes in the biota, but this cannot be evaluated here. The basic question of the multiple falls will ultimately be resolved by careful description of the physical, chemical and isotope characteristics of the microtektites at each of their occurrences and by their placement in a more precise biostratigraphical framework[19,20].

We thank J. B. Saunders, R. C. Speed and R. Torrini Jr, for guidance in the field, to D. Riedel for assistance in the collecting and initial processing of samples, and to L. H. Barker, Chief Geologist of the National Petroleum Corporation of Barbados, for his interest in this work. Financial support (grant nos OCE82-19836, OCE84-10177 and OCE82-08197) and DSDP samples were provided by the NSF.

Manipulation of the morphogenetic pathways of tobacco explants by oligosaccharins

Kiem Tran Thanh Van, Patrick Toubart & Alain Cousson

CNRS Laboratoire du Phytotron, 91190 Gif sur Yvette, France

Alan G. Darvill, David J. Gollin, Paulanne Chelf & Peter Albersheim

Department of Chemistry and Department of Molecular, Cellular and Developmental Biology, Campus Box 215, University of Colorado, Boulder, Colorado 80309, USA

Acquiring the ability to regulate morphogenesis in plants has long been an elusive goal. Previous research has established that 'thin cell-layer' explants from the surface of the floral branches of tobacco can be induced to form either callus, vegetative buds, flowers or roots by adjusting the *p*H and the ratio of auxin to cytokinin in the culture medium[1–5]. We now report that oligosaccharins (oligosaccharides with regulatory activity) derived from plant cell walls can, at concentrations of $\sim 10^{-8}$ or 10^{-9} M, induce tobacco explants to form vegetative buds instead of flowers or callus, or flowers instead of vegetative buds. Other oligosaccharins can induce the explants to form roots instead of vegetative buds. This ability of oligosaccharins to control morphogenesis suggests that these fragments are *in situ* regulators of morphogenesis.

Tissue cultures of some plant species have been induced to form vegetative buds and/or roots by varying the relative concentration of growth regulators (for example, auxin and cytokinin)[1]. Despite extensive trials with various concentrations of growth regulators, carbohydrates and mineral salts, however, it remains difficult to induce tissue cultures of many plant species to form organs. Tissue cultures of those plant species that can be induced by means of varying the ouxin/cytokinin ratio usually form only vegetative buds, roots, or undifferentiated callus. Besides altering the concentration of these two growth regulators, adding sucrose or glucose[2,3] and varying the *p*H of the culture medium[4,5] are two other factors that have been shown to affect organ formation in tobacco tissue culture. Moreover, cultured tissues with organized cells (for example, epidermis, subepidermis) may have greatly increased capacities to form organs[6–10]. The ability to control morphogenesis in tissues has been particularly well developed in 'thin cell-layer' explants of tobacco[9,11,12]. We have used this system for our experiments.

The tobacco explants are obtained by excising cortical tissue of floral branches in 1×10-mm strips containing epidermis (1 cell layer), subepidermis (1 cell layer) and parenchyma (1–3 cell layers). When these thin cell-layer strips, or 'tobacco explants' as we will call them, are floated on liquid culture media containing salts, glucose (as an energy source), auxin (indolebutyric acid) and cytokinin (kinetin), and when the *p*H of the culture medium is adjusted to a specific value, the explants are induced to form flowers, vegetative buds, roots or undifferentiated callus. Thus, exogenously applied factors determine the specific type of organ formed by the explants.

Table 1 Effect of EPG fragments on morphogenesis of tobacco explants

	Concentration of EPG fragments ($\mu g\ ml^{-1}$)	Flowers	Vegetative buds	Callus formation
Medium I	0	600*	0	0
*p*H 3.8	1	100	1,800	0
Medium II	0	0	0	100%
*p*H 5.0	1	0	400	0
	10	0	1,200	0
*p*H 6.0	0	0	1,800	0
	1	600	18	0

* Total number of organs (flowers, floral shoots, vegetative buds or roots) formed or percentage of explants exhibiting callus formation (cell proliferation without organogenesis) in three separate experiments. The numbers are the sums in each experiment of the organs on 20 explants.

Methods. Tobacco plants were cultured at 24 °C under a 16-h photoperiod of natural light, complemented by artificial light (25 $W\ m^{-2}$) when the natural light was $< 50\ W\ m^{-2}$. The artificial light was a mixture of fluorescent (Mazda-type 65 W) and incandescent (60 W). Relative humidity was maintained at 65%. The tobacco explants were excised from basal parts of floral branches of *Nicotiana tabacum* L. c.v. samsun when the inflorescence contained 20 green fruits. The terminal green fruit of the cyme was 2.0–2.3 cm long and ~1.2 cm in diameter. The explants were obtained from floral branches that had been surface-sterilized (7% $Ca(OCl)_2$ for 10 min) and then rinsed three times in sterile water. Twenty explants were floated on liquid medium (40 ml) in Petri dishes (10 cm). The dishes were sealed with Parafilm. The basal medium was composed of Murashige and Skoog's macro- and micro-elements[29], *myo*-inositol (100 mg l^{-1}), thiamine-HCl (0.4 mg l^{-1}) and glucose (30 g l^{-1}). Kinetin was added at 5×10^{-7} M and indolebutyric acid (IBA) at 5×10^{-7} M in medium I and at 3×10^{-6} M in medium II. Each medium was adjusted to the specified *p*H with either HCl or KOH. Oligosaccharin mixtures (1 or 10 $\mu g\ ml^{-1}$) were added (the addition of the oligosaccharins did not alter the *p*H of the media). Each medium was sterilized by passing it through a Millipore filter (0.2 μm). The explants were incubated at 24 °C and under continuous light (20 $W\ m^{-2}$). After 30 days, the morphogenesis of the explants was assessed. Each experiment was repeated three or four times. The results presented here are a summary of the data collected in all of these experiments. Two different mixtures of sycamore cell wall fragments (oligosaccharins) were used. One set of oligosaccharins (EPG fragments) was released by endo-α-1,4-polygalacturonase treatment of isolated sycamore cell walls. Endopolygalacturonase was purified as described elsewhere[30], as were the cell walls[31]. The cell walls were treated with the enzyme and the solubilized fragments were isolated as described elsewhere[32], except that the *p*H of the fragments was adjusted to 6.5 before the final exhaustive dialysis against deionized water. The second mixture of sycamore cell wall fragments was prepared by partial base-catalysed solubilization and partial degradation of cell wall components. These B fragments were prepared as follows: 4 MKOH (500 ml), containing $NaBH_4$ (500 mg) was added to isolated sycamore cell walls (5 g). The suspension was stirred overnight and then passed through two layers of Whatman GF/A filter paper. While being vigorously stirred, the soluble material was adjusted to *p*H 6.5 with concentrated HCl. The solvent was evaporated at 40 °C under reduced pressure. The supernatant solution was decanted repeatedly from salt crystals that formed in the evaporation flask. The salt crystals were washed with a small volume of distilled water and the washes were added to the supernatant. Once the volume of the supernatant had been reduced to < 80 ml, the preparation was desalted on a large Sephadex G-10 column (~600 ml bed volume) eluted with distilled water. The carbohydrate-positive fractions (determined by the anthrone colorimetric assay[33]) with low conductivity (low salt) were pooled and then dried under reduced pressure at 40 °C. Methanol (200 ml) was added to the residue and evaporated, twice. Then methanol containing 10% acetic acid (300 ml) was added and dried and this procedure was repeated three times. Finally, methanol (200 ml) was added and the residue was dried three times. These evaporations were performed to volatilize the methyl ester of borate. The residue was dissolved in distilled water, the *p*H adjusted to 7.0 and the solution lyophilized.

It would be difficult to study the biochemical and molecular genetic phenomena underlying induced morphogenesis in these tissues because auxin and cytokinin are both pleiotropic growth regulators; that is, they have many effects on plant tissues besides influencing morphogenesis. Furthermore, altering the *p*H of the culture medium is also likely to have effects on such diverse factors as the biochemical properties of the cell wall and the ability of the plasma membrane to perceive and transport plant growth regulators[13,14], salts[15] and other metabolites[16,17]. We hypothesize that auxin, cytokinin and the *p*H of the culture medium affect the release of, processing of and/or responsiveness to chemical messages, each of which is not broadly pleiotropic and each of which regulates a delineated set of biochemical processes that regulate morphogenesis[4,18–20]. The experiments described here were designed to obtain evidence for the existence of chemical messages that have more specific effects than do the classical plant growth regulators.

Certain oligosaccharides, derived by means of fragmenting plant cell wall polysaccharides, are chemical messages that have been shown to be capable of regulating physiological processes in plants (for example, refs 18, 21–26 and S. Doares, A.G.D. and P.A., unpublished results). Oligosaccharides capable of regulating physiological processes have been called oligosaccharins[27]. The discovery that oligosaccharins can control gene expression in plants motivated us to design the present experiments (see Table 1, methods), which demonstrate that oligosaccharins derived from the cell walls of suspension-cultured sycamore cells can regulate the morphogenesis of the thin cell-layer explants of tobacco.

The tobacco explants, when grown in medium I at *p*H 3.8, formed an average of 10 flowers each (Table 1). Adding 1 $\mu g\ ml^{-1}$ of EPG fragments (oligosaccharins released by endo-α-1,4-polygalacturonase treatment of sycamore cell walls) inhibited flowering by 87% and induced the explants to form many vegetative buds over the entire surface area. (Flowers formed only on the basipetal end of the explants.) In medium II at *p*H 5.0, in the absence of added EPG fragments, the explants developed, not organs, but rather, large amounts of undifferentiated callus. The formation of callus was inhibited by 1 or 10 $\mu g\ ml^{-1}$ of EPG fragments and the formation of large numbers of vegetative buds was induced by EPG fragments. In medium II at *p*H 6.0, in the absence of added fragments, the explants formed vegetative buds. However, formation of buds was almost completely inhibited and, instead, formation of flowers was induced by adding 1 $\mu g\ ml^{-1}$ of EPG fragments.

The base-solubilized (B) fragments have an effect similar to that of the EPG fragments in medium I at *p*H 3.8 (Table 2). Although the B fragments did induce formation of vegetative buds and inhibit flowering, 10 $\mu g\ ml^{-1}$ of the B fragments was required, compared with the 1 $\mu g\ ml^{-1}$ of EPG fragments required in the previous example. Furthermore, B fragments caused the explants to form floral shoots, rather than flowers, on the same explants that formed vegetative buds. In medium II at *p*H 6.0, these B fragments, like the EPG fragments, inhibited vegetative bud formation; but the B fragments induced roots, rather than flowers, to form.

Table 2 Effect of B fragments on morphogenesis of tobacco explants

	Concentration of B fragments ($\mu g\ ml^{-1}$)	Flowers	Floral shoots	Vegetative buds	Roots	Callus
Medium I	0	600*	0	0	0	0
*p*H 3.8	1	600	300	27	0	0
	10	0	300	1,200	0	0
Medium II	0	0	0	0	0	100%
*p*H 5.0	1	0	0	0	300	100%
	10	0	0	0	420	100%
*p*H 6.0	0	0	0	1,800	0	0
	1	0	0	0	420	100%
	10	0	0	0	450	100%

* See Table 1 legend.

We estimate the concentration of active oligosaccharins in the EPG and B fragment mixtures to be 10^{-8} or 10^{-9} M, which matches the specific activity observed for other oligosaccharins[22,28]. Also, like the other oligosaccharins[21], the EPG and B fragments exhibit activity over a rather narrow (one or two orders of magnitude) range of concentration; the morphogenetic effects disappear when the concentration is too high or too low (unpublished data). Furthermore, the EPG and B fragments exhibit the described effects in the presence of 30 mg ml^{-1} of glucose.

Thus the effect of the EPG and B fragments on morphogenesis does not result from a nonspecific carbohydrate effect. The ability of oligosaccharins to regulate morphogenesis in tobacco explants makes apparent the possibility that these fragments are *in situ* regulators of morphogenesis. Our goal is to ascertain whether this is, or is not, the case.

The enzyme ribulose 1,5-bisphosphate carboxylase-oxygenase (RuBPCase) has a pivotal role in photosynthetic organisms, catalysing the first reactions of the interlocked but opposing pathways of photosynthesis and photorespiration[1,2]. The agricultural interest in RuBPCase centres on the possibility of altering the structure of the enzyme to improve net photosynthetic yield, but such studies are hampered by the structural complexity of the hexadecameric holoenzyme in plants which prevents *in vitro* dissociation and reconstitution, apparently due to the properties of the large subunits[3,4]. We have chosen to express the large and small subunit genes of the cyanobacterium *Synechococcus* PCC6301 in *Escherichia coli* to develop an experimental system in which structural changes introduced into RuBPCase polypeptides could be assessed following subunit assembly. The cyanobacteria (blue-green algae) are autotrophic prokaryotes which have a plant-like photosynthetic mechanism and RuBPCase structure[5,6]. We report here the synthesis of an active RuBPCase in *E. coli* which contains both large and small subunit polypeptides.

The genes for the large subunit (L) and small subunit (S) of RuBPCase from *Synechococcus* have been identified on a 2.17-kilobase (kb) *Pst*I fragment of DNA[7,8]. To obtain expression of both L and S genes, this *Pst*I fragment was cloned into the *Pst*I site of the plasmid pLa2311 (ref. 9) downstream from a λ P_L promoter, to yield plasmid pSV55 (Fig. 1*a*). To demonstrate that RuBPCase polypeptides could be synthesized following derepression of P_L, a culture of *E. coli* cells containing pSV55 was incubated at 41 °C and a protein extract prepared. Electrophoresis of the total cell proteins in polyacrylamide gels containing SDS, followed by Western blotting using anti-wheat RuBPCase serum, revealed the presence of two immunoreacting polypeptides (Fig. 1*b*, lane 2). The smaller polypeptide has a relative molecular mass (M_r) of 52,000 and co-migrates with L present in maize leaf extracts (Fig. 1*b*, lane 3). The larger polypeptide of M_r 70,000–72,000 is a fusion protein between the 181 N-terminal amino acids of β-lactamase[10] and L. The detection of both polypeptides was dependent on transcription from P_L; in repressed conditions neither was observed (Fig. 1*b*, lane 1), nor if the orientation of the genes was reversed with respect to P_L (data not shown). *Synechococcus* S could not be identified in Fig. 1*b*, lane 2, when using anti-wheat RuBPCase serum because of the greater evolutionary divergence of S compared with L polypeptides. To demonstrate S synthesis, derepressed *E. coli* cells containing pSV55 were labelled with ^{35}S-methionine and the assembled soluble enzyme complex was separated from unassembled subunits by gel filtration, then reacted with anti-wheat RuBPCase. The immune complex was adsorbed to protein A–Sepharose, thus trapping assembled S via binding to L, which in turn interacts with IgG and protein A. Figure 1, lane 4, shows that both L and S are present together in a subunit complex excluded from a Biogel P-300 column (exclusion limit 400,000 M_r).

It has been shown that the presence of both S and L are essential for the catalytic function of *Synechococcus* RuBPCase[11]. The soluble fractions of sonicated *E. coli* cells containing pSV55, with or without induction, were prepared and used to measure RuBPCase activity. Figure 2*a* shows the results of assaying for RuBP-dependent incorporation of $^{14}CO_2$ into acid-stable products. Induced cell extracts show a linearity of ^{14}C incorporation with time and a specific activity of 8 nmol CO_2 fixed per min per mg soluble protein at 30 °C. In contrast, the uninduced cell extract contains no detectable RuBPCase activity. The RuBPCase activity present in induced cell extracts can be inhibited by the addition of anti-wheat RuBPCase serum before assay (Fig. 2*b*). To confirm that RuBPCase activity was dependent on the presence of S, the following deletion experiment was devised. The 2.17-kb *Pst*I fragment was transferred from pSV55 to the *Pst*I site of pUC9 (ref. 12) in the appropriate orientation for the L and S genes to be transcribed from the *lac* promoter. The resulting plasmid, pDB50, when induced with isopropyl β-D-thiogalactoside, gave a specific activity for RuBPCase of 14 nmol CO_2 fixed per min per mg soluble protein at 30 °C when assayed as described in Fig. 2 legend. Plasmid

Present address: Institute for Enzyme Research, University of Wisconsin, Madison, Wisconsin 3705, USA.

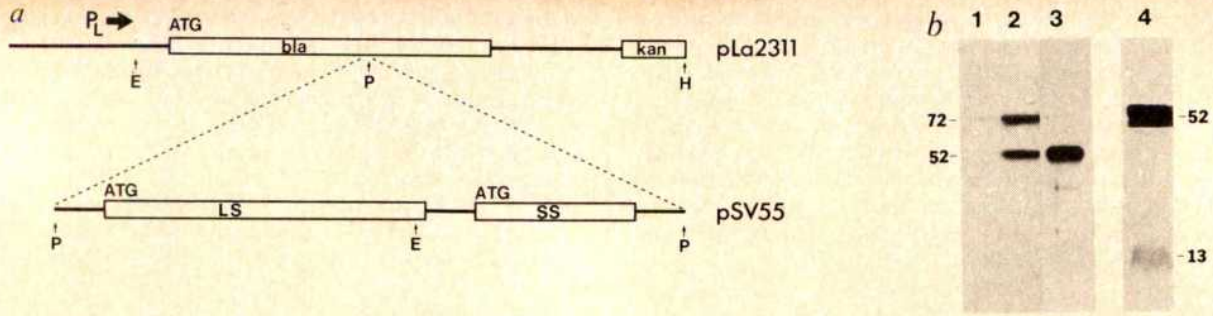

Fig. 1 *a*, Construction of RuBPCase expression plasmids. There are asymmetrical *Eco*RI sites in the vector and insert. The plasmid in which the insert is orientated for RuBPCase gene transcription from P_L is designated pSV55. The position of the *Pst*I (P), *Eco*RI (E) and *Hin*dIII (H) sites are indicated, together with the large subunit (LS), small subunit (SS) and β-lactamase (*bla*) genes with their initiator methionine (ATG) marked. The direction of transcription from the P_L promoter is shown with an arrow. *b*, Analysis of RuBPCase polypeptide synthesis in M5219 cells containing pSV55 plasmid. Lane 1, total protein of uninduced pSV55 (Western blot); lane 2, total protein of induced pSV55 (Western blot); lane 3, total maize leaf protein (Western blot); lane 4, immunoadsorbed pSV55-encoded L and S polypeptides labelled with ^{35}S *in vivo*.

Methods. *a*, The *Synechococcus* RuBPCase L and S genes are present on a 2.17-kb *Pst*I fragment in the clone pLS506 (ref. 8). The pLS506 plasmid was digested with *Pst*I and ligated into the P_L expression plasmid pLa2311 (ref. 9), previously linearized with *Pst*I at a site within the ampicillin-resistance gene. The kanamycin-selectable marker on pLa2311 was retained intact. The ligation mixture was transformed into strain M5219 [M72*lacZ*am*trp*amSm^R(λ*bio*252*c*I857ΔH1)] (ref. 9) and kanamycin-resistant colonies selected. Ampicillin-sensitive colonies containing the 2.17-kb *Pst*I insert were digested with *Eco*RI to identify clones with the two possible orientations of the fragment. *b*, To detect LS synthesis, M5219 cells containing pSV55 were grown at 30 °C in 100 ml of L broth containing 50 μg ml^{-1} kanamycin to $A_{600} = 0.4$. Cells were induced at 45 °C for 10 min and then cultured at 41 °C for 2 h with vigorous shaking. Uninduced controls were maintained at 30 °C. Cells were collected by centrifugation and incubated for 30 min on ice in 0.5 ml of 10 mM Tris-HCl *p*H 8.0, 10 mM EDTA, 1 mg ml^{-1} lysozyme. The solution was sonicated for 30 s, mixed with 0.5 ml 10% (w/v) SDS and incubated at 25 °C for 10 min. A soluble fraction was recovered after centrifugation in an Eppendorf microcentrifuge for 15 min. Maize leaf proteins were isolated by grinding 1 g of young tissue with 3 ml of 100 mM Tris-HCl *p*H 8.0, 20 mM $MgCl_2$, 10 mM $NaHCO_3$, 5 mM EDTA, 1 mM β-mercaptoethanol and 2% (w/v) insoluble polyvinylpyrrolidone (PVP; buffer A). The homogenate was clarified using an Eppendorf microcentrifuge for 5 min. Soluble proteins from bacterial and leaf cells were heated in SDS loading buffer and electrophoresed on a 15% polyacrylamide gel containing SDS[19]. Polypeptides were transferred from the gel to nitrocellulose[20], the filters preincubated with 1.5% (w/v) gelatin in 10 mM Tris-HCl *p*H 7.5, 0.35 M NaCl, for 2 h, and then incubated with 25 μl anti-wheat RuBPCase serum overnight in 25 ml 10 mM Tris-HCl *p*H 7.5, 0.15 M NaCl, 0.1% deoxycholate, 0.1% SDS and 1% Triton X-100 (RIA buffer). After washing with RIA buffer, the filter was incubated with 0.5 μCi ^{125}I-protein A for 2 h and then washed in RIA buffer before autoradiography. To detect SS synthesis, a 25-ml culture of K-12ΔH1Δ*trp* cells[9] containing pSV55 was grown in M9 medium containing glucose, tryptophan, biotin and thiamine-HCl to $A_{600} = 0.5$ at 30 °C. The culture was shifted to 42 °C and after 5 min 2 mCi ^{35}S-methionine were added. After 1.5 h at 42 °C, the cells were collected by centrifugation, resuspended in 0.5 ml 25% (w/v) sucrose, 50 mM Tris-HCl *p*H 8.0, 10 mM EDTA, 1 mg ml^{-1} lysozyme for 15 min at 0 °C, and then lysed by the addition of an equal volume of 50 mM Tris-HCl *p*H 8.0, 100 mM NaCl, 10 mM $MgCl_2$, 0.5 mM EDTA, 1 mM β-mercaptoethanol and 0.1% (v/v) Triton X-100 (buffer B). Phenylmethylsulphonyl fluoride was added to 1 mM, the lysate sheared through a hypodermic syringe and then centrifuged at 100,000*g* for 1 h. The supernatant (1 ml) was passed through a 0.9 × 27 cm column of Biogel P-300 (50–100 mesh) in buffer B at 4 °C. The excluded column fractions ($M_r \geqq 400{,}000$) were incubated with anti-wheat RuBPCase and then adsorbed to protein A–Sepharose and washed as before[21,22] in non-denaturing conditions. The adsorbed polypeptides were boiled in SDS sample buffer, resolved by electrophoresis on a 20% polyacrylamide gel containing SDS[19] and fluorographed[23]. Gels were calibrated with ^{14}C-labelled markers as before[21,22].

pDB50 was digested with *Pst*I and partially with *Hin*dIII (see ref. 8) and a resulting 1.7-kb fragment containing only the L gene transferred to the *Pst*I/*Hin*dIII sites of pUC8 (ref. 12), such that the L gene was transcribed from the *lac* promoter. Induction of the resulting plasmid pDB53 did not yield any detectable RuBPCase activity, indicating that S is required for the active enzyme complex to form in *E. coli*. Western blotting confirmed that L synthesis was still directed by pDB53 (data not shown).

For further probing of the active site, the transition-state analogue 2-carboxyarabinitol 1,5-bisphosphate (CABP) was used. This binds to the activated ternary complex $E.CO_2.Me^{2+}$ to give a stable quaternary complex of $E.CO_2.Me^{2+}.CABP$ (ref. 1). A mixture of ^{14}C-labelled diastereomers CABP and 2-carboxyribitol 1,5-bisphosphate (CRBP) were synthesized[13] and then incubated with soluble extracts of control *E. coli* cells, induced cells containing pSV55, or purified spinach RuBPCase. The extracts were passed through affinity columns containing immobilized anti-wheat RuBPCase and the immunoadsorbed protein was eluted with 8 M urea[14]. Column fractions were counted for ^{14}C isotope content and aliquots analysed by Western blotting. In Fig. 3*a*, labelled peaks can be seen for the spinach RuBPCase and the pSV55 extract, but not for the control strain. The labelled analogue binding, together with the antibody column, has therefore allowed the detection of specific binding to the active site of the *Synechococcus* enzyme synthesized in *E. coli*. Figure 3*b* confirms that the protein adsorbed to the column contains the L polypeptide.

RuBPCase isolated from *Synechococcus* has a M_r of 530,000 (ref. 6) with subunit M_rs of 52,470 for L[5] and 14,000 for S[15], and a hexadecameric structure of L_8S_8. To analyse the structural complexity of the enzyme synthesized in *E. coli*, soluble protein extracts from induced cells containing pSV55 were centrifuged on sucrose gradients. The position of the enzyme in the gradient was determined either by RuBPCase activity or by prior labelling of the active site with ^{14}C-labelled CABP/CRBP. The protein samples layered on the gradients contained β-galactosidase as an internal marker, and gradients centrifuged in parallel contained spinach RuBPCase (M_r 550,000), β-galactosidase (465,000), aldolase (160,000) and ovalbumin (43,000). Figure 4*a*, *b* shows that the size of RuBPCase synthesized in *E. coli* is similar to spinach RuBPCase. Sucrose gradient fractions analysed by SDS-gel electrophoresis and Western blotting using anti-wheat RuBPCase serum revealed the presence of the *Synechococcus* L polypeptide in the fractions containing the RuBPCase peak of activity (Fig. 4*c*). There was also some β-lactamase/L fusion protein in the lower part of the gradient, although most of this 72,000-M_r protein is located in the membrane fraction, presumably because of initiation of export by the β-lactamase signal sequence[16]. It does not necessarily follow that a hexadecameric structure is formed in *E. coli*, because the RuBPCase synthesized in the bacteria and spinach leaves is of a similar size, as determined by sucrose gradient centrifugation and by electrophoresis on non-denaturing gels (data not shown). The large size indicates that the L_8 structure is probably formed, but an L_8S_n complex where n is less than 8 would be difficult to resolve because of the small size of S. Although S must be present to obtain an active enzyme[15], we believe that the S

binding sites on the L octamer may not be fully saturated because of two observations. First, we can estimate from ^{14}C-labelled CABP/CRBP binding to L_8S_n complexes on sucrose gradients that these structures comprise about 2% of the *E. coli* soluble proteins and yet the specific activity of RuBPCase in crude extracts is lower than expected. Second, liquid scintillation counting of ^{35}S present in the L and S polypeptides isolated from SDS-polyacrylamide gels (Fig. 1*b*, lane 4) indicates that L_8S_n structures are formed where $n = 2$ or 3. This problem is likely to be resolved by increased production of S relative to L using suitable plasmids.

Previous work has shown that active RuBPCase can be synthesized in *E. coli* using genes from purple non-sulphur bacteria to give either a dimeric L_2 (ref. 17) or a hexameric L_6 (ref. 18) enzyme. These enzymes, however, are atypical in that an S polypeptide is not required for activity. The most common form of the enzyme is the L_8S_8 structure found in plants, and in prokaryotes possessing a Calvin cycle. In the L_8S_8 structures, the presence of S is essential for activity, based on evidence from *Synechococcus*[15] and from our data presented here in which deletion of the S gene abolishes RuBPCase activity. A suggested role for S is that its binding to L induces a conformational change that promotes activity, and so it has an essential but indirect role in catalysis[15]. This report, describing the assembly in *E. coli* of an L_8 structure containing S subunits to enable the enzyme to fix CO_2, represents one of the most complex macromolecular structures to be synthesized using recombinant DNA techniques. The RuBPCase activity is presumably

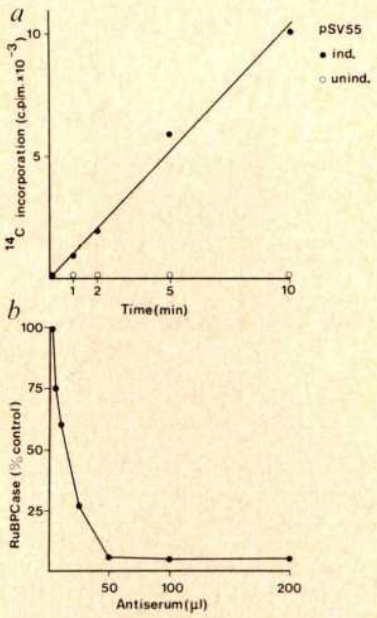

Fig. 2 RuBPCase activity in induced cell extracts of M5219 containing pSV55, and antibody inhibition of enzyme activity. *a*, The linear incorporation of ^{14}C into acid-stable material using RuBP as substrate and plasmid pSV55 in either induced (●) or uninduced (○) M5219 cells. *b*, Increasing inhibition of RuBPCase activity in induced pSV55-containing cell extracts as increasing amounts of anti-wheat RuBPCase serum are added.

Methods. To measure RuBPCase activity, cells were grown in 800 ml of L broth with 50 μg ml^{-1} kanamycin, induced and collected as described in Fig. 1*b*. Cells were resuspended in 1 ml of 100 mM Tris-HCl *p*H 8.0, 20 mM $MgCl_2$, 10 mM $NaHCO_3$, 1 mM EDTA and 1 mM β-mercaptoethanol. Cells were broken by sonication and the extract clarified at 100,000*g* for 1 h. RuBP-dependent ^{14}C incorporation into acid-stable material was assayed using 100-μl aliquots containing 2.7 mg ml^{-1} protein at 30 °C (ref. 11). The activity in an uninduced control was also measured. For antibody inhibition studies, 100-μl aliquots of induced soluble pSV55 extracts were incubated with various amounts of anti-wheat RuBPCase serum overnight at 4 °C. The samples were centrifuged for 15 min in an Eppendorf microcentrifuge and the supernatant used for RuBPCase assay[11].

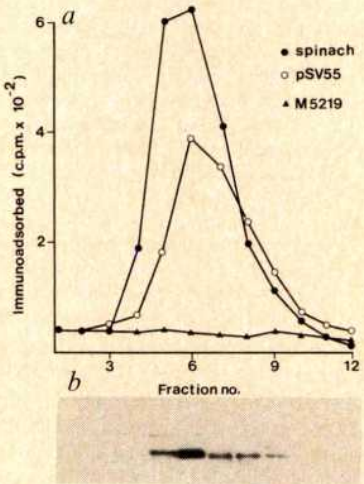

Fig. 3 Affinity column binding of RuBPCase labelled with the transition state substrate analogue ^{14}C-CABP. *a*, The ^{14}C-CABP elution profile of spinach RuBPCase (●), induced pSV55 encoded RuBPCase (○) and control M5219 cell extracts (▲). *b*, Identification of L polypeptide in the column fractions from the pSV55 extract using Western blotting.

Methods. Cell extracts were prepared by sonication as in Fig. 2, using either induced M5219 cells containing pSV55 or control M5219 cells. In addition, purified spinach RuBPCase was used as a control. All three samples in 50 ml of 50 mM Tris-HCl *p*H 8.0, 20 mM $MgCl_2$, 1 mM EDTA, 1 mM β-mercaptoethanol and 25 mM $NaHCO_3$ were incubated for 15 min at 30 °C. ^{14}C-CABP was added to a final concentration of 10 μM (ref. 3) and incubation continued for 1 h. NaCl was added to 0.1 M and the extracts passed through 1 × 5 cm columns of immobilized anti-wheat RuBPCase[14] equilibrated with the incubation buffer. The columns were washed with 50 mM Tris-HCl *p*H 8.0, 1 M NaCl, 20 mM $MgCl_2$, 1 mM EDTA, 1 mM β-mercaptoethanol, 0.1% Triton X-100 (25 ml), then with incubation buffer (50 ml). Immunoadsorbed protein was eluted with 8 M urea[14] and 0.5-ml fractions collected. Half of each fraction was counted using liquid scintillation counting, the remainder was precipitated with trichloroacetic acid, electrophoresed on a SDS/15% polyacrylamide gel, and probed by Western blotting.

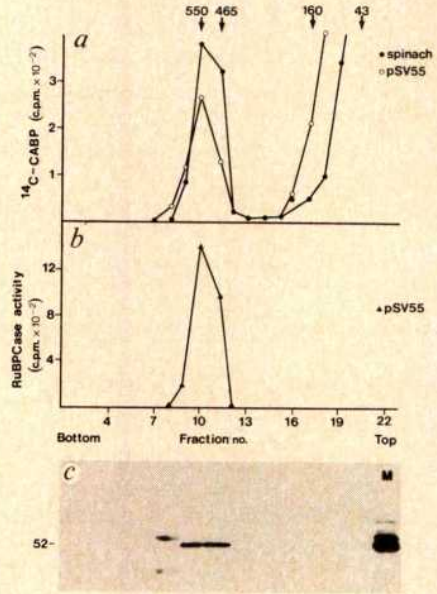

Fig. 4 Velocity sedimentation of RuBPCase in sucrose gradients. *a*, Gradient profile of ^{14}C-CABP-treated protein using spinach RuBPCase (●) or induced pSV55-containing cells (○). *b*, Distribution of RuBPCase activity on a sucrose gradient using induced pSV55-containing cells (▲). *c*, Western blot of the gradient fractions shown in panel *b*. The M track is a maize leaf extract used as a marker. M_r markers shown by arrows.

Methods. Soluble protein extracts were prepared as described in Fig. 2 from induced and uninduced M5219 cells containing pSV55. β-Galactosidase was added as a marker to these extracts and 500 μl was layered on to an 11-ml linear 7–25% sucrose gradient in 0.1 M Tris-HCl *p*H 8.0, 20 mM $MgCl_2$, 10 mM $NaHCO_3$, 1 mM EDTA, 1 mM mercaptoethanol. The gradients were centrifuged for 24 h at 25,000 r.p.m. and 4 °C in a Sorvall TST41 swinging bucket rotor. Fractions (0.5 ml) were collected from the bottom of the tube and assayed for RuBPCase activity[11]. Alternatively, the protein extract was incubated with ^{14}C-CABP at 10 μM concentration for 1 h before centrifuging. In this case, the gradient fractions were counted directly for ^{14}C content. Aliquots of fractions were also analysed by electrophoresis and Western blotting to locate the position of the L polypeptide on the gradient. All gradients had an internal marker, β-galactosidase (M_r 465,000), that could be assayed directly[24]. In addition, identical calibration gradients were centrifuged at the same time containing spinach RuBPCase (M_r 550,000), β-galactosidase (465,000), aldolase (160,000) and ovalbumin (43,000).

expressed by LS pairs present in the L_8S_n structures irrespective of the value of *n*. This system should provide an opportunity to gain further understanding of the assembly mechanisms and the importance of subunit contact sites in forming and maintaining the structure of the holoenzyme.

We thank E. Remaut, S. F. Delaney and J. Messing for strains and plasmids; R. B. Flavell, J. R. Evans, G. Voordouw, T. J. Andrews and G. H. Lorimer for helpful comments and advice, and C. Veeger for giving S.M.V. leave of absence for this work. Financial support was provided by the AFRC and the Agricultural University, Wageningen.

Note added in proof: By increasing the expression of S, we find that RuBPCase activity is also enhanced, suggesting that the S binding sites on the L octamer can be increasingly saturated by S overproduction.

Renal cytochrome P450-related arachidonate metabolite inhibits $(Na^+ + K^+)$ATPase

The function of the nephron, the anatomical unit of the kidney, is segmented; at least 12 segments have been identified that differ in their morphology, transport properties and hormonal responsiveness[1]. The medullary portion of the thick ascending limb of the loop of Henle (mTALH) has one of the highest concentrations of $(Na^+ + K^+)$ATPase found in mammalian tissues[2], reflecting the importance of this nephron segment in the regulation of extracellular fluid volume, as active sodium transport is driven by $(Na^+ + K^+)$ATPase[1]. Here, in cells derived primarily from the mTALH of the outer medulla of rabbit kidney, we have identified a cytochrome P450-dependent monooxygenase system[3] which metabolizes arachidonic acid to two biologically active oxygenated products; one of the products inhibits $(Na^+ + K^+)$ATPase and the other relaxes blood vessels. We report that formation of these oxygenated arachidonate metabolites is stimulated by arginine vasopressin (AVP) and salmon calcitonin (SCT).

Male New Zealand White rabbits (3.0-3.5 kg) were anaesthetized with sodium pentobarbital (30 mg per kg), and the inner stripe of the outer medulla excised, cut into small pieces and trypsinized for 20 min in trypsin-EDTA (1×) plus 0.1% bovine serum albumin. A single-cell suspension of outer medullary cells was prepared and separated into several fractions by centrifugal elutriation[3,4]. Cells derived mainly from the mTALH were eluted at a flow rate of 19 ml min^{-1} at 2,000 r.p.m., at 20 °C[3]. Over 90% of the cells were viable as determined by Trypan blue exclusion, electron microscopic appearance and metabolic activity. After cell separation, ~80% of the cells proved to be mTALH in origin, based on electron microscopic criteria and immunofluorescent localization of Tamm-Horsfall protein, a specific marker for mTALH cells[5]. The remainder were cells derived from proximal tubules and collecting ducts. The specific activity of alkaline phosphatase, a marker for proximal tubule cells[6], decreased threefold after separation of mTALH cells from outer medullary cells, in association with a fourfold increase in the ability of the separated mTALH cells to metabolize arachidonic acid to oxygenated metabolites.

Incubation of mTALH cells with ^{14}C-labelled arachidonic acid resulted in formation of oxygenated metabolites, identified as peaks I and II (see Fig. 1), which accounted for 30-40% of the recovered radioactivity. Formation of the arachidonate

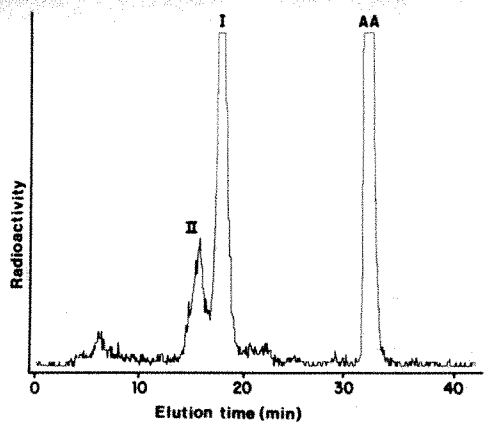

Fig. 1 Reverse-phase chromatography of arachidonic acid metabolites formed by mTALH cells. The retention times of peaks I and II were 18.2 and 15.7 min, respectively, while those for the monohydroxyeicosatetraenoic acids (mono-HETEs) in this HPLC separation were as follows: 15-HETE, 19 min; 11-HETE, 20 min; 12-HETE, 21 min; 9-HETE, 22 min; 5(*S*),12(*S*)-diHETE, 17.5 min.

Methods. Cells (3×10^6 ml^{-1}) were incubated in phosphate-buffered saline (PBS) with 0.4 μCi ^{14}C-arachidonic acid (7 μM; specific activity 56 mCi $mmol^{-1}$) at 37 °C for 30 min. The reaction was stopped by acidification to *p*H 4.0, the cells were removed by centrifugation and the media extracted with ethyl acetate. Arachidonic acid metabolites were separated by HPLC on a μ Bondapack C_{18} column, using a linear solvent gradient ranging from water:acetonitrile (1:1, containing 0.1% acetic acid) to 100% acetonitrile (containing 0.1% acetic acid); the rate of change was 1.25% per min at a flow rate of 1 ml min^{-1}. Radioactive products were detected using a radioactive flow detector. Fractions containing peaks I and II were collected separately, methylated with a freshly prepared solution of diazomethane in ether and subjected to further purification on normal-phase HPLC using a μ Porasil column and solvent system comprising hexane/isopropanol/acetic acid (98:2:0.1) at a flow rate of 1 ml min^{-1}. The purified methylated products were further derivatized to the trimethylsilyl derivatives and subjected to GC-MS analysis, using a Hewlett-Packard HP-5985A GC-MS system. The samples were separated on a glass column (1% SE-30). Operational conditions of the GC-MS were: injection port 250 °C; initial temperature of 180 °C increasing at a rate of 8 °C min^{-1} up to 250 °C; interface 275 °C; ion source 300 °C and electron impact energy of 70 eV. GC-MS analysis revealed that each peak separated by HPLC contained more than one compound. A major compound associated with peak II can be defined as the methyl ester-trimethylsilyl derivative of 11,12-dihydroxyeicosatrienoic acid because the fragments at $m/z = 496$ (M^+), 465 ($M^+ - 31$), 406 ($M^+ - 90$), 385 ($M^+ - 111$), 315 ($M^+ - 181$), 295 and 213 are characteristic of this structure. A major compound associated with peak I has prominent fragments at $m/z = 316$ ($M^+ - 18$), 303 ($M^+ - 31$), 233, 190 and 176, suggesting the presence of the methyl ester derivative of 5,6-epoxyeicosatrienoic acid.

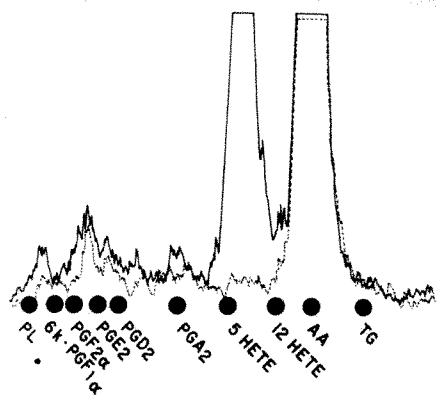

Fig. 2 Arachidonic acid metabolism by a broken cell preparation of mTALH cells. Cells were lysed by two cycles of freeze-thaw with liquid nitrogen in distilled water, then adjusted to PBS, *p*H 7.4. Broken cell preparations (200 μl, 80–100 μg protein) were incubated with ^{14}C-arachidonic acid (0.2 μCi) plus 'cold' arachidonic acid (10 μM) in the presence (—) and absence (- - -) of NADPH (1 mM) at 37 °C for 30 min. The reaction was stopped by acidification to *p*H 4.0 and extracted with ethyl acetate. The final extract was subjected to TLC for separation of arachidonic acid oxygenated metabolites using the upper phase of ethyl acetate/isooctane/acetic acid/water (110:50:20:100). PL, phospholipids; 6 k-$PGF_{1\alpha}$, 6-keto-prostaglandin $F_{1\alpha}$; PGE_2, PGD_2 and PGA_2, prostaglandin E_2, D_2 and A_2, respectively; TG, triglycerides; HETE, hydroxyeicosatetraenoic acid; AA, arachidonic acid. The radioactive peak appearing between the 5- and 12-HETE standards consists of peak I and peak II defined in Fig. 1. Formation of prostaglandins accounted for only 3–5% of the radioactivity recovered.

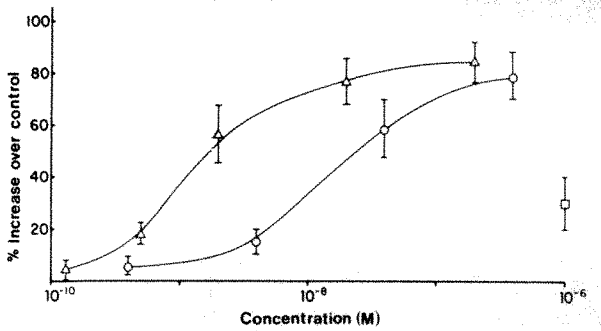

Fig. 3 Hormonal stimulation of arachidonic acid metabolism in mTALH cells prelabelled with ^{14}C-arachidonic acid (0.4 μCi per 3×10^6 cells) for 90 min at 37 °C. Within 90 min, 80–90% of ^{14}C-arachidonic acid was incorporated into phospholipids, chiefly phosphatidylcholine and phosphatidylethanolamine, and triglycerides. The cell suspension was centrifuged, then the cells were resuspended in fresh PBS and incubated for an additional 10 min with the following peptide hormones: AVP (○, 4×10^{-10}–4×10^{-7} M), SCT (△, 10^{-10}–2×10^{-7} M) and bradykinin (□, 10^{-6} M). The reaction was stopped by acidification, cells were removed by centrifugation and the media extracted with ethyl acetate. Arachidonic acid metabolites were separated by TLC as described in Fig. 2 legend; radioactive zones corresponding to peaks I and II were cut out and counted using a liquid scintillation counter. The per cent increase in the formation of peaks I and II compared with the unstimulated control value was plotted. The control value of 0.060 ± 0.007 μg per mg protein per 10 min is considerably lower than the values obtained when the 90-min period of prelabelling was omitted, as it represents release of bound radiolabelled arachidonic acid which was esterified to lipids during prelabelling. Values are mean ± s.e.m. of four experiments.

metabolites constituting peaks I and II was not affected by indomethacin[7] (3 μM), while eicosatetraynoic acid (30 μM), the acetylenic analogue of arachidonate[8], inhibited product formation by 80–90%. Separation by reverse-phase HPLC revealed that the arachidonate metabolites of peaks I and II had retention times different from those of arachidonate products of lipoxygenases, the mono- and dihydroxyeicosatetraenoic acids. Further, the lack of absorbance at 234 nm and 276 nm indicated the absence of a conjugated diene or triene structure, respectively, and suggested that the oxygenated metabolites of arachidonic acid were formed by a cytochrome P450-dependent system. At 50 μM, SKF-525A (β-diethylaminoethyldiphenylpropyl acetate hydrochloride), an inhibitor of cytochrome P450-dependent enzymes[9], reduced product formation by mTALH cells by more than 70% (from 2.52 ± 0.66 μg to 0.27 ± 0.06 μg of arachidonic acid converted per mg protein per 30 min), while induction of cytochrome P450 with 3-methylcholanthrene and β-naphthoflavone[10] (40 mg per kg per day on each of 3 days, injected intraperitoneally) increased arachidonic acid conversion to 4.17 ± 1.02 μg per mg protein per 30 min. In addition, product formation by cell-free homogenates of mTALH was dependent on the presence of NADPH (Fig. 2), suggesting that arachidonic acid metabolism in mTALH cells occurs via an NADPH-dependent cytochrome P450-linked monooxygenase pathway[11]. In view of studies based on immunofluorescent[12] and microanalytical[13] methods that have assigned the cytochrome P450-monooxygenase system to the proximal tubules, the present study, which has localized this pathway of arachidonate metabolism also in the mTALH, should be interpreted with caution.

Segmentation of nephron responsiveness to hormones may be expressed through adenylate cyclase-sensitive receptors[14]. AVP-dependent adenylate cyclase activity is restricted to the collecting ducts and mTALH[15]. Calcitonin also stimulates adenylate cyclase in the mTALH whereas adrenocorticotropic hormone, parathyroid hormone and isoprenaline do not[14]. AVP and SCT, when added to mTALH cells in concentrations ranging from 10^{-10}–10^{-7} M, stimulated release of the oxygenated arachidonate metabolites of peaks I and II by as much as twofold, depending on the dose of the peptides (Fig. 3). In contrast, concentrations of bradykinin and angiotensin II that were three orders of magnitude greater, had lesser effects on the release of oxygenated metabolites of arachidonic acid than either AVP or SCT. The phosphodiesterase inhibitor, 1-isobutyl-3-methylxanthine (10 μM), increased formation of peaks I and II almost twofold, as did dibutyryl cyclic AMP (1 mM). Parathyroid hormone and isoprenaline, which do not affect adenylate cyclase in the mTALH segment[12], had no effect on arachidonic acid metabolite formation by mTALH cells at concentrations of 10^{-10}–10^{-7} M.

Peak II proved to be a potent inhibitor of $(Na^+ + K^+)$ATPase whereas peak I was a weak inhibitor (Table 1). Peak I but not peak II relaxed rabbit pulmonary artery rings that had been precontracted with phenylephrine (5×10^{-7} M); peak I (4×10^{-8}–2.3×10^{-7} M, $n=4$) resulted in a 40–60% relaxation whereas higher doses of peak II (2.9×10^{-7}–1.2×10^{-6} M, $n=3$) had no detectable effects. Acetylcholine, used as a standard, caused a 36% relaxation of vascular rings at a dose of 5×10^{-8} M. Gas chromatography–mass spectrometry (GC–MS) analysis of peaks I and II revealed major components consistent with the structures of the 5,6-epoxide and the 11,12-diol derivatives of arachidonic acid, respectively (see Fig. 1 legend).

The results of our study indicate that renomedullary cells respond selectively to hormonal stimuli by generating arachidonic acid metabolites via a cytochrome P450-dependent mechanism, and that one of these products inhibits $(Na^+ + K^+)$ATPase. A hormone-inducible modulator of $(Na^+ + K^+)$ATPase activity has long been sought[16] and has important consequences for the regulation of extracellular fluid volume and composition. These findings also have a bearing on selective activation of the nephron by hormones via stimulation of adenylate cyclase-sensitive segments such as those of the cortical collecting ducts and mTALH by AVP[14]. Moreover, the concentrations of AVP[15] and SCT[14] that stimulate adenylate cyclase activity in mTALH correspond to concentrations of these peptides which we have shown to increase formation of arachidonic

acid metabolites in this segment, that is, 10^{-10}-10^{-8} M. As the effects of SCT and AVP on arachidonic acid metabolism are mimicked by dibutyryl cyclic AMP, the natriuretic effects of SCT[17] and AVP[18] may be mediated by adenylate cyclase-induced arachidonic acid metabolism. A natriuretic effect of AVP which is localized to mTALH[18] has been dissociated from its effect on reabsorption of water[19]. Finally, a factor which diminishes the activity of $(Na^+ + K^+)$ATPase in the mTALH has been postulated by Postnov *et al.*[20] to account for the exaggerated natriuresis in response to volume expansion in clinical and experimental hypertension. In this regard, we have demonstrated more than a twofold increase in formation of cytochrome P450-related products of arachidonic acid metabolism by TALH cells in rabbits made hypertensive by constriction of the abdominal aorta[21]. In conclusion, the cytochrome P450-dependent pathway of arachidonate metabolism in mTALH could act as a common mechanism mediating natriuresis in response to hormones as well as to a natriuretic substance(s)[22] including circulating inhibitors of $(Na^+ + K^+)$ATPase activity, levels of which are thought to be elevated in hypertension[23].

We thank Dr R. William Caldwell for his help, Dr John R. Vane and Dr Patrick Y.-K. Wong for valuable discussions, and Mrs S. B. McGiff, Donna Centi, Pat Scholl and Shirley Klein for preparing the manuscript. This work was supported by USPHS grants HL 25394 and HL 25406 and by funds granted by the Charles H. Revson Foundation to New York Medical College. M.S. was a Fogarty International Fellow.

Received 2 October 1984; accepted 22 January 1985.

Table 1 Effect on $(Na^+ + K^+)$ATPase of arachidonic acid metabolites formed by renomedullary cells, primarily from the thick ascending limb of rabbit kidney

	Concentration* (μM)	% Inhibition of $(Na^+ + K^+)$ATPase†
Peak I	0.05	No effect
	0.28	10
	2.60	35
Peak II	0.06	34
	0.20	65
	0.66	70

ATPase inhibition was assayed using a microsomal preparation from canine heart, prepared and treated with 6 M sodium iodide, followed by 1.5 M deoxycholate-citrate. The final pellet was dialysed overnight at 4 °C against imidazole-EDTA (25 mM-1 mM) and stored at −50 °C according to the method of Pitts and Schwartz[24]. This enzyme was 98% ouabain (1 mM)-inhibitable, with an activity of 231 μmol inorganic phosphate per mg protein per h. The 50% inhibitory concentration of ouabain for this enzyme preparation was 0.5 μM. The effects of peaks I and II on $(Na^+ + K^+)$ATPase activity, in the presence and absence of 1 mM ouabain, were measured according to the method of Martin and Doty[25]. Inorganic phosphate was measured spectrometrically by the direct addition of stannous chloride solution to an aliquot of the extract which had been diluted with ethyl alcohol-sulphuric acid solution. For the $(Na^+ + K^+)$ATPase assay, 15 μg of enzyme was incubated for 30 min at 37 °C in 1 ml of a reaction mixture containing 50 mM Tris buffer, 5 mM MgCl, 100 mM NaCl, 10 mM KCl and 0.5 mM EDTA. The reaction was started by adding ATP (5 mM) and stopped by adding 10% trichloroacetic acid. Peaks I and II (Fig. 1) are the pooled fractions (separated by reverse-phase HPLC) of oxygenated arachidonic acid metabolites formed by mTALH cells obtained from three rabbits. An identical volume of the HPLC effluent similarly extracted did not inhibit $(Na^+ + K^+)$ATPase.

* The concentrations of peaks I and II were calculated from per cent conversion of ^{14}C-arachidonic acid (after correction for extraction efficiency) to these metabolites assuming a molar ratio of 1 : 1 for each; that is, mole of arachidonic acid converts to either mole of peak I or peak II. The concentrations were estimated on the basis of a relative molecular mass of 350 for oxygenated metabolites of arachidonic acid. The estimated amount of arachidonic acid products (peaks I and II) produced by 3×10^6 cells ml^{-1} was ~400 ng in 30 min of incubation. Thus, the approximate concentration of the arachidonate metabolite(s) in the incubate was 0.1 μM, a biologically effective concentration as judged by the inhibition of $(Na^+ + K^+)$ATPase.

† Inhibition of ouabain-sensitive $(Na^+ + K^+)$ATPase. Each value is the mean of duplicate determinations of $(Na^+ + K^+)$ATPase inhibitory activity of arachidonic acid products contained in peaks I and II. Student's paired *t*-test indicated a significant difference between the activity in the two peaks ($t = 6.03$, d.f. = 2, $P < 0.05$).

Calcium content of mitochondria and endoplasmic reticulum in liver frozen rapidly *in vivo*

A. P. Somlyo, Meredith Bond & Avril V. Somlyo

Pennsylvania Muscle Institute, The School of Medicine, B42 Anatomy-Chemistry Bldg/G3, University of Pennsylvania, Philadelphia, Pennsylvania 19104, USA

The recognition that the endoplasmic reticulum (ER), rather than the mitochondria, is the main organelle regulating the cytoplasmic Ca^{2+} concentration in non-muscle cells[1,2] supports the notion that an alternative physiological role of mitochondrial Ca transport[3–5] is the modulation of Ca-sensitive mitochondrial enzymes through small (micromolar) fluctuations in the concentration of mitochondrial matrix Ca^{2+} (refs 1, 5–7). The latter mechanism could operate only if the mitochondrial Ca concentration were low, as it is in muscle and retinal rods[8,9], below the levels saturating the regulated enzymes[5]. In contrast, if the ER serves as an intracellular Ca store, its Ca content would be expected to be high. In view of the major metabolic function of the liver, the question of whether hepatic mitochondrial matrix Ca^{2+} regulates metabolism is particularly important, but the range of Ca concentrations reported for isolated liver mitochondria is too wide[10–12] to provide a conclusive answer. Therefore, we have used electron probe X-ray microanalysis (EPMA) to measure the subcellular distribution of Ca in liver snap-frozen *in vivo*, and report here that the endoplasmic reticulum is a major intracellular store of Ca, while the concentration of Ca in mitochondria is low and compatible with the regulation of mitochondrial enzymes.

Figure 1 shows an electron micrograph of an unstained cryosection of rat liver used for electron probe analysis; there is minimal ice-crystal damage, allowing the identification of cell types and intracellular organelles. The Ca concentration in red blood cells within hepatic sinusoids in the same sections used for parenchymal cell measurements, 0.1 ± 0.2 mmol per kg dry wt(± s.e.m.; $n = 34$), is consistent with the micromolar total Ca content of red blood cells[13] and provides an internal estimate

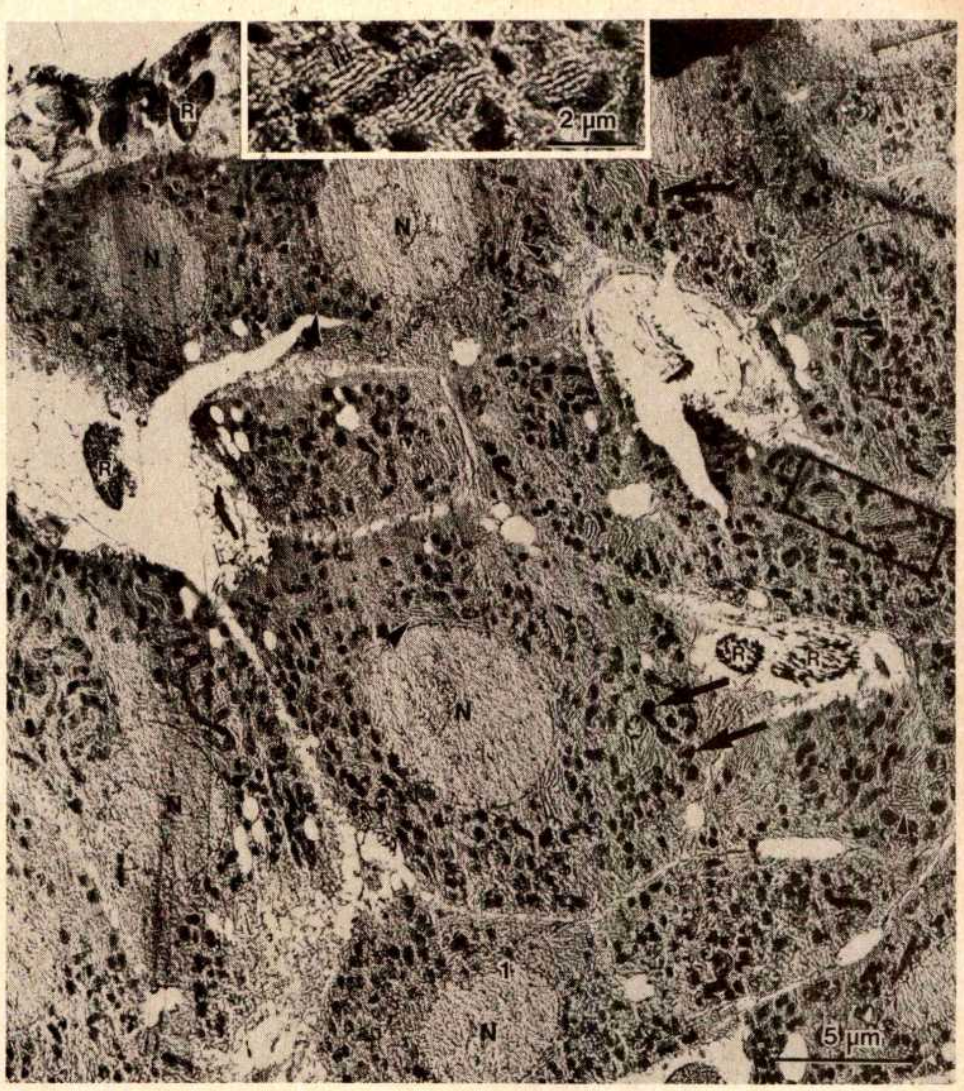

Fig. 1 Electron micrograph of an ultrathin, freeze-dried cryosection obtained from rat liver rapidly clamp-frozen *in situ* with frozen Freon 22. Nuclei (N) and numerous mitochondria (arrows) are indicated, as well as stacks of rough ER (arrowheads). The boxed region is enlarged (inset) to show the stacks of rough ER; some regions show periodic bumps (small arrows) along the membrane which are thought to be ribosomes. The EPMA measurements of the Ca content of ER were obtained from such stacked tubules. Red blood cells (R) are also evident in the liver sinusoids.

Methods. Rats were anaesthetized intraperitoneally with Nembutal (50 mg per kg), an incision made in the abdominal wall over the liver and the rat placed on its abdomen in a cloth hammock above an environmental chamber maintained at 37 °C with high humidity. The liver was exposed gently, without touching its surface, through a slit in the cloth hammock and suspended in the atmosphere of the environmental chamber. The freezing clamp with two opposing aluminium cups filled with solidified Freon 22 was removed from the nitrogen and when the surface of the solid Freon had melted, the door of the environmental chamber was opened and the lobe of the liver clamped rapidly. The temperature of the melted Freon surface is at the melting point of Freon 22 and moulds to the irregular tissue surface, promoting a good contact between the coolant and the tissue. The concept of using melting Freon 'popsicles' originated with Morris Karnovsky (unpublished). The liver was sectioned at −130°C in a cryo-ultramicrotome, then freeze-dried[32].

of the very small errors of the EPMA measurements. The low Ca content of mitochondria and the significantly higher Ca concentration in the ER are shown clearly in the averaged X-ray spectra in Fig. 2. The concentrations of K, Na, Cl, Mg, P and S, measured in the same regions, are given in Table 1. Estimates of the K concentration in fresh liver obtained by other methods are comparable[14].

The mitochondrial calcium concentration was 0.8 ± 0.1 (±s.e.m.) mmol per kg mitochondria ($n = 97$; 29 cells, four rats: two fasted, two fed), which is equivalent to ~1.1 nmol per mg mitochondrial protein (ratio of protein to dry mass = 70%). The ratio of free matrix Ca^{2+} to total mitochondrial Ca, in mitochondria isolated from liver, has been estimated as 7×10^{-4} (ref. 15). Given this value, we can estimate that (for 64% mitochondrial H_2O) the free Ca^{2+} concentration in the mitochondrial matrix of rat liver is ~0.3 μM (95% confidence limit 0.2–0.4 μM), well within the range (0–2 μM) in which mitochondrial dehydrogenases are regulated. If the mitochondrial Ca concentration

Table 1 Subcellular distribution of calcium and other elements in rat liver parenchymal cells (four animals) (mmol per kg dry wt)

	No. of spectra	Na	Mg	P	S	Cl	K	Ca	% Cell volume*	% Total cell Ca
Mitochondria	97	54 ± 3	43 ± 1	360 ± 7	316 ± 4	75 ± 3	314 ± 5	0.8 ± 0.1	20	5
Rough endoplasmic reticulum	24	80 ± 8	76 ± 2	920 ± 21	224 ± 8	94 ± 5	579 ± 17	5.0 ± 0.4	9.4	14–23†
Nuclei	21	77 ± 6	53 ± 2	557 ± 16	245 ± 8	117 ± 6	625 ± 22	0.8 ± 0.4	6	1
Other regions‡	29	75 ± 6	53 ± 2	653 ± 20	241 ± 9	103 ± 5	465 ± 15	4.0 ± 0.4		
Total cell	20	53 ± 4	46 ± 2	564 ± 12	230 ± 9	106 ± 4	479 ± 20	3.4 ± 0.4		

The instrumentation and methods used for EPMA, including calibration, have been published elsewhere[31–34]. To obtain the precision required for these measurements, individual spectra were collected for 400–600 s, until the measurement error of a single spectrum was 1.1 mmol Ca per kg dry wt. Spectra were collected from mitochondria with 75–100-nm diameter probes; from ER with 100-nm or 1,000-nm diameter probes over stacks of ER tubules that included the intervening cytoplasm and, therefore, give an underestimate of the Ca concentration in the ER; from nuclei using probes of diameter 3–10 μm and for total cell measurements, using defocused probes covering whole cell profiles. Values are the mean ± s.e.m.

* From refs 23, 24.

† The lower value is based on the Ca concentration ([Ca]) of the stacks of rough ER, the higher value on the [Ca] measured with 10–20-nm diameter probes over the ER lumen (see text).

‡ Regions in the cell exclusive of nuclei, mitochondria and stacks of rough ER, which, based on known liver structure, would include the smooth ER tubules that were not imaged in the cryosections.

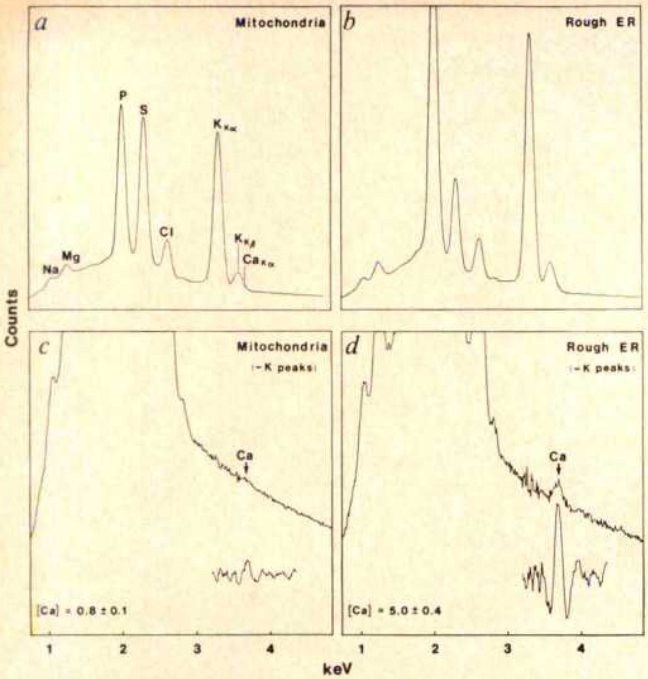

Fig. 2 Averaged X-ray spectra of mitochondria (*a*, *c*) and rough ER (*b*, *d*). The Cu background was subtracted from all spectra by the computer. Peaks representing other elements are indicated. In *c* and *d* (8 × higher gain), the potassium K_α and K_β peaks have also been removed to allow a comparison of the relative sizes of the Ca peaks of mitochondria and ER. The insets show the Ca peaks in the filtered spectra.

were much higher (that is, a total mitochondrial Ca content significantly greater than 2–3 mmol per kg dry wt), the Ca^{2+} regulatory sites on the enzymes would be saturated with Ca^{2+}. Conversely, the mitochondrial Ca content measured by us is insufficient for significant activation of the mitochondrial efflux pathway (apparent $K_m = 9.7\ \mu M$ in isolated liver mitochondria[15]), as would be required for effective mitochondrial regulation of cytoplasmic Ca^{2+} (ref. 5). The reported Ca concentrations of isolated liver mitochondria cover a wide range, depending on the isolation conditions (for review, see ref. 5), with recent values between ~2 and 17 nmol per mg protein[10,12,16]. The lowest values have been found in mitochondria isolated in Ca-free media[10,16], but we note that in smooth muscle[9], incubation in Ca-free solutions reduces the mitochondrial Ca content, measured *in situ*, from 1.6 to 0.1 mmol per kg dry weight.

Our findings also have some implications for the reported release of mitochondrial Ca by agents such as phenylephrine, adrenaline or vasopressin[17]. The Ca content of mitochondria isolated from phenylephrine-treated, isolated hepatocytes in the latter study was higher (5.0 nmol per mg protein) than we found in the untreated animals *in situ*. Therefore, phenylephrine and similar agents, instead of having an *in vivo* effect on mitochondrial Ca, may merely reduce the translocation of Ca into mitochondria during isolation[10], possibly through the depletion of other sources of intracellular Ca, such as the endoplasmic reticulum.

The concentration of Ca in regions of the endoplasmic reticulum was 5.0 ± 0.4 mmol per kg dry wt; this is very much higher than the concentration in mitochondria or in nuclei (Table 1) but may still be an underestimate, as the electron probe diameters were larger than the diameters of the ER tubules (Fig. 1) in the cryosections. The close-packing of the stacks of tubules of rough ER (Figs 1, 3) over which our measurements were made, suggests that the Ca concentration may have been underestimated by a factor of 2, and that the true Ca content of the rough ER is perhaps 8–10 mmol per kg dry weight. This value is still much higher than the Ca content (~2 nmol per mg protein) of microsomes isolated from liver[11], but is comparable to the steady-state Ca content of 10 nmol Ca per mg protein

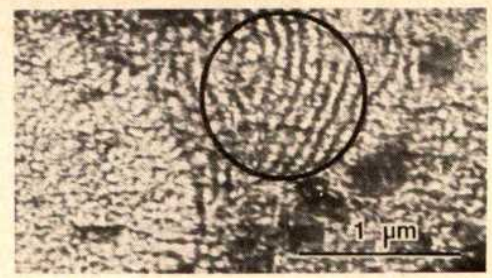

Fig. 3 High-magnification view of a portion of a parenchymal liver cell in an ultrathin cryosection, showing a stacked array of rough endoplasmic reticulum. The encircled region indicates the area that was irradiated with the electron beam during electron probe microanalysis, and which contained the following concentrations (± s.d.) of calcium, magnesium and phosphorus: 4.2 ± 0.5, 87.0 ± 1.5 and 995 ± 4.6 mmol per kg dry wt, respectively.

in microsomes equilibrated with 70 nM free Ca^{2+} (ref. 18).

The high phosphorus (920 ± 21 mmol per kg dry wt) and magnesium (76.1 ± 1.9 mmol per kg dry wt) concentrations in the stacks of rough ER reflect the presence of membrane phospholipids and ribosomes. When probes from a field emission gun were focused (8–20 nm diameter) on ribosomes attached to the stacked ER, the P and Mg contents measured (respectively, 1,129 ± 77 and 89.9 ± 3.5 mmol per kg dry wt, $n = 4$) were even higher, confirming that ribosomes[19,20] make a large contribution to the high P and Mg concentrations in the stacked rough ER. The Ca concentration in the ribosomes was 0.1 ± 0.6 mmol per kg dry wt, and in the lumen of ER tubules (measured with similar small (8–20-nm) probes) it was 8.2 ± 1.9 mmol per kg dry wt ($n = 4$), consistent with the estimate based on measurements made with defocused probes over stacks of rough ER.

The 'cytoplasmic' regions (labelled 'other' in Table 1) that excluded visible organelles (mitochondria, nuclei, stacks of rough ER) had a relatively high Ca content but, based on known liver morphology, they probably also included tubules of smooth and/or rough ER not imaged in unstained cryosections. Therefore, some of the Ca measured in these cytoplasmic regions may be present in the lumen of non-visualized ER, as well as bound to cytoplasmic and membranous proteins such as calmodulin, calelectrin, etc.[21,22]. The Ca content of nuclei was 0.8 ± 0.4 mmol Ca per mg protein ($n = 21$), providing an upper limit for the Ca that could be bound to small, diffusible cytoplasmic proteins capable of passing through nuclear pores. We were unable to determine the Ca content of individual tubules of smooth ER that were not visualized in the unstained cryosections. EPMA measures total (free and bound) Ca, and our measurements are not directly comparable with values of free and exchangeable Ca measured using other methods.

We determined the subcellular distribution of total liver cell Ca by combining our results with stereological measurements[23,24] of the fractional volume occupied by various organelles (Table 1); the Ca content of the mitochondria (20% of the cell volume) and of the nucleus (6% of the cell volume) accounts for only ~5% and 1%, respectively, of the 3.4 mmol per kg dry wt total cell Ca. The Ca content of whole fresh rat liver, including extracellular Ca, is reported to be 4.1 mmol per kg dry wt[5]. The minimal fraction of cell Ca in the rough ER, based on a 9.4% volume and on the Ca measurements obtained with defocused probes over the stacks of rough ER, is 14%; this value increases to 23% if the Ca content of the lumen of the rough ER is included. Considering the total cell volume of the ER (15% = 9.4% rough ER and 5.9% smooth ER) and assuming that the Ca concentration in the smooth ER is the same as that in the rough ER, the fraction of the total cell Ca present in the ER could be 23–27%.

Thus, our results support the view[1,6,7,26] that mitochondrial enzymes may be regulated by matrix free Ca^{2+}, and extend it to a metabolically active, intact, blood-perfused organ. The mitochondrial Ca content is far below the concentration[5] at

which the mitochondrial Ca efflux pathway is active and mitochondria could effectively regulate cytoplasmic free Ca^{2+}. The high Ca content of the ER is consistent with the view that this is the source of Ca released by inositol trisphosphate[27-30] and other agents. Our results also show that it is possible to freeze some cells in a near physiological condition *in vivo*, and make direct measurements with EPMA of the composition of organelles at high spatial resolution and sensitivity[31,32].

This work was supported by grant HL15835 to the Pennsylvania Muscle Institute and by the University of Pennsylvania Diabetes Center to M.B. We thank Mr John Silcox for his expertise in cryo-ultramicrotomy.

Identification of the human analogue of a regulator that induces differentiation in murine leukaemic cells

Nicos A. Nicola, Colin G. Begley & Donald Metcalf

Cancer Research Unit, Walter and Eliza Hall Institute of Medical Research, PO Royal Melbourne Hospital, Parkville, Victoria 3050, Australia

We have recently purified murine granulocyte colony-stimulating factor (G-CSF)[1], a regulatory glycoprotein which stimulates granulocyte colony formation from committed murine precursor cells in semi-solid agar cultures[2]. G-CSF is one of a family of colony-stimulating factors that regulate the growth and differentiation of granulocytes and macrophages[3-5]. While the other murine CSFs (granulocyte–macrophage (GM)-CSF, macrophage (M)-CSF and multi-CSF) show little or no differentiation-inducing activity on murine myelomonocytic leukaemia cell lines, G-CSF (or MGI-2[6]) is able to induce the production of terminally differentiated cells from WEHI-3B and other myeloid leukaemia cell lines[6-8]. More importantly, G-CSF-containing materials suppress the self-renewal of myeloid leukaemia stem cells *in vitro*[8] and the leukaemogenicity of treated myeloid leukaemic cells *in vivo*[9-13]. It is important to identify the human analogue of murine G-CSF so that its effectiveness on human myeloid leukaemia cells can be assessed. Here we show that an analogue of G-CSF does exist among the CSFs produced by human cells and that the murine and human molecules show almost complete biological and receptor-binding cross-reactivities to normal and leukaemic murine or human cells. The human G-CSF analogue is identified as a species of CSF that we have previously described as CSF-β (ref. 14).

Two CSFs in human placental conditioned medium that are active on human granulocyte and macrophage progenitor cells have been separated on the basis of differences in hydrophobicity[14]; the earlier-eluting species (CSF-α) stimulated the formation of neutrophilic granulocyte, macrophage and eosinophilic granulocyte colonies with colony formation peaking by day 14 of culture, while the later-eluting species (CSF-β) stimulated almost exclusively the formation of neutrophilic granulocyte colonies peaking by day 5-7 of culture. We have confirmed the existence of these two species of human CSF by using medium conditioned by the human bladder cell line 5637 (Fig. 1), as have others using medium conditioned by the GCT cell line[15]. After fractionation on phenyl-Sepharose (Fig. 1), CSF-β fractions which were active on human bone marrow cells also stimulated granulocyte colony formation by murine marrow cells and induced differentiation in murine myelomonocytic leukaemia WEHI-3B D^+ cells, whereas CSF-α fractions had no such effects. The low frequency, small size and maturity of the murine granulocytic colonies stimulated by CSF-β were typical of colonies stimulated by G-CSF[2].

In agar cultures of human bone marrow cells, pure G-CSF stimulated granulocytic colony and cluster formation comparable in number, size and rate of development to those stimulated by CSF-β. To minimize possible indirect effects of CSF-producing cells in unfractionated human marrow cultures, we compared the activities of G-CSF and CSF-β in cultures of human marrow cell fractions highly enriched for promyelocytes and myelocytes by fluorescence-activated cell sorting (FACS)[16]. The dose-response curves for proliferation in cultures of these cells stimulated by partially purified CSF-α, CSF-β and pure G-CSF were almost identical in shape and, in particular, CSF-β and G-CSF stimulated the development of equal numbers of clones (Fig. 2*a*). CSF-β and G-CSF also showed similar dose-response curves for inducing differentiation in WEHI-3B D^+ colonies, while CSF-α was inactive in this assay (Fig. 2*b*). Interestingly, the dose-response curves for inducing differentiation of WEHI-3B D^+ colonies were shifted eightfold to the left for both CSF-β and G-CSF compared with the dose-response curves for human progenitor cells (note the different dilutions used in Fig. 2*a*, *b*).

^{125}I-labelled G-CSF demonstrates specific, saturable binding to WEHI-3B D^+ leukaemic cells and normal murine bone marrow cells[17]. ^{125}I-G-CSF also bound specifically to normal human bone marrow and blood cells as well as a variety of fresh human myeloid leukaemic cells (Table 1). The binding of ^{125}I-G-CSF to human leukaemias paralleled its specificity of action on normal target cells. Cells from all acute myeloblastic leukaemias, chronic myeloid leukaemias, acute promyelocytic leukaemias and pre-leukaemias showed higher levels of binding than those observed for lymphocytic leukaemia cells. Acute myelomonocytic leukaemias showed relatively little binding of ^{125}I-G-CSF compared with the granulocytic leukaemias; this granulocytic specificity of the binding exhibited by ^{125}I-G-CSF was confirmed by autoradiography of human bone marrow cells (Fig. 3) which showed that cells of the granulocytic cell lineages were specifically labelled (promyelocytes more intensely labelled than polymorphs) while lymphoid and erythroid cells were not. For comparison, Fig. 3 shows specific labelling of acute promyelocytic leukaemic blast cells.

The binding of ^{125}I-G-CSF to WEHI-38 D^+ cells is inhibited in a dose-dependent manner by unlabelled G-CSF but not by

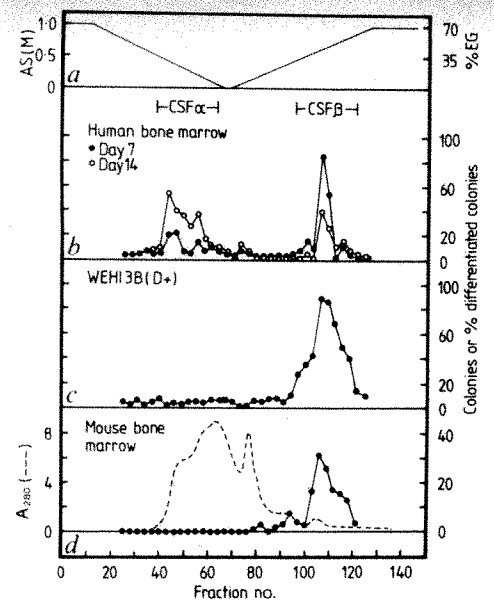

Fig. 1 Separation of human bladder cell line (5637) conditioned medium on phenyl-Sepharose CL-4B. The bladder cell line[21,22] was incubated at 1×10^6 cells ml^{-1} in DMEM containing 5% FCS at 37 °C in 10% CO_2 in air for 7 days. The conditioned medium was centrifuged at 10,000*g* for 30 min, made 1 M in ammonium sulphate and applied to a column of phenyl-Sepharose CL-4B (2.6 × 40 cm) equilibrated in 1 M ammonium sulphate/0.1 M sodium phosphate buffer *p*H 6.0 containing Tween 20 (0.02%) and sodium azide (0.02%) (start buffer). The column was eluted with a 200-ml linear gradient from start buffer to distilled water, followed by a 200-ml linear gradient from distilled water to 70% ethylene glycol (*a*) at a flow rate of 20 ml h^{-1}, and 3.5-ml fractions were collected. The fractions were exchanged into phosphate-buffered (20 mM, *p*H 7.4) saline (0.15 M) containing Tween 20 (0.02%) by passage through Sephadex G-25M and sterilized by passage through Millipore 0.45-μm filters. Aliquots of each fraction were then assayed for their ability to stimulate colony formation of normal bone marrow cells from human rib (100,000 cells per plate), colonies being scored on days 7 and 14 of culture (*b*); their ability to induce differentiation in colonies formed by murine myelomonocytic leukaemia cells (WEHI-3B D^+) (300 cells per plate, ~180 colonies) after 7 days of culture (*c*); and their ability to induce colony formation by normal murine C57BL/6 bone marrow cells (75,000 cells per plate) after 7 days of culture (*d*). In all cases cultures were prepared in 35-mm Petri dishes containing 0.3% agar, DMEM and 20% FCS and 10% by volume of fraction to be assayed, and were incubated at 37 °C in 10% CO_2 in air in a fully humidified incubator. Colonies comprising >50 cells were scored at ×35 magnification under a dissecting microscope and differentiated WEHI-3B D^+ colonies were enumerated by their characteristic dispersed morphology. The absorbance of the fractions at 280 nm (dashed line) is also shown in *d*. AS, ammonium sulphate concentration; % EG, percentage by volume of ethylene glycol in water.

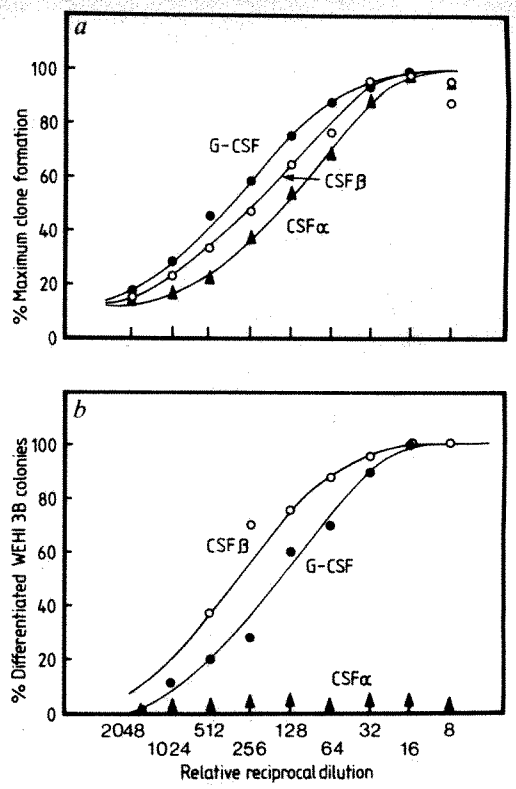

Fig. 2 Ability of human and murine colony-stimulating factors (CSFs) to stimulate clonal proliferation by human cells (*a*) or to induce differentiation in a murine leukaemic cell line (*b*). Human CSF-α and CSF-β preparations were from bladder cell line-conditioned medium separated by phenyl-Sepharose CL-4B chromatography (pooled as shown in Fig. 1), and murine G-CSF was pure material from mouse lung-conditioned medium, purified as described elsewhere[1]. The human promyelocyte-rich cell fraction (*a*) was obtained from normal human bone marrow cells after fractionation by FACS using a monoclonal antibody raised against human neutrophils as described elsewhere[16]. This fraction contained 35% promyelocytes and myelocytes with no other cells capable of proliferation. Each CSF was titrated in serial twofold dilutions for its ability to stimulate total clone formation (>2 cells) in agar cultures of 2,000 enriched cells as described in Fig. 1 legend, except that clones were scored on day 5 of culture. Maximum clone numbers were 175 for CSF-β or G-CSF and 150 for CSF-α. The distribution of clone sizes was almost identical for CSF-β and G-CSF (2–21 cells) and clones were larger than for CSF-α (2–9 cells). The same pools of CSFs were assayed for their ability to induce a differentiated morphology in murine WEHI-3B D^+ colonies after 7 days of culture (*b*). Note that the dilutions of samples in *b* were eightfold diluted relative to the dilution of samples in *a* in order to compare more easily the span of the titration curves in the two assay systems.

M-CSF, GM-CSF, multi-CSF or any of several unrelated growth factors[17]. Figure 4*c* shows that human CSF-β inhibited ^{125}I-G-CSF binding to WEHI-3B D^+ cells to the same extent as unlabelled G-CSF and that the dose-response relationship was indistinguishable from that for G-CSF when the data were standardized to the number of units added, based on the human colony-forming assay of Fig. 2. In contrast, human CSF-α and murine GM-CSF showed no inhibition of binding over the same dose range. Marrow cells of light density from patients with untreated chronic myeloid leukaemia or untreated acute myeloid leukaemia (with >90% leukaemic blast cells) gave binding data that were almost identical to those seen for murine WEHI-3B D^+ cells (Fig. 4*a*, *b*). Moreover, the dose-response relationships for inhibition of ^{125}I-G-CSF binding by unlabelled G-CSF or CSF-β were identical and occurred over the same concentration range as the inhibition of binding to WEHI-3B D^+ cells while, again, CSF-α and GM-CSF did not inhibit binding. Figure 4*d* shows that the binding of ^{125}I-G-CSF to BALB/c bone marrow cells was competed for equally by unlabelled G-CSF and CSF-β and that CSF-α, like GM-CSF, could inhibit only 30% of the specific binding sites; the latter effect appears to result from down-regulation of G-CSF receptors rather than receptor cross-reactivity (N.A.N. and D.M., unpublished).

Saturation binding and Scatchard analyses were performed for the binding of ^{125}I-G-CSF to human acute myeloid leukaemic bone marrow cells (>95% leukaemic blast cells) and murine leukaemic WEHI-3B D^+ cells (Fig. 5). Because we have noted previously[17] that Scatchard analysis of binding data for WEHI-3B D^+ cells becomes nonlinear at low levels of bound ^{125}I-G-CSF, the dissociation constants were determined from the limiting slopes of the Scatchard curves; these gave a dissociation constant of 102 pmol for binding to WEHI-3B D^+ cells and 98 pmol for binding to the acute myeloid leukaemic blast cells. The number of binding sites per cell, estimated from the intercepts on the abscissa, were 300 and 480 for WEHI-3B D^+ and human acute myeloid leukaemic cells, respectively.

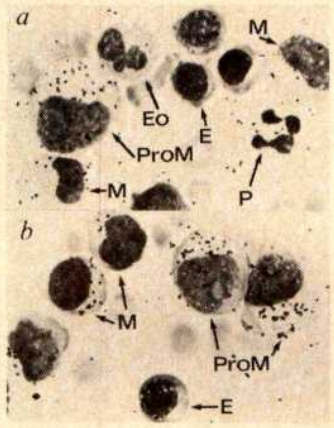

Fig. 3 Autoradiographs of the binding of ^{125}I-G-CSF to: *a*, normal human marrow; and *b*, acute promyelocytic leukaemic marrow. In *a*, note the heavily labelled promyelocyte (ProM) and labelled myelocytes (M) and polymorph (P) but unlabelled eosinophil (Eo) and erythroid cell (E). In *b*, note the labelled promyelocytes and myelocytes but unlabelled erythroid cell. Exposure time 1 month.

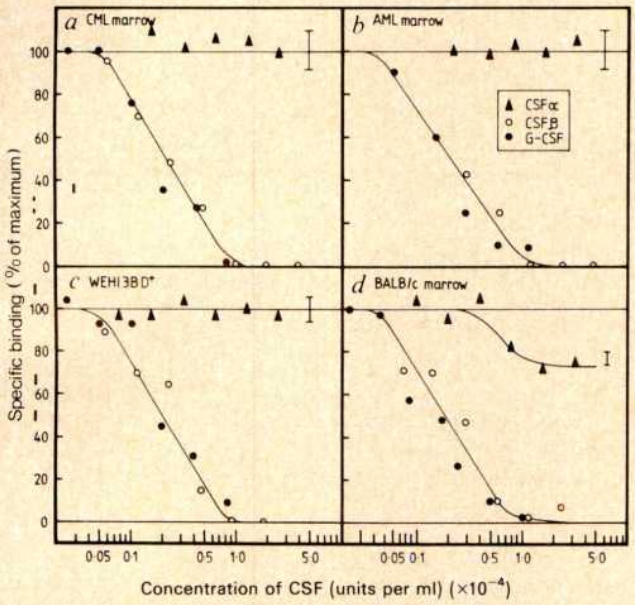

Fig. 4 Ability of human and murine colony-stimulating factors to compete for the binding of murine G-CSF to human and murine cells. Human CSF-α and CSF-β pools and murine G-CSF were obtained as described in Fig. 2 legend and units (U) standardized in the assay on human promyelocyte-enriched cells, as described in Fig. 2 legend (50 U being that amount giving 50% of a maximal clone response). ○, Unlabelled CSF-β; ●, unlabelled G-CSF; and ▲, unlabelled CSF-α. Iodinated G-CSF (prepared as described elsewhere[17] (80,000–200,000 c.p.m., specific activity 150,000–300,000 c.p.m. ng^{-1}) and increasing amounts of unlabelled G-CSF, CSF-α or CSF-β as shown were added to 5×10^6 human chronic myeloid leukaemia (CML) bone marrow cells (density <1.077 g cm^{-3}) (*a*), 5×10^6 human acute myeloid leukaemia (AML) bone marrow cells (density <1.077 g cm^{-3}) (*b*), 2×10^6 WEHI-3B D$^+$ cells (*c*) or 5×10^6 BALB/c murine bone marrow cells (*d*) in DMEM/10% FCS (90 μl final volume) and incubated at 37 °C in 10% CO_2 in air for 1 h. Cells were then centrifuged (300*g*, 5 min) through 200 μl ice-cold FCS, the cell pellet was collected by cutting off the end of the tube, and this was counted in a γ-counter at 76% efficiency. Maximum (100%) specific binding was that in the absence of competitors (mean of duplicate tubes) and 0% specific binding was that in the presence of a 50-fold excess of unlabelled G-CSF (mean of duplicate tubes). The bar on the right-hand side of each panel represents the per cent specific binding seen in the presence of 100,000 U of murine GM-CSF (range for triplicate or more tubes).

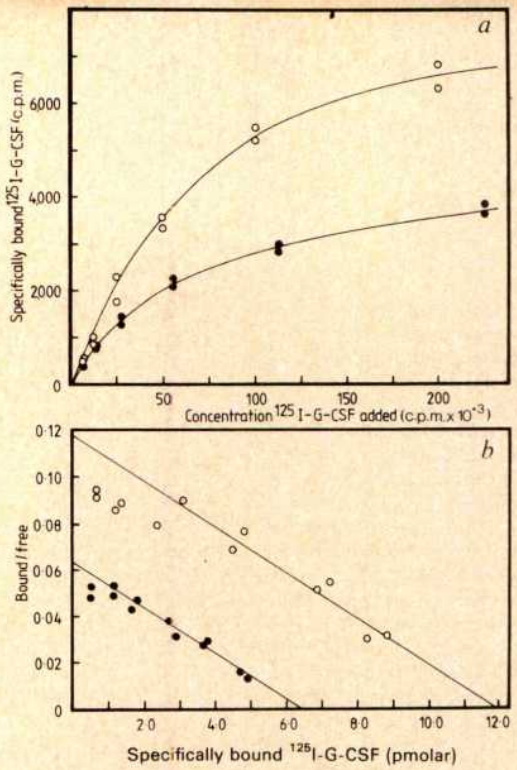

Fig. 5 Saturation analysis of binding of ^{125}I-G-CSF to human AML cells (○) and murine myelomonocytic leukaemic cell line WEHI-3B D$^+$ (●). Specific binding was determined as total binding − nonspecific binding; *a* shows the results of duplicate determinations. *b*, The same data converted to Scatchard plots (specific c.p.m. bound/c.p.m. in the supernatants versus the concentration of ^{125}I-G-CSF specifically bound to cells).

Methods. A freshly obtained bone marrow aspirate from a patient with acute myeloid leukaemia classified as M1 was resuspended in DMEM/FCS, layered over Ficoll/Paque (Pharmacia) of density 1.077 g cm^{-3} and centrifuged at 700*g* for 20 min. The interface cells (>95% leuukaemic blast cells by morphology of stained preparations) were resuspended in DMEM/FCS and passed through a loosely packed, sterile cotton wool plug to remove fat particles. AML cells (2.5×10^6) or WEHI-3B D$^+$ cells (2.0×10^6) were incubated with increasing concentrations of ^{125}I-G-CSF as shown, with or without an excess of unlabelled G-CSF (250 ng ml^{-1}) in DMEM/10% FCS (total volume 170 and 160 μl, respectively) at 37 °C for 1 h in a fully humidified incubator in 10% CO_2 in air. Tubes were then placed on ice, the cells resuspended and layered over 200 μl cold FCS in 0.5 ml flexible plastic centrifuge tubes and centrifuged at 300*g* for 5 min. The tubes were then cut with a scalpel blade a few millimetres above the cell pellet and the pellet and supernatants counted separately in a γ-counter. Nonspecific binding (that in the presence of excess unlabelled G-CSF) was linear with respect to the amount of ^{125}I-G-CSF added and was maximally 15% of the specific binding in these experiments.

Most murine haematopoietic growth factors are inactive on human cells but the species cross-reactivity of murine G-CSF and human CSF-β demonstrated here appears to be quite unambiguous. Human CSF-β and murine G-CSF are both hydrophobic molecules of similar size (relative molecular mass 30,000 and 25,000 respectively) and both are able to stimulate granulocyte colony formation by cells from both species with similar dose–response relationships and similar numbers of target cells responsive to either stimulus. That this represents direct cross-reactivity was indicated by the demonstration of specific binding sites for ^{125}I-G-CSF on human and murine granulocytic cells and the equal abilities of G-CSF and CSF-β to inhibit this binding.

Both molecules also induced differentiation in murine WEHI-3B cells and showed specific binding sites on human myeloid leukaemias. Moreover, CSF-β has been shown to induce differentiation of cells from the human promyelocytic leukaemia cell

Table 1 Specific binding of murine ^{125}I-G-CSF to human normal and leukaemic cells

Type of patient (F.A.B. classification)	Cell source	No. of patients	Specific binding (% of WEHI-3B D$^+$) Mean (±s.d.)	Range
Normal	Bone marrow	5	34±16	17-55
	Blood buffy coat	4	12±11	1-27
	Purified blood neutrophils	5	86±29	45-114
Preleukaemia*	Bone marrow	4	103±55	62-184
Acute promyelocytic	Bone marrow	2		163, 82
leukaemia (M3)†	Blood	1		19
Chronic myeloid	Bone marrow	5	66±26	27-97
leukaemia‡	Blood	3	56±6	52-63
Acute myeloblastic	Bone marrow	9	56±41	18-140
leukaemia (M1+M2)†	Blood	9	30±17	12-56
Acute myelomonocytic	Bone marrow	2		4, 7
leukaemia (M4)†	Blood	2		5, 13
Acute lymphoblastic	Bone marrow	3	4±4	1-8
leukaemia†	Blood	1		<1
Chronic lymphocytic leukaemia§	Blood	3	4±6	−1-10

Leukaemic cells of density $<1.077\ g\ cm^{-3}$ were prepared by centrifugation over Ficoll/Paque (Pharmacia) at 700*g* for 20 min. Normal blood cells comprised unfractionated buffy coat cells. Normal granulocytes were purified from blood by density centrifugation in hypertonic metrizamide gradients[20] and were 95-100% pure. Cells, usually 5×10^6 per incubation, were incubated in duplicate with 90,000-300,000 c.p.m. of ^{125}I-G-CSF with or without a 20-fold excess of unlabelled G-CSF in Dulbecco's modified Eagle's medium (DMEM)/ fetal calf serum (FCS) (70-130 μl total volume) at 37 °C for 1 h. Specific binding (total binding − binding in the presence of unlabelled G-CSF) is expressed as a percentage of the specific binding to an equivalent number of WEHI-3B D$^+$ cells using the same preparation of ^{124}I-G-CSF on the same day.

* Including a patient with refractory anaemia with excess blast cells.

† Acute leukaemic patients were newly diagnosed or in relapse and their density-fractionated cells contained >80% leukaemic blasts.

‡ Cells taken at diagnosis before any treatment.

§ All showed >90% leukaemic lymphocytes.

line HL60 (ref. 18). The frequency of binding sites on leukaemic cells was similar to that on the equivalent normal cells and the apparent binding affinity for ^{125}I-G-CSF appeared to be approximately the same on all the cell types studied. Finally, other studies have shown that G-CSF is able to stimulate various functional activities of post-mitotic neutrophil granulocytes of mouse and man[19].

The strong conservation of G-CSF/CSF-β and their receptors through evolution signals their importance for the maintenance of granulocytic cells in the animal. The conservation of receptors on human granulocytes and myeloid leukaemias indicates that G-CSF and its human analogue, CSF-β, merit further study as regards their possible therapeutic usefulness.

The 5637 cell line was provided by Dr M. A. S. Moore, Sloan-Kettering Cancer Institute, New York. We thank M. A. Vadas and A. F. Lopez for preparing human blood neutrophils. Hybrid antibodies can target sites for attack by T cells

Uwe D. Staerz*, Osami Kanagawa† & Michael J. Bevan*

It would be advantageous in the case of certain diseases to be able to focus a strong T-cell response at a chosen target, for example, in treating cancer or infections that have escaped the normal host response. At present, it seems inconceivable that we could use antigen-specific lines or clones of effector T cells for this purpose because of complications due to the major histocompatibility restriction of T-cell specificity and the problem of rejection of transplanted effector cells. Here we describe a novel technology which combines the power of T lymphocytes in eliminating unwanted cells and causing beneficial inflammatory reactions with the great advantages of monoclonal antibodies (their specificity and availability). We show that heteroconjugates of monoclonal antibodies (referred to hereafter as hybrid antibodies), in which one of the component binding sites is anti-T-cell receptor and the other component binding site is directed against any chosen target antigen, can focus T cells to act at the targeted site. Monoclonal antibodies directed against the T-cell receptor, such as the anti-allotype used here, are mitogenic for resting T cells and can be used to induce effector T cells carrying the T-cell receptor determinant which can then be directed against the target by a hybrid antibody.

Monoclonal antibodies directed against determinants of the T-cell receptor complex of cytotoxic T lymphocytes (CTL) or T-helper cells are able to mimic the effect of antigen in many ways. For example, anti-idiotypes in an appropriate form can

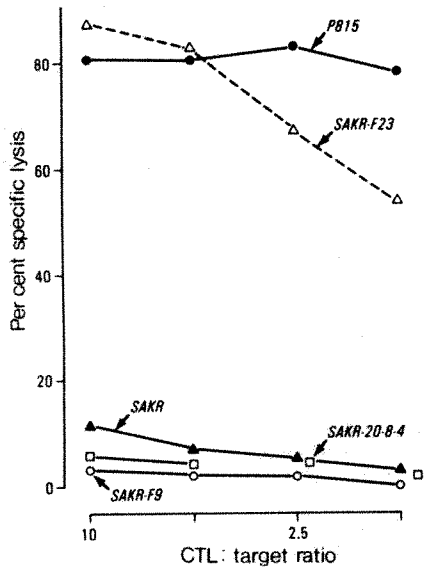

Fig. 1 Anti-receptor allotype monoclonal antibody F23.1 coupled to the target cell surface renders the cell susceptible to lysis by an allotype-positive CTL clone, OE4. F23.1 (IgG2a)[8], F9 (IgG1) monoclonal antibody specific for an idiotypic determinant on CTL clone G4 (ref. 3) and the anti-H-2^b monoclonal antibody 20-8-4 (IgG2a)[15], produced in C3H mice, were purified from ascites fluids on protein A-Sepharose. Antibodies were reacted with the heterobifunctional crosslinker SPDP (Sigma)[16]; a threefold molar excess of SPDP was used to introduce two to three groups per 7S antibody. The modified antibody was then reacted with S.AKR lymphoma cells (H-2^k, Thy-1.1) which had been pretreated with 0.5 mM dithiothreitol to introduce free sulphydryl groups at the cell surface[17,18]. After washing, 1×10^4 pre-labelled (^{51}Cr-labelled sodium chromate) target cells were incubated at 37 °C with twofold serial dilutions of the CTL clone OE4 at 37 °C for 4 h (ref. 3). Per cent specific lysis of these target cells and of P815 (DBA/2, H-2^d) targets was calculated as described elsewhere[3]. The CTL clone OE4 was isolated by limiting dilution from a C57BL/6 (H-2^b) anti-DBA/2 (H-2^d) mixed lymphocyte culture and is maintained by weekly subculture with irradiated DBA/2 spleen cells plus IL-2. OE4 reacts with the anti-allotypic antibody F23.1 and with the anti-H-2^b antibody 20-8-4 but not with the anti-idiotypic F9 antibody. Target cells were: P815 (●), S.AKR (▲), S.AKR coupled to F23.1 (△), S.AKR coupled to F9 (○) and S.AKR coupled to 20-8-4 (□).

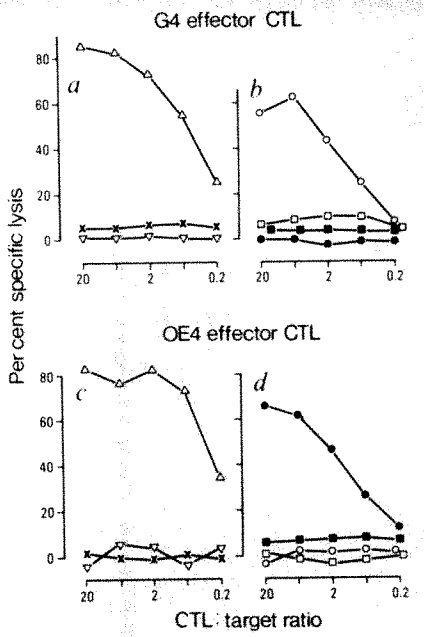

Fig. 2 Heteroconjugates of monoclonal antibodies (hybrid antibodies) can specifically target cells for CTL-mediated lysis. Effector CTL clones were: *a* and *b*, G4 [BALB.B (H-2^b) anti-BALB/c (H-2^d)], which is positive for the idiotypic determinant recognized by F9 (ref. 3), and unreactive with F23; *c* and *d*, OE4 [C57BL/6 (H-2^b) anti-DBA/2 (H-2^d)] CTL clone which is F23$^+$, F9$^-$. Target cells were: P815 (H-2^d, △), S.AKR (H-2^k, ▽), EL4 (H-2^b, ×), S.AKR incubated with 19E12/F23 (●), S.AKR incubated with 19E12/F9 (○), EL4 incubated with 19E12/F23 (■), and EL4 incubated with 19E12/F9 (□).
Methods. The monoclonal alloantibody 19E12 (ref. 11) (IgG2a) specific for the Thy-1.1 alloantigen was purified from ascites fluid on protein A-Sepharose, modified with SPDP[16] and coupled to either F23.1 or F9 monoclonal antibody according to the manufacturer's handbook (Pharmacia). The hybrid antibodies were used to coat ^{51}Cr-labelled EL4 (H-2^b, Thy-1.2) and S.AKR (H-2^k, Thy-1.1) lymphoma cells by incubation at 37 °C for 20 min followed by washing. These target cells plus uncoated ^{51}Cr-labelled S.AKR, EL4 and P815 (H-2^d) targets were assayed for lysis by serial threefold dilutions of CTL at 37 °C for 4 h.

stimulate idiotype-positive T-cell clones to release soluble factors such as interleukin-2 (IL-2)[1,2] or γ-interferon[3] (IFN-γ) and to proliferate[1,2,4]. In addition, recent reports suggest that anti-idiotype on the surface of a cell renders that cell sensitive to recognition and lysis by an idiotype-positive CTL clone: B-cell hybridomas producing anti-idiotype serve as targets for idiotype-positive CTL[5,6], and anti-T3 antibodies (T3 is associated with the T-cell receptor) fixed covalently to cells convert them to sensitive CTL targets (H. Spitz, cited in ref. 7).

Recently, we have produced a murine monoclonal antibody specific for an allotypic determinant present on the T-cell receptor of ~25% of peripheral T lymphocytes[8]. The antibody was generated from a C57L/J mouse that had been hyperimmunized with BALB.B peripheral T cells. This monoclonal antibody, F23.1, seems to be very similar in specificity to a rat monoclonal antibody directed against a T-cell receptor isolated from a T hybridoma[9,10]. To determine whether F23.1, the anti-allotypic monoclonal antibody, could focus CTL onto a target cell, we directly coupled the surface of various cell types to the isolated monoclonal antibody using a heterobifunctional crosslinker. OE4 is a CTL clone of C57BL/6 (H-2^b) origin with lytic specificity for H-2^d-bearing cells. The antigen receptor of clone OE4 bears the allotypic determinant recognized by F23.1. Figure 1 shows that OE4 does not kill cells from the lymphoma S.AKR (derived from AKR/J (H-2^k) mice) in a 4-h cytotoxicity assay, but does efficiently lyse P815 (H-2^d) targets. However, S.AKR cells that had been chemically coupled to F23.1 monoclonal antibody were efficiently lysed by OE4. Target cells coupled to the anti-idiotypic monoclonal antibody F9 (which does not recognize OE4), were insensitive to OE4 effector cells, as were S.AKR cells coupled with an anti-H-2^b monoclonal antibody, 20-8-4, which does react with the H-2^b molecules expressed by OE4. Reciprocal results were obtained with the F9 idiotype-positive, allotype-negative CTL clone G4 (BALB.B (H-2^b) anti-H-2^d). In this case, F9-coupled cells were sensitive targets whereas F23.1- and 20-8-4-coupled cells were not killed (data not shown). Thus, we confirmed that monoclonal antibodies directed against determinants on the T-cell antigen receptor can target cells for attack by CTL when coupled to the surface of the cells. Furthermore, an anti-H-2 monoclonal antibody which reacts with the CTL did not trigger lysis.

We next asked whether heteroconjugates of monoclonal antibodies would be able to specifically target cells for destruction by CTL. In the hybrid antibodies that we constructed, one of the monoclonal antibodies in the hybrid is directed at the T-cell receptor (anti-idiotype or anti-allotype) while the other monoclonal antibody is directed at a surface antigen expressed by the targeted tumour cell but not by the CTL. We chose as the targeting monoclonal antibody 19E12, which is specific for the Thy-1.1 alloantigen[11]. The CTL clones G4 and OE4 both express Thy-1.2 but not Thy-1.1 and do not react with this monoclonal antibody. The target cell was S.AKR (H-2^k, Thy-1.1). We

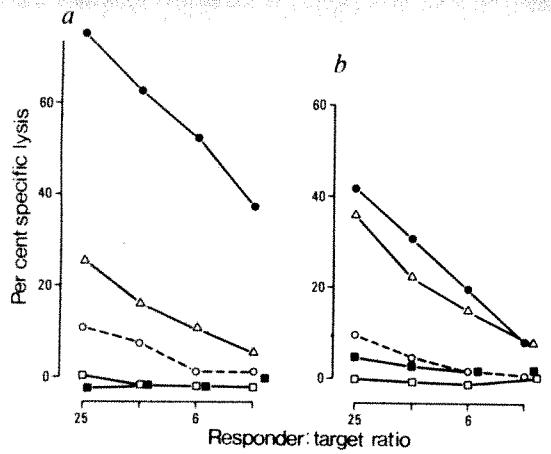

Fig. 3 Cytotoxic effects of Con A-induced (*a*) and F23.1-induced (*b*) spleen cells on various targets. Spleen cells from normal BALB.K (H-2^k) mice were cultured for 4 days at 1×10^6 cells ml^{-1} in RPMI 1640 medium plus 10% fetal calf serum and 10% Con A-induced rat spleen cell supernatant, with either 2.5 $\mu g\ ml^{-1}$ Con A (*a*) or F23.1 monoclonal antibody coupled to Sepharose beads (10^3 beads per ml; *b*). F23.1 cultures also contained 50 mM α-methyl-D-mannoside to block the action of residual Con A present in the rat spleen supernatant. Cells were collected, washed and serial twofold dilutions assayed for lysis of the following ^{51}Cr-labelled target cells: P815 (○), P815 in the presence of 10 $\mu g\ ml^{-1}$ PHA (●), AKR.A1 (□), AKR.A1 cells pre-incubated with 19E12 (anti-Thy-1.1)/F23.1 conjugate (△), and AKR.A1 cells pre-incubated with the 19E12/F9 conjugate (■). AKR.A1 is a T-cell lymphoma derived from an AKR/J mouse which expresses H-2^k and Thy-1.1.

constructed two hybrid monoclonal antibodies using the cross-linker *N*-succinimydyl-3-(1-pyridyldithio) propionate (SPDP). Both hybrid A (19E12/F9) and hybrid B (19E12/F23) worked efficiently and specifically (see Fig. 2). Hybrid A targeted S.AKR cells for lysis by G4 effector cells (Fig. 2*b*) while hybrid B targeted S.AKR cells for lysis by OE4 effector CTL (Fig. 2*d*). Neither hybrid antibody targeted EL4 (H-2^b, Thy-1.2) cells for lysis. Thus, targeting via an antibody combining site works extremely well. Mixtures of unconjugated monoclonal antibodies did not allow target lysis under any circumstances and fractionation of the heteroconjugated monoclonal antibodies on a Sephacryl S-400 column revealed a major peak of specific targeting activity eluting at a relative molecular mass (M_r) of ~300,000, a smaller peak at M_r~500,000 and no targeting activity at lower or higher M_r ranges (data not shown). Other experiments have shown that EL4 cells, which served as the negative control in Fig. 2, can themselves be targeted for lysis by the syngeneic CTL clone OE4 by first infecting them with vesicular stomatitis virus and using an F23/anti-virus G protein monoclonal antibody heteroconjugate.

With regard to potential therapeutic applications of this hybrid antibody targeting technique, it would be beneficial to be able to generate effector T cells carrying a monoclonal antibody-defined receptor determinant from any individual. The anti-allotypic monoclonal F23.1 reacts with ~25% of peripheral T cells (both CTL and non-cytolytic T cells[8,12]), is mitogenic for resting, peripheral T cells from mouse strains which are allotype-positive, and induces effector CTL which bear the allotypic determinant (U.D.S. and M.J.B., unpublished). Figure 3 shows the cytotoxic activity of BALB.K (H-2^k) spleen cells that were induced with either the pan-T-cell mitogen concanavalin A (Con A) or with F23.1 monoclonal antibody coupled to Sepharose beads for 4 days in the presence of exogenous IL-2. Con A induces CTL and T-helper cells regardless of their antigen specificity. The CTL activity can be assayed in an antigen-independent fashion by their ability to lyse any target cell coated with an agglutinant such as Con A or phytohaemagglutinin (PHA)[13]. Figure 3*a* shows that Con A-induced BALB.K cells do not specifically lyse P815 or AKR.A1 (H-2^k, Thy-1.1) targets but do lyse such targets in the presence

Table 1 Monoclonal antibody-induced cytotoxic cells express Thy-1

Target cells	Con A-induced effectors		F23.1-induced effectors	
	C′-treated	Anti-Thy-1+C′	C′-treated	Anti-Thy-1+C′
P815+PHA	76.5	0.4	39.8	−0.6
AKR.A1+19E12/F23	24.2	−0.8	36.7	−0.9

Spleen cells from normal BALB.K mice were cultured for 4 days in the presence of 2.5 $\mu g\ ml^{-1}$ Con A, or F23.1 monoclonal antibody covalently coupled to Sepharose beads plus 10% supernatant of rat spleen cells which had been cultured with Con A for 24 h as a source of IL-2. Cultures not containing Con A also included 50 mM α-methyl-D-mannoside to block the effect of Con A. Cells were collected and treated with complement (C′) alone or with monoclonal anti-Thy-1.2 (ref. 14) plus C′, and surviving cells were assayed for 4 h on ^{51}Cr-labelled target cells. Target cells were P815 in the presence of 10 $\mu g\ ml^{-1}$ PHA or AKR.A1 cells that had been incubated with a hybrid antibody (19E12/F23) for 20 min and washed. AKR.A1 is a T-cell lymphoma from AKR/J mice which expresses H-2^k and Thy-1.1. Spleen cells cultured without a stimulus had <1% of the cytotoxic activity shown here on either target. Assays were performed at a killer/target cell ratio of 25:1 for the C′-treated cells and for the equivalent number of surviving cells from the anti-Thy-1-treated groups. Values are per cent specific lysis of the target cells[3].

of PHA. A fraction of the lytic activity revealed by PHA can also be measured on AKR.A1 cells targeted by the 19E12/F.23 hybrid antibody. In the case of F23.1-induced spleen cells (Fig. 3*b*), PHA plus P815 and the hybrid antibody targeting AKR.A1 cells reveal approximately equal amounts of lytic activity. The levels of lytic activity correlate well with other data showing that the bulk of F23.1-induced T cells express the F23.1 determinant whereas only ~20% of Con A-induced T cells express the F23.1 determinant. As has been shown previously for lectin-induced, lectin-revealed cytotoxicity[13], all of the monoclonal antibody-induced cytotoxicity is sensitive to treatment with anti-Thy-1 antibody plus complement, that is, is due to T cells (Table 1).

Although we do not know whether target cell destruction in this hybrid antibody-directed system proceeds via the same lytic mechanism as in antigen-specific, CTL-mediated killing, we suspect that the mechanism is very similar for the following reasons: first, the T-cell clones that we used are conventional CTL clones (Thy-1^+, Lyt-2^+ cells, whose growth is dependent on a supply of exogenous IL-2 plus periodic antigen stimulation). Second, in the case of Con A-induced effector cells, we have also shown that all of the antibody-directed cytotoxicity is mediated by Lyt-2^+ T cells. Finally, target cell death in this system has the same kinetics and requirement for cell contact as in antigen-specific CTL-mediated lysis.

The results presented here suggest that it is possible to focus a strong T-cell response to a particular target antigen using hybrid antibodies; this could have clinical significance in the rejection of tumour cells or viral infections. One requirement is an antibody against the chosen target, for example, a tumour-associated or viral antigen; the other requirement is an antibody against the T-cell receptor complex. This technique circumvents the failure of the patients' T cells to respond in an effective way to the antigenic challenge (if any) with a specific, histocompatibility locus antigen (HLA)-restricted response. One can envisage inducing the patient's own T cells *in vitro* with an antibody against a receptor determinant, then transferring them back to the patient in the presence of an anti-target/anti-receptor hybrid antibody. We are presently assessing the *in vivo* applications in a murine lymphoma model system, by growing AKR/J (Thy-1.1) T lymphomas in AKR/Cum (Thy-1.2) hosts and using the hosts' own effector T cells and a 19E12/F23 hybrid antibody.

We thank Ian Trowbridge and Keiko Ozato for providing ascites fluids and cell lines. This work was supported in part by USPHS grants CA25803 and AI19335.

The mammalian host defence system can be divided broadly into adaptive and non-adaptive immunity. Adaptive immunity is acquired and is mediated by B and T lymphocytes. Non-adaptive immunity is mediated in part by a small subclass of heterogeneous peripheral blood mononuclear cells. This population, termed null cells, consists of haematopoietic precursors and cells mediating natural killer (NK) activity and antibody-dependent cellular cytotoxicity (ADCC). NK cells are a class of non-adherent, non-phagocytic, rapidly cytotoxic lymphocytes which can efficiently lyse a wide variety of tumour cells[1], virally infected cells[2] and immature cell types of normal origin[3]. Despite the broad range of targets, only a limited number of specificities are thought to be involved in target-cell recognition[4–6]. Morphologically, NK cells are large granular lymphocytes[7,8], but they have been shown to exhibit cell-surface markers characteristic of both T cells[9–11] and monocytes[12], raising doubt over their lineage. The recent cloning of the β-chain of the T-cell antigen receptor[13,14] has now allowed us to investigate whether some NK cells are T-cell-related. We have examined rearrangement and expression of the β-chain of the T-cell receptor in cloned murine NK cell lines and fresh murine NK cell populations, and our results support the hypothesis that a subpopulation of NK cells is related to T cells and provide a basis for examining whether some NK activity is mediated by a small number of T-cell receptors.

DNA from five independent NK cell lines, HY-1 (ref. 15), HY-3 (ref. 15), NKB61A2 (ref. 16), NKB61B10 (ref. 16) and BALB/c NK (ref. 17), was examined for rearrangement of the genes coding for the β-chain of the T-cell receptor. DNA was digested with six restriction enzymes (*Eco*RI, *Pst*I, *Pvu*II, *Hpa*I, *Hin*dIII or *Xba*I) and examined by Southern gel analysis using a radioactive probe derived from the joining ($J_\beta 1$; *Eco*RI, *Pvu*II and *Hpa*I) or constant ($C_\beta 1$; *Hin*dIII, *Hpa*I, *Pst*I and *Xba*I) regions of the mouse genomic T-cell receptor β-chain genes[18].

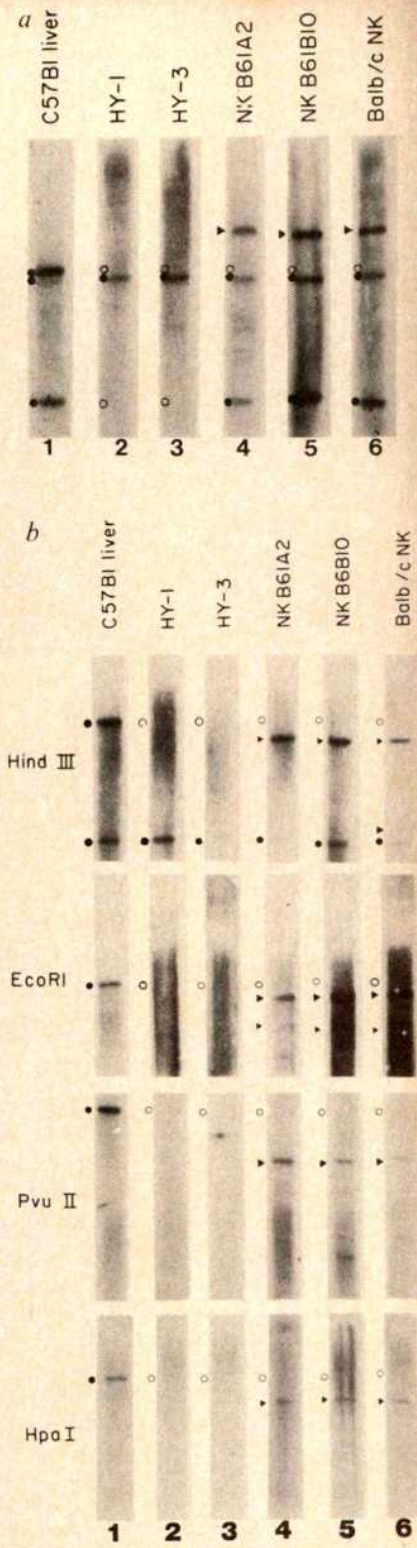

Fig. 1 *a*, Southern blot analysis of DNA from NK cell lines using restriction enzyme *Xba*I. Lane 1, C57BL/6 liver DNA; lane 2, HY-1 DNA; lane 3, HY-3 DNA; lane 4, NKB61A2 DNA; lane 5, NKB61B10 DNA; lane 6, BALB/c NK DNA. *b*, Southern blot analysis of DNA from NK cell lines using T-cell receptor β-chain constant- and joining-region probes. DNA (10 μg) was digested overnight with a 10-fold excess of *Hin*dIII (top panel), *Eco*RI (second panel), *Pvu*II (third panel) or *Hpa*I (bottom panel) (all restriction enzymes from Boehringer Mannheim) and treated as described for *a*, with the exception of the probes. Lane 1, C57BL/6 liver DNA; lane 2, HY-1 DNA; lane 3, HY-3 DNA; lane 4, NKB61A2 DNA; lane 5, NKB61B10 DNA; lane 6, BALB/c NK DNA. Symbols: ●, germline band; ○, bands which have been deleted; ▲, a new, rearranged band.

Methods. *a*, DNA was extracted from the cells using the procedure of Blin and Stafford[24]. DNA (10 μg) was digested overnight with a 10-fold excess of *Xba*I (Boehringer Mannheim) and run on a 6-mm 1% agarose gel (Bio-Rad) at 1.0 V cm^{-1} for 18 h. The DNA was then hybridized with 10^6 c.p.m. ml^{-1} (1 μg of DNA per filter) of nick-translated[25] $C_\beta 1A$ probe of the T-cell antigen receptor β-chain genes for 18 h. $C_\beta 1A$ is the 3.5-kb *Hin*dIII/*Sst*I fragment of *C*1A[18]. This probe contains most of the $C_\beta 1$ coding domains and some 5′-noncoding sequences. Filters were washed and exposed to Kodak XAR-5 films. *b*, *Hin*dIII-digested DNA was hybridized to $C_\beta 1A$ probe (described in *a*) and DNA digested with *Eco*RI, *Pvu*II and *Hpa*I was hybridized to $J_\beta 1$, the insert from the pUCBJ1 subclone of β-chain genes described by Malissen *et al.*[18].

Comparison of the banding pattern of C57BL/6 liver DNA as a control to the NK DNA showed that DNA from all five NK cell lines was rearranged. This result was most evident after digestion by *Xba*I (Fig. 1*a*). There were three germline bands of 5.0, 4.8 and 1.8 kilobases (kb), respectively (Fig. 1*a*, lane 1), and in all cases the 4.8-kb band was retained and the 5.0-kb band deleted. The cell lines HY-1 (Fig. 1*a*, lane 2) and HY-3 (lane 3) had also lost the 1.8-kb band, whereas cell lines

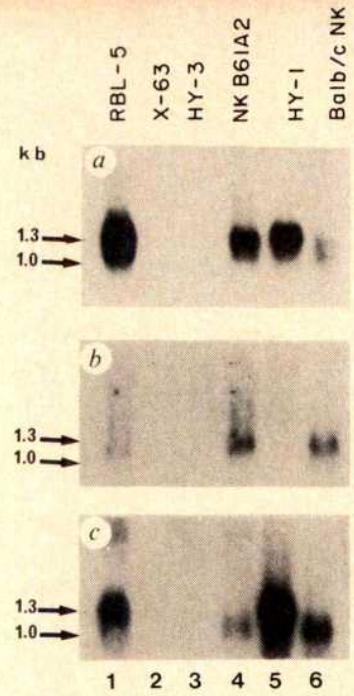

Fig. 2 Northern blot analysis of RNA from NK cell lines using the T-cell receptor β-chain probes. RNA was extracted from cells in the presence of guanidine thiocyanate[26] and 10 μg was treated with glyoxal and electrophoresed through a 1% agarose (Bio-Rad) gel in 10 mM sodium phosphate buffer, *p*H 7.0. Transfer of the RNA to nitrocellulose filters, hybridization and washing were carried out according to the procedure of Thomas[19]. Hybridization was to nick-translated C_β1B (*a*), C_β1U (*b*) or C_β2U (*c*) labelled with ^{32}P-dCTP according to the procedure of Rigby *et al.*[25]. C_β1B is the *Eco*RI/*Eco*RI insert from the pUC8C1B subclone of the cosmid clone 2.3W7 (ref. 18). C_β1U is an ~150-base pair *Eco*RI/*Pst*I fragment consisting of the 3′-untranslated region of C_β1, isolated from RBL-5, a murine cDNA clone[27]. C_β2U is a 2.5-kb *Sst*I/*Sst*I fragment from the cosmid clone 2.3W7[18] which encompasses the 3′-untranslated region of C_β2. Lane 1, RNA from a murine T-cell lymphoma line, RBL-5 (provided by Dr R. Miller); lane 2, RNA from a murine myeloma cell line, X-63 (provided by Dr N. Hozumi); lane 3, HY-3 RNA; lane 4, NKB61A2 RNA; lane 5, HY-1 RNA; lane 6, BALB/c NK RNA.

NKB61A2 (lane 4), NKB61B10 (lane 5) and BALB/c NK (lane 6) had gained a rearranged 6.3-kb band.

We next examined whether either of the two β-chain constant regions was used preferentially in these NK lines. Two probes were used, C_β1A, which hybridizes to both constant regions through the high degree of coding-region homology between them, and J_β1, to confirm that the rearrangement occurs into the first constant region. In the *Hin*dIII digest hybridized to C_β1A probe (Fig. 1*b*, top panel), the 9.8-kb band contained the C_β1 gene whereas the C_β2 gene appeared as a 2.9-kb band (lane 1). In both HY-1 (Fig. 1*b*, lane 2) and HY-3 (lane 3), the C_β1 band had been deleted and no other band appeared, suggesting that the C_β1 gene has been deleted and that C_β2 is the constant region used. In NKB61A2 (Fig. 1*b*, lane 4) and NKB61B10 (lane 5), the C_β1 band was replaced by a 7.8-kb band, and in BALB/c NK (lane 6) the C_β1 band was replaced by 7.8- and 3.5-kb bands. *Eco*RI-digested DNA (Fig. 1*b*, second panel) was hybridized to a J_β1 probe, which does not cross-hybridize to J_β2. The germline band is 9.3 kb (Fig. 1*b*, lane 1). No hybridization was observed to HY-1 (Fig. 1*b*, lane 2) or HY-3 (lane 3) DNA, but in NKB61A2 (lane 4), NKB61B10 (lane 5) and BALB/c NK (lane 6), two new bands of 7.3 and 5.0 kb were found in each lane. DNA digested with *Pvu*II (Fig. 1*b*, panel 3) and *Hpa*I (Fig. 1*b*, bottom panel) was hybridized to J_β1. A single germline band of 11.4 kb (*Hpa*I) or 5.4 kb (*Pvu*II) was replaced by a smaller band of either 9.2 kb (*Hpa*I) or 3.3 kb (*Pvu*II) in NKB61A2, NKB61B10 and BALB/c cell lines.

Table 1 Phenotypic and functional characteristics of spleen cell subpopulations

Sample	Poly-I:C treatment	Selection treatment	NK lytic units per 10^6 cells	% Lyt-1$^+$, 2$^+$ determined by FACS
A	+	None	10	85
B	−	RFC IgG$^+$	210	2
C	+	RFC IgG$^+$	450	1

Enriched and control populations were tested in a 6-h ^{51}Cr-release assay against YAC-1.2 to determine lytic unit values (1 lytic unit is the number of effector cells required for 10% lysis). RFC IgG$^+$, cells forming rosettes with SRBC coated with anti-SRBC were isolated. FACS activity, fluorescence-activated cell sorting using monoclonal anti-Lyt-1, 2 and fluorescein isothiocyanate coupled with F(ab′)$_2$ goat anti-mouse IgG2b.

Our results indicate that all five NK cell lines have undergone rearrangement of the T-cell receptor β-chain genes and that HY-1 and HY-3 have rearrangements into the C_β2 region, whereas NKB61A2, NKB61B10 and BALB/c NK all rearrange into the C_β1 region, with apparently similar rearrangements. We do not know whether these represent similar rearrangements between variable, diversity (*D*) and *J* regions or only between *D* and *J* regions.

We next examined whether RNA homologous to T-cell receptor β-chain genes is expressed in the NK cell lines. Total RNA was isolated from the five NK cell lines, electrophoresed and hybridized, after blotting, to one of three probes: C_β1B, which contains the coding region of C_β1 and some 5′-noncoding sequences; C_β1U, which is a fragment from RBL5 (ref. 18) containing the 3′-untranslated region of C_β1; or C_β2U, containing the 3′-untranslated region of C_β2.

Figure 2*a* shows a Northern blot[19] in which C_β1B was used as a probe; NKB61A2 (lane 4), HY-1 (lane 5), BALB/c NK (lane 6) and NKB61B10 (data not shown) expressed a relatively high level of the β-chain messenger RNA, comparable with that of mouse T-cell lymphoma line RBL-5 (lane 1) used as a control. The B-cell line X-63 (Fig. 2*a*, lane 2), used as a negative control, expressed no C_β1-homologous RNA . HY-3 (Fig. 2*a*, lane 3) expressed a lower level of β-chain mRNA which could be detected only after a longer exposure. Examination of the HY-3 NK cells also revealed a significant decrease in NK killing activity (K.R., unpublished data). Figure 2*b*, *c* shows that BALB/c NK and NKB61A2 express a 1.3-kb C_β1 mRNA and a 1.0-kb C_β2 mRNA, whereas HY-1 and HY-3 seem to express only a 1.3-kb C_β2 mRNA. The NKB61B10 line expressed a 1.3-kb mRNA from the C_β1 region (data not shown). In each case, a full-length 1.3-kb mRNA, presumably containing *V*, (*D*), *J* and *C* sequences[20], was detected. Moreover, the constant regions used in these full-length messages agreed with the data on DNA rearrangement. There was no apparent preference for either of the two constant-region genes in these NK cell lines. The lack of correlation between the presence of a 1.0-kb mRNA and the results of the DNA rearrangement analysis is not surprising, as expression of this short mRNA is known to occur only with *D*–*J* rearrangement[21,22] or no rearrangement at all[20].

To examine whether freshly isolated NK cells also possess these T-cell-like properties, we isolated NK cells from normal mice and from mice stimulated with polyinosinic: polycytidylic acid (poly-I:C). Spleen cells from CBA/J mice were passed over nylon wool columns and NK cells were isolated by recovering cells that form rosettes with sheep red blood cells (SRBC) pretreated with monoclonal IgG2b anti-SRBC antibody. This treatment resulted in a >10-fold increase in the cytolytic activity (lytic units at 10% lysis) against YAC targets and the cells contained <2% Lyt-1$^+$, Lyt-2$^+$ cells as judged by fluorescence-activated cell sorter (FACS) analysis (see Table 1).

Figure 3 shows Northern blot analysis of RNA from these cells. RNA from spleen cells passed over the nylon wool column hybridized to the C_β1B probe for the T-cell receptor (Fig. 3*a*), as the population consists largely (85%) of T cells. The results indicate that enriched NK cells which have not been stimulated

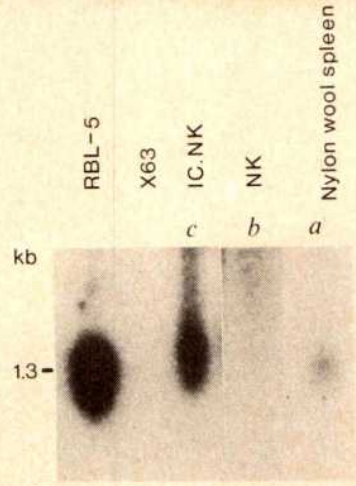

Fig. 3 Northern blot analysis of RNA from NK cells freshly isolated from spleen cells, using T-cell receptor β-chain gene probes. CBA/J mice (4–8 weeks old, $n = 100$) were injected intraperitoneally with 100 μg (0.1 unit) of poly-I:C (Miles Laboratories) per mouse, 24 h before assay (poly-I:C-stimulated mice). A further 100 CBA/J mice were untreated to provide the unstimulated group. Pooled spleen cells were passed over nylon wool columns (*a*), and enriched for NK cells, by direct rosetting with IgG2b-treated SRBC of unboosted (*b*) or poly-I:C-boosted cells (*c*). Nylon-wool-passed cells were rosetted for 1 h at 20 °C with 1% SRBC precoated with 1/50 monoclonal IgG2b anti-SRBC antibody (clone sp2/HL), as described previously[28]. Rosette-forming cells (RFC) were layered onto Ficoll-Hypaque (1.085 g ml^{-1}) and centrifuged for 20 min at 850*g*. Lymphocytes were isolated from the pellet by hypotonic shock. RNA was extracted from 3×10^6 cells and Northern blot analysis was carried out as described in Fig. 2 legend.

with poly-I:C contain very little RNA homologous to the T-cell receptor β-chain (after prolonged exposure) (Fig. 3*b*). However, when poly-I:C-treated spleen cells were enriched and purified for NK cells (Fig. 3*c*), they were found to contain a mRNA of the same size as that of the positive control samples (RBL-5 RNA and spleen T cells; Fig. 3*a*). These preliminary results indicate that freshly isolated NK cells, especially poly-I:C-boosted NK cells, may contain mRNA homologous to the β-chain of the T-cell receptor. It is possible that poly-I:C treatment enriched a population of T-cell-like NK cells, but it is unlikely that the presence of the β-chain mRNA can be attributed to contaminating T cells, as they make up less than 2% (one experiment contained no detectable T cells) of the cell population (Table 1).

We demonstrate here that murine NK cells rearrange and express RNA of the T-cell receptor β-chain genes in five murine NK cell lines and in some cells possessing NK activity which were freshly isolated from murine spleens. These results suggest that at least some NK cells are closely associated with the T-cell lineage. Although HY-1 and HY-3 have been identified as cytotoxic T-cell clones, the others were never so identified. The expression of T-cell receptor-homologous mRNA suggests that the protein product of the rearranged genes may be expressed at the NK cell surface. The finding of a recognition structure, NKTa (relative molecular mass 90,000), on a human NK cell line, which seems to be responsible for its cytolytic activity[23], is consistent with these observations. These findings, however, do not suggest that all NK cell activity can be attributed to T-cell-like NK cells or that the T-cell receptor is necessarily responsible for all NK target cell recognition. The data, however, provide a basis for further examination of whether a limited number of functional rearrangements do indeed occur in these NK cells and also if the rearranged T-cell receptor genes code for a receptor that mediates recognition by NK cells.

We thank Ms Carol Baubock and Ms Rita Campbell for technical help. This work was supported by the NCI and MRC of Canada, Y.Y., B.T., J.R. and K.R. are recipients of awards from the MRC of Canada. Rearrangements of the cellular p53 gene in erythroleukaemic cells transformed by Friend virus

Michael Mowat*, Ambrose Cheng, Nobuhiro Kimura, Alan Bernstein & Samuel Benchimol†

Division of Biological Research, Ontario Cancer Institute, and the Department of Medical Biophysics, University of Toronto, 500 Sherbourne Street, Toronto, Ontario, Canada M4X 1K9

There is now good evidence that the cellular protein, p53, is involved in the transformation process, although its precise role is unknown[1]. It was reported recently that expression of the p53 gene can immortalize cells[2] and that the p53 gene can replace the *myc* oncogene in a *myc–ras* immortalization/transformation assay[3,4]. We have investigated whether p53 is involved in the progression towards the neoplastic state *in vivo* and report here that erythroleukaemic cell lines transformed by different isolates of Friend leukaemia virus show altered expression of the cellular p53 gene. High levels of p53 protein are found in certain lines, but the protein is undetectable in others. This heterogeneity in p53 gene expression is associated with heterogeneity in tumorigenicity. We demonstrate that genomic rearrangements are responsible for p53 gene inactivation in these cell lines and that they occur *in vivo* during the natural progression of Friend virus-induced erythroleukaemia.

Friend leukaemia virus is a complex of two viruses, a replication-defective spleen focus-forming virus (SFFV) and a replication-competent Friend murine leukaemia virus (F-MuLV)[5]. Clonal cell lines transformed by Friend virus were established from methylcellulose colonies derived from individual spleens of Friend virus-infected mice (see Table 1). To test for the presence of p53 protein in these cell lines, cultures were metabolically labelled with ^{35}S-methionine. p53 was immunoprecipitated from cellular extracts, subjected to electrophoresis in SDS-polyacrylamide gels and visualized following autoradiography (Fig. 1). Most (24/31) of the cell lines expressed p53. Of the remaining seven lines, five did not express detectable p53 protein and two expressed a truncated p53-related protein of relative

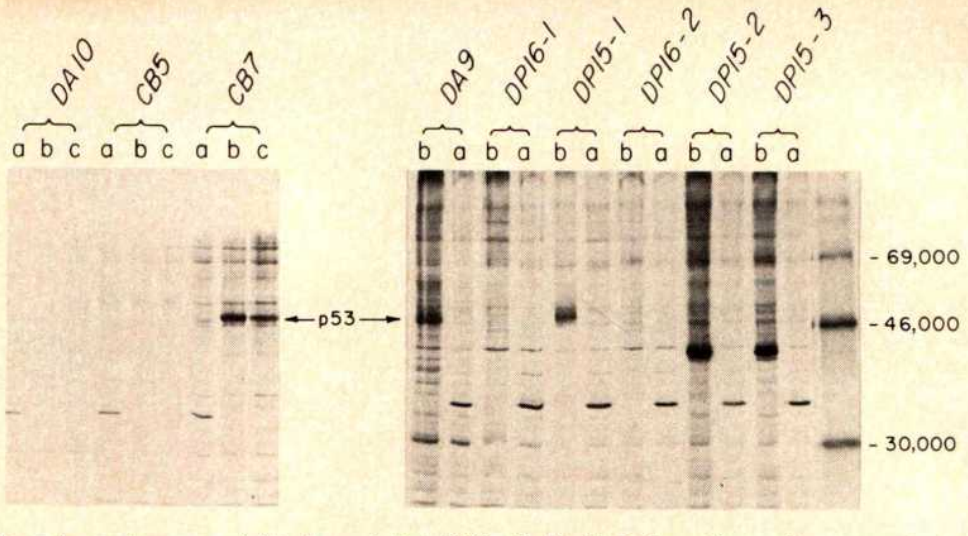

Fig. 1 p53 synthesis in Friend virus-transformed cell lines. Lane *a*, PAb419 (ref. 6) (control monoclonal antibody); lane *b*, PAb421 (ref. 6); lane *c*, RA3-2C2 (ref. 7). Approximately 10^7 cells were labelled for 2 h at 37 °C with 0.2 mCi of ^{35}S-methionine in 0.5 ml α-medium lacking methionine. Cells were then washed with PBS and lysed for 30 min on ice with 0.3 ml lysis buffer (1% Nonidet P-40 (NP40), 150 mM NaCl, 50 mM Tris *p*H 8). Lysates were cleared by centrifugation for 1 min and by the addition of 0.5 ml of a 10% suspension of formalin-treated *Staphylococcus aureus* Cowan 1 cells (Immunoprecipitin, BRL) for 15 min on ice, followed by centrifugation and retention of the supernatant. Lysate volumes corresponding to equal numbers of trichloroacetic-acid-insoluble counts (10^7 c.p.m.) were immunoprecipitated overnight at 10 °C with 40 μl hybridoma tissue culture supernatant in 400 μl NET/gel buffer (150 mM NaCl, 5 mM EDTA, 50 mM Tris *p*H 7.4, 0.05% NP40, 0.02% sodium azide, 0.25% gelatine). Immune complexes were collected on 50 μl *S. aureus* cells as above, washed twice in NET/gel buffer and then eluted into 30 μl sample buffer (2% SDS, 10% glycerol, 0.1% bromophenol blue, 25 mM Tris *p*H 6.8) by heating at 70 °C for 10 min. *S. aureus* cells were removed by centrifugation and samples were loaded onto a 12.5% polyacrylamide gel in the presence of SDS. Electrophoresis was at 35 mA until the blue dye front reached the bottom of the gel. Gels were fixed in 7.5% acetic acid/25% methanol for 30 min before drying and exposure to Kodak XAR-5 film.

molecular mass (M_r) ~44,000. These results were confirmed using other monoclonal antibodies recognizing different epitopes on the p53 molecule. The truncated p53-related peptide was recognized by all the monoclonal antibodies tested (data not shown), PAb421 (ref. 6), RA3-2C2 (refs 7, 8), 200.47 (ref. 9) and PAb122 (ref. 10). Note that the cell lines were derived from the spleens of 10 mice and that some lines may, therefore, be sibling clones. The seven lines showing aberrant expression of p53 were derived from four different mice. Thus, the infected spleens from 4 out of 10 mice gave rise to cell lines displaying aberrant p53 expression.

To estimate the steady-state levels of p53 protein in the various cell lines, p53 was immunoprecipitated from increasing amounts of cell extracts and analysed by the Western blotting technique[11]. p53 is detected quantitatively by this procedure (Fig. 2*A*, *B*). A representative autoradiograph shown in Fig. 2*C* confirms the conclusions obtained by metabolic labelling. In cells where p53 protein synthesis was not detected by metabolic labelling, there was at least 100-fold less p53 than in p53-positive Friend cells. p53 was not detected in normal spleen cells (data not shown).

To determine whether the absence of p53 expression, or the synthesis of the antigenically related 44,000-M_r protein, was the result of rearrangement or loss of the cellular p53 gene, genomic DNA from these Friend cell lines was analysed by the Southern blot technique. The probe used, a complementary DNA clone (clone 9 or p27.1a) containing mouse p53-specific sequences[12,13], hybridized to 16.0- and 3.3-kilobase (kb) fragments in *Eco*RI-digested normal mouse DNA or DNA from all the Friend lines expressing p53 (Fig. 3*C*, lanes *b*, *c*, *f*, *j*). The 3.3-kb DNA fragment has previously been shown to contain a p53 pseudogene[14], whereas the 16.0-kb fragment contains the entire

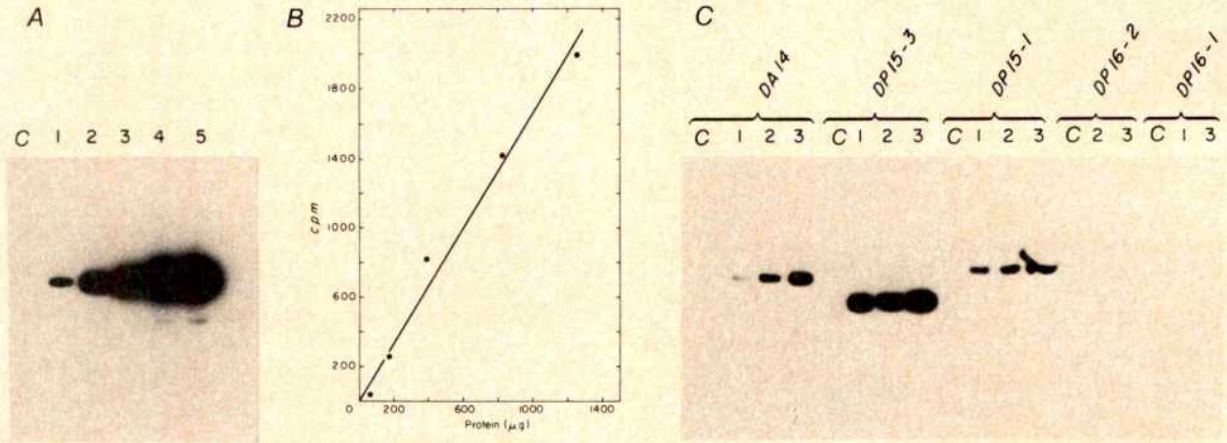

Fig. 2 Quantitative analysis of p53 protein using the Western blotting technique. *A*, Autoradiograph of the blot. Increasing amounts of cell extract prepared from CB7 cells as in Fig. 1 were immunoprecipitated with an excess of PAb421 monoclonal antibodies against p53[6]. Lanes 1–5 contain 100, 200, 400, 800 and 1,200 μg of protein, respectively. Lane *c* contains 400 μg protein immunoprecipitated with a control monoclonal antibody. The number of ^{125}I counts bound to the nitrocellulose paper was measured in a γ-counter and used to generate the dose-response curve shown in *B*. Linear regression analysis was used to fit the best curve to the data. *C*, Increasing amounts of cell extract prepared from several Friend virus-transformed cells were treated as in *A*; lanes 1–3 contain 50, 100 and 200 μg protein, respectively. Lane *c* contains 100 μg protein immunoprecipitated with a control monoclonal antibody. Western blot hybridization was performed essentially as described by Burnette[11] except that immunoprecipitates, instead of crude extracts, were applied to SDS-polyacrylamide gels and then transferred to nitrocellulose. Electroblotting was carried out at 7–8 V cm^{-1} for 6 h. The nitrocellulose was reacted with anti-p53 antibodies (PAb421) and radioiodinated affinity-purified *S. aureus* protein A (Amersham).

Table 1 Tumorigenicity, spleen colony formation and presence of p53 in various Friend virus-transformed cell lines

Cell lines	Presence of p53 (%)	No. of cells injected	Spleen colonies per 10^5 cells	Tumours/ mice injected	Tumour size
DA9	60	10^4	—	6/8	+++
		10^5	26	3/3	+++
		10^6	—	3/3	+++
DA10	<1	10^4	—	8/8	++
		10^5	25	2/3	++
		10^6	—	3/3	++
CB7	100	10^4	—	7/8	+++
		10^5	20	3/3	+++
		10^6	—	3/3	+++
CB5	<1	10^4	—	2/10	++
		10^5	18	—	—
		10^6	—	0/2	—
CB3	<1	10^4	—	1/8	+
		10^5	15	1/3	+
		10^6	—	0/3	—
DP15-1	100	10^4	ND	5/5	+++

DP15-3	<1*	10^4	ND	5/5	+++
DP16-1	<1	10^4	ND	2/5	++
DP16-2	<1		ND	ND	—

The cell lines were established from methylcellulose colonies derived from individual spleens of Friend virus-infected mice as described previously[19]. Cells were maintained in α-medium supplemented with 10% fetal calf serum. Virus stocks of the polycythaemia- and anaemia-inducing strains of Friend virus complex (FV-P and FV-A, respectively) were obtained as follows. NIH 3T3 fibroblasts non-productively infected with the anaemia-[23] or polycythaemia[24]-inducing strains of Friend spleen-focus-forming virus ($SFFV_A$ and $SFFV_P$) were superinfected with cloned Friend murine leukaemia virus (F-MuLV). F-MuLV was obtained from the tissue culture supernatant of NIH 3T3 cells that had been transfected with F-MuLV DNA clone 57 (ref. 25). Cell lines designated DA and DP were derived from FV-A- or FV-P-infected mice, respectively. The cell lines CB3, CB5 and CB7 were derived from newborn BALB/c mice infected with F-MuLV[26]. All other cell lines were derived from DBA/2J mice infected as adults with either FV-A or FV-P. Cell lines with the same number, for example, DP15-1, -2, -3, were derived from different methylcellulose colonies from the same mouse spleen. Cell lines CB3 and CB5 were derived from the same mouse. The presence of p53 protein was determined by the Western blotting technique (see Fig. 2 legend). The amounts are relative to cell line CB7. To count spleen colonies, irradiated (850–900 rad) mice were injected with 10^5 cells in phosphate-buffered saline (PBS). Spleens were removed 9 days later, fixed in Bouin's solution and the colonies counted. The number shown is the average of two spleens. ND, not determined. +++ Refers to large tumours which developed at the site of subcutaneous injection within 2–4 weeks; ++, smaller tumours which developed within 3–6 weeks; +, small tumours which developed 2–3 months after injection.

* These cells contained no detectable p53 protein but did contain high levels of an antigenically related protein of 44,000 M_r that was recognized by monoclonal antibodies to p53 (see Figs 1, 2).

functional p53 gene[15]. Similarly, *Bam*HI or *Hin*dIII digestion of either normal mouse DNA or DNA from p53-producing Friend cell lines resulted in two DNA fragments of 9.0 and 6.0 kb for *Bam*HI and 7.6 and 2.0 kb for *Hin*dIII which hybridized to the p53 probe (Fig. 3*A*, lanes *b*, *c*, *f*, *k*; *B*, lanes *b*, *d*). Thus, at this level of resolution there are no detectable rearrangements of the p53 gene in p53-producing Friend cell lines.

We next examined the seven cell lines that failed to express p53 protein. Digestion of cellular DNA of clone DA10 with the enzymes *Eco*RI, *Bam*HI or *Hin*dIII revealed no rearrangement of the p53 gene (Fig. 3*A*–*C*, lanes *a*). However, p53 mRNA was not detected by Northern gel analysis[16] (data not shown). Thus, the absence of p53 protein can be explained by a transcriptional block in the expression of the p53 gene. In contrast, the other cell lines contained p53 DNA fragments of different sizes. Cell

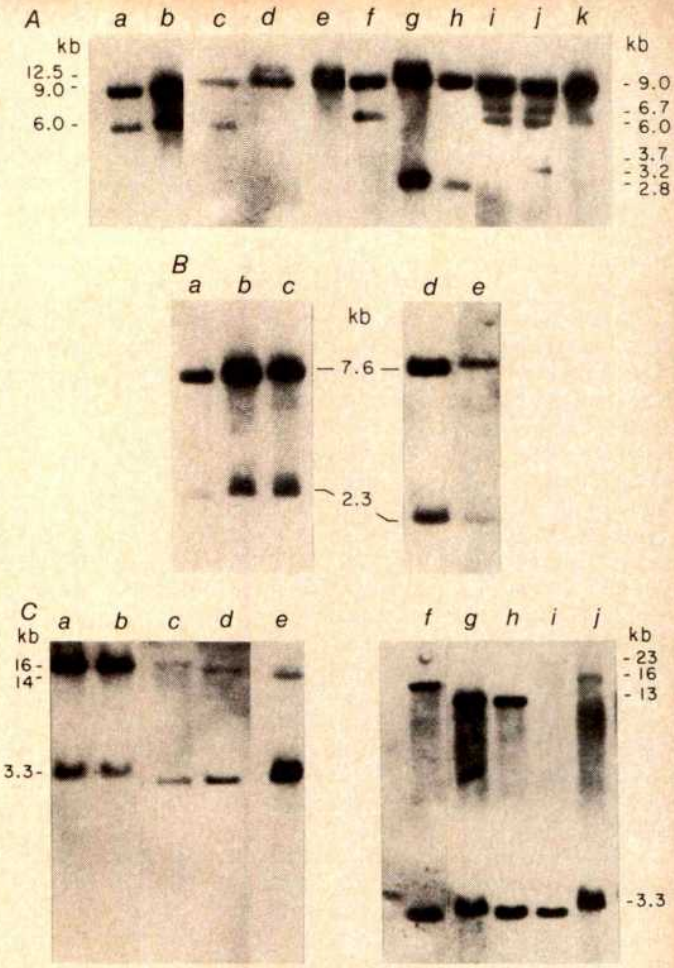

Fig. 3 Genomic DNA blots of Friend virus-transformed cell lines. p53-specific sequences were detected using a p53 cDNA plasmid clone as probe[12,13]. *A*, Genomic DNA from the following cell lines was digested with *Bam*HI: *a*, DA10; *b*, DA9; *c*, CB7; *d*, CB5; *e*, CB3; *f*, DP15-1; *g*, DP15-2; *h*, DP15-3; *i*, DP16-1; *j*, DP16-2; *k*, DP16-3; DP16-3 is a p53-producing cell line. *B*, Genomic DNA from the following cell lines was digested with *Hin*dIII: *a*, DA10; *b*, DA9; *c*, CB3; *d*, CB7; *e*, CB5. *C*, Genomic DNA from the following cell lines was digested with *Eco*RI: *a*, DA10; *b*, DA9; *c*, CB7; *d*, CB5; *e*, CB3; *f*, DP15-1; *g*, DP15-2; *h*, DP15-3; *i*, DP16-2; *j*, DP16-3.

Methods. DNA was isolated on guanidinium isothiocyanate CsCl gradients[27]. CsCl (1 g ml^{-1}) was added to the cell lysate in guanidinium isothiocyanate. The lysate was then loaded on a 5.7 M CsCl cushion and spun at 25,000 r.p.m. for 24 h in a SW27 rotor. The viscous DNA above the cushion was dialysed against TE (10 mM Tris *p*H 8.0, 1 mM EDTA), then extracted with phenol/chloroform. The DNA was precipitated with ethanol, spooled on a glass rod and resuspended in TE and dialysed against TE. DNA was digested and electrophoretically separated in agarose gels as described previously[28]. The DNA in the gels was acid depurinated by the technique of Wahl *et al.*[29], before transfer to zeta probe filters (AMF Corporation) as described by Southern[30]. The filters were hybridized to 1×10^6 c.p.m. ml^{-1} of nick-translated[31] p53 cDNA plasmid[12,13] in 50% formamide and 10% dextran sulphate for 16 h at 42 °C. The final wash was at 50 °C in 0.1% sodium lauryl sulphonate and 0.1 × SSC (1 × SSC = 0.15 M NaCl plus 0.015 M sodium citrate).

lines CB5, CB3, DP15-2 and DP15-3 have lost both alleles corresponding to the normal 6.0-kb *Bam*HI fragment (Fig. 3*A*, lanes *d*, *e*, *g*, *h*); instead, p53 fragments of ~12.5 kb were observed after *Bam*HI digestion of CB3 or CB5 DNA. Similarly, digestion of DP15-2 and DP15-3 DNA with *Bam*HI produced a p53 DNA fragment of 2.8 kb (Fig. 3*A*, lanes *g*, *h*). Digestion of DNA from these same cell lines with *Eco*RI confirmed both the presence of a rearrangement in the functional p53 gene and the loss of the normal homologous allele (Fig. 3*C*).

Cell clone DP16-2 also has a rearranged p53 gene, as demonstrated by the loss of the 16-kb *Eco*RI fragment and the appearance of a novel 23-kb DNA fragment (Fig. 3*C*, lane *i*). Digestion of DP16-1 and DP16-2 DNA with *Bam*HI resulted in a complex pattern of p53 DNA fragments (Fig. 3*A*, lanes *i*, *j*), suggesting that independent and different genomic rearrangements occurred at each homologous allele to inactivate the p53 gene. Structural alterations in the p53 pseudogene were not observed. We conclude that rearrangement of the p53 gene is involved in gene inactivation and in the production of the truncated 44,000-M_r protein.

Because several Friend lines examined here were established from methylcellulose colonies derived from the same mouse, we were able to investigate whether independent *in vitro* colonies were clonally related by examining their unique p53 rearrangements. For example, cell lines DP15-2 and DP15-3 are derived from the same DBA mouse infected with FV-P. These cell lines both express a 44,000-M_r protein antigenically related to p53 and have an identical rearrangement of their p53 gene. Similarly, cell lines DP16-1 and DP16-2 share identical rearrangement of their p53 gene (but different from DP15-2 and DP15-3). Cell clones CB3 and CB5 are also derived from the same BALB/c mouse and share identical rearrangement of their p53 gene and common F-MuLV integration sites (data not shown). The presence of unique p53 rearrangements in more than one cell line derived from the same mouse suggests that the genomic p53 rearrangements described here occurred *in vivo* and were not an artefact of cell culture. Thus, we conclude that the genomic rearrangements must have conferred selective advantage on these cells during the natural progression of Friend disease *in vivo*.

It has previously been reported that expression of p53 protein is associated with tumorigenicity in Abelson virus-transformed lymphoid cell lines[17,18]. The availability of Friend cell lines differing in p53 expression allowed us to investigate whether this heterogeneity was reflected in tumorigenic phenotype. Table 1 compares the ability of the various Friend virus-transformed cell lines to form subcutaneous tumours in syngeneic adult mice. BALB/c mice injected subcutaneously with the p53 producer cell line CB7 had large tumours, whereas no tumours were detected after injection with either of the p53 non-producer cell clones CB3 or CB5. After longer latency periods (1.5–3 months), occasional tumours were observed in these mice. None of the tumours formed by CB3, CB5 or CB7 regressed.

The efficiency of tumour formation by the p53 non-producer cell line DA10 was similar to that observed with the p53 producer cell DA9, although there was a 1–2-week delay in the time when tumours were first detected with DA10. Also, DA10 tumours were much smaller than tumours formed by DA9.

To investigate whether the differences in tumorigenicity between the p53 producer and non-producer Friend cell lines reflected differences in the immunogenicity or *in vivo* growth requirements of these cells, rather than a direct effect of p53 on tumour phenotype, we utilized the fact that Friend virus-transformed cell lines are able to form spleen colonies in irradiated syngeneic hosts[19,20]. No differences were observed in either the spleen colony-forming efficiency or spleen colony size between p53 producer and p53 non-producer cell lines (Table 1).

To determine whether the tumours that formed from p53 non-producer cell lines were variants or revertants that had now acquired the ability to express p53 protein, we analysed the subcutaneous tumours formed by p53-negative and -positive cell lines by the Western blotting technique. No p53 protein was detected in tumours formed by cell lines DA10, CB3, CB5 and DP16-1, whereas p53 was detected in tumours from cell lines CB7 and DA9 (data not shown). Thus, expression of p53 protein is not essential for tumour formation *in vivo*; rather, the presence of this protein in Friend virus-transformed cells seems to enhance their tumour phenotype.

Because high levels of p53 protein have been reported previously in four different Friend cell lines[21], we were surprised to find no p53 expression in cell lines derived from the infected spleens of three mice. The cell lines used in the previous study were all derived after subcutaneous passage of transplantable tumours whereas the Friend virus-transformed cell lines examined in our study were from colonies obtained by plating spleen cells from mice infected with Friend virus in methylcellulose. Thus, unlike the earlier study[21], there was no direct selection for tumorigenicity placed on the cell lines used here.

The high frequency of p53 gene inactivation and rearrangement observed in Friend erythroleukaemic cells is intriguing and unexpected. Moreover, it suggests that inactivation of the p53 gene is not a random event, but is closely associated with the induction of erythroleukaemia by Friend virus complex or its helper virus. Note, however, that in the p53-producing cell lines examined here, the amount of p53 protein is at least 100-fold higher than in normal spleen cells. Thus, transformation of erythroid cells by Friend virus is accompanied by major changes in the regulation of p53 protein levels—p53 protein levels may rise ~100-fold or expression of the p53 gene may be completely shut-off through gene inactivation. In the latter case, neither cell division nor immortalization functions seem to be affected.

We cannot explain why many tumour cells express high levels of p53 protein whereas some of the Friend cell lines described here, as well as an Abelson virus-transformed cell line described previously[22], have genomic rearrangements leading to p53 gene inactivation. Resolution of this paradox may provide some insights into the roles of p53 in normal and malignant cells.

α-Interferon-induced transcription of HLA and metallothionein genes containing homologous upstream sequences

Richard L. Friedman* & George R. Stark†

Complementary DNAs corresponding to the interferon (IFN)-induced messenger RNAs for histocompatibility locus antigens (HLA), metallothionein-II (MT2), 2′,5′-oligoadenylate synthetase and about eight other proteins of unknown sequence have been isolated recently[1–5], and by interferon regulation of transcription has been demonstrated for several ofthe eight mRNAs[3,4], with a significant increase apparent in as little as 5 min[3]. We now show that IFN-α treatment results in a three- to fivefold increase in the transcription of *MT2* and *HLA* class I genes in human T98G neuroblastoma cells. Furthermore, comparison of regions upstream of the *MT2A* gene, two *HLA* genes and one *HLA* class II gene reveals a homologous sequence of ~30 base pairs (bp) which may be involved in regulating transcription of interferon-induced genes. Transcription of the mRNA for human *MT2A* is induced by glucocorticoids or metal ions[6,7] and the regulatory elements have been mapped by promoter-fusion experiments[8]. We now show that the rate of transcription of *MT2A* is the same on treatment with interferon or dexamethasone, but that the mRNA accumulates much faster with dexamethasone, indicating that post-transcriptional events are important in the latter case.

We determined relative rates of transcription in isolated nuclei by hybridizing ^{32}P-labelled RNA, synthesized in run-off transcription reactions, to cDNA probes bound to nitrocellulose filters. The assay measures the relative number of transcriptional complexes initiated on genes corresponding to the complementary DNA probes (see ref. 3 for experimental details and discussion of this method). To measure transcription from *HLA* class I genes, we used plasmid pABC001 (ref. 9), containing *HLA-B7* cDNA that hybridizes to *HLA-A*, *HLA-B* and *HLA-C* mRNAs. The *1-8* and *MT2* cDNAs used were isolated by Friedman *et al.*[3]. A full-length human β-actin cDNA[10] was used as a control in all experiments.

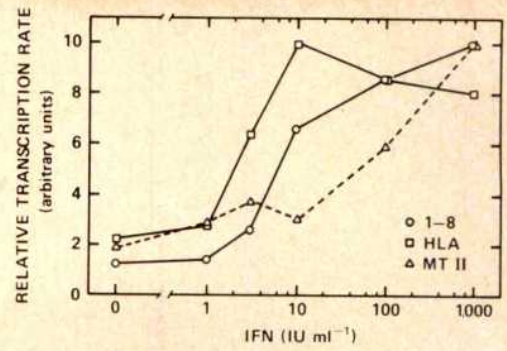

Fig. 1 Dependence of transcription on IFN-α concentration. T98G cells were treated with IFN-α for 2 h and relative transcription rates were measured in the nuclear run-off assay. Duplicate assays agreed to ±20%. To facilitate comparisons, the highest point in each assay was assigned a relative rate of 10. T98G human neuroblastoma cells were grown as described previously[3]. Wellferon, a highly purified mixture of IFN-α, specific activity $1–2\times10^8$ IU ml^{-1} (ref. 23), was used in all experiments. Transcription assays were modified slightly from those used by Friedman *et al.*[3] in that hybridizations were carried out in a volume of 300 μl, containing 1.5×10^7 c.p.m. of ^{32}P-labelled RNA.

Interferon-induced transcription of *1-8*, *HLA* and *MT2* in a dose-dependent manner (Fig. 1), while transcription of the β-actin gene was not affected by any IFN-α concentration tested. Half-maximal induction of *MT2* transcription required 30 times more IFN-α than similar induction of *HLA* genes. We have shown previously that the accumulation of six mRNAs is a function of interferon concentration over a wide range and that the concentration of IFN-α for half-maximal induction is different for different mRNAs. The accumulation of *MT2* mRNA requires a higher concentration of IFN-α than any of the others[3]. We conclude that dose-dependent changes in transcription rate account, at least in part, for the dependence of mRNA accumulation on interferon concentration.

When cells were treated for 13 h with 1,000 IU ml^{-1} IFN-α, the transcription rates of *1-8*, *MT2* and *HLA* genes were about half those observed after 2 h of treatment (Fig. 2*a*). For the *1-8* gene, the extent of this decrease was less than we reported previously[3] at a lower IFN-α concentration (100 IU ml^{-1}), suggesting that the degree of down-regulation of *1-8* transcription may depend on the concentration of IFN-α. We used 1,000 rather than 100 IU ml^{-1} of IFN-α in the current experiments to obtain maximum induction of *MT2*.

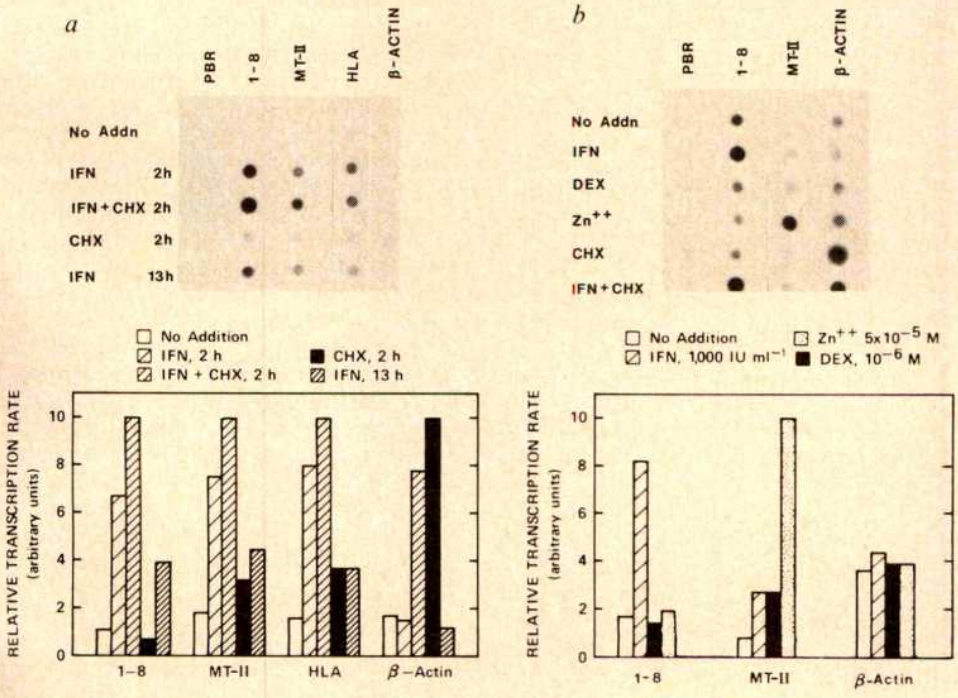

Fig. 2 *a*, Effect of inhibiting protein synthesis or prolonging treatment with IFN-α on interferon-induced transcription. The results of duplicate experiments were averaged. The values agreed to ±15% except for *HLA* genes in cycloheximide (CHX)-treated cells, where the duplicates agreed to ±50%. *1-8* and β-actin served as positive and negative controls, respectively. The concentration of IFN-α was 1,000 IU ml^{-1}. Cycloheximide was used at 32 μg ml^{-1}, a concentration that inhibits protein synthesis in T98G cells by >95%[3]. *b*, Effects of IFN-α (1,000 IU ml^{-1}), dexamethasone (DEX, 1 μM) and Zn^{2+} (50 μM) on transcription. Treatment was for 2 h. The results of duplicate experiments, which agreed to ±15%, were averaged. The highest point for β-actin was assigned a relative value of 5.

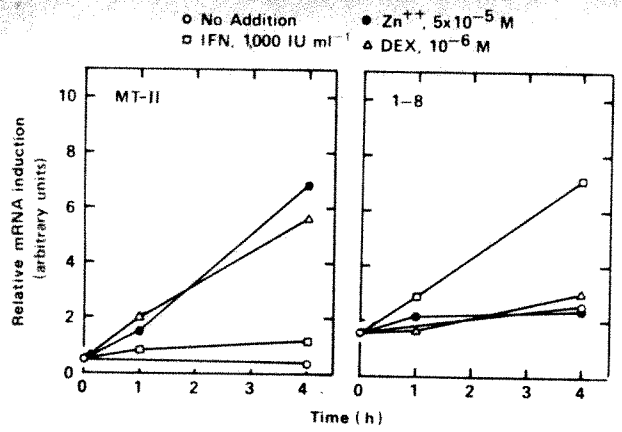

Fig. 3 Effects of IFN-α, dexamethasone and Zn^{2+} on accumulation of *MT2* mRNAs. Levels of mRNA were measured by the slot hybridization technique described previously[3]. One experiment is shown, but similar results were obtained in two additional independent experiments. The increase in *MT2* mRNA after 4 h was 3–5-fold for IFN-α, consistent with the results reported previously[3] and 15–20-fold for Zn^{2+} or dexamethasone. Rabbit β-globin mRNA was added to the lysis buffer to allow correction for differences in RNA recovery to be made. Levels of endogenous β-actin mRNA were also measured. The β-actin and β-globin mRNA levels did not vary significantly with any of the treatments used.

Pretreatment with cycloheximide did not block interferon-induced transcription of the *MT2* or *HLA* genes (Fig. 2*a*), in agreement with our previous result[3] for *1-8*. Cycloheximide alone had little effect on the transcription of these genes, but greatly increased transcription of the β-actin gene, as reported previously[3,11].

The increased transcription of *MT2* after treatment with IFN-α (Fig. 2*a*) shows that control of the *MT2* promoter is more complex than believed previously[8]. To define regulation of *MT2* expression more precisely, we measured mRNA levels and transcription rates following exposure of the cells to IFN-α, dexamethasone no Zn^{2+}; we found that either IFN-α or dexamethasone induced a 3–4-fold increase in the transcription rate of *MT2* (Fig. 2*a*,*b*) while treatment with 50 μM Zn^{2+} produced a 13-fold increase (Fig. 2*b*).

The rate of *MT2* mRNA accumulation was linear for 4 h after treatment with IFN-α, dexamethasone or Zn^{2+} (Fig. 3). We have shown previously[3] that the induction of *MT2* mRNA by interferon is maximal after 12 h. In control experiments, neither dexamethasone nor Zn^{2+} stimulated accumulation of *1-8* mRNA (Fig. 3). Although IFN-α or dexamethasone produced similar increases in *MT2* transcription (Fig. 2*b*), the accumulation of *MT2* mRNA was much greater with dexamethasone (Fig. 3). Treatment with Zn^{2+} increased gene transcription much more than did dexamethasone treatment (Fig. 2*b*), but the rates at which the mRNAs accumulated were very similar (Fig. 3). We conclude that post-transcriptional stabilization and increased transcription both contribute significantly to accumulation of *MT2* mRNA in dexamethasone-treated T98G cells. This effect is selective, because treatment with dexamethasone does not lead to an increase in *1-8* or β-actin mRNA.

Yoshie *et al.*[12] transfected Ltk$^-$ cells with fragments of an *HLA* gene lacking not only the 5′-flanking sequences but also all of the first and part of the second exon. Nevertheless, RNAs corresponding to the fragments were induced on treatment with 1,000 IU ml^{-1} of IFN-α. As shown in Figs 1 and 2, IFN-α induces transcription of class I *HLA* genes, so it is possible that signals for interferon-induced transcription are preserved in the gene fragments of Yoshie *et al.*[12]. However, we have shown previously that post-transcriptional events can contribute to accumulation of the interferon-induced *1-8* mRNA[3]. Therefore, it seems more likely that the results of Yoshie *et al.*[12] are explained by interferon-induced post-transcriptional changes and that the transcription rates of the deleted, transfected *HLA* gene fragments do not change when interferon is added.

Fig. 4 Homologous 5′ sequences flanking the *MT2* and *HLA* genes. Bold face letters indicate nucleotides conserved in at least three of the four examples. N, any nucleotide. The sequences are from Malissen *et al.*[16], Karin and Richards[24] (with one modification, provided by Dr Michael Karin, personal communication), Das *et al.*[17] and Strachan *et al.*[15] Access to the QUEST, SEQ and IFIND programs was generously provided by IntelliGenetics, a division of IntelliCorp. QUEST was used to retrieve sequences from the NIH and EMBL databases. SEQ was used to find initial intra- and intersequence homologies, for probability calculations and for symmetry searches. The default SEQ parameters were used except for Loopout, which was set to 1. IFIND, based on the algorithm of Wilbur and Lipman[25], was used to make the final alignments, to arrive at a consensus sequence, and to search the NIH and EMBL databases for homologies to the consensus sequence.

Our conclusion that post-transcriptional events are significantly involved in the accumulation of *MT2* mRNA after dexamethasone treatment is similar to that of Vannice *et al.*[13], who showed that dexamethasone produces a marked accumulation of the mRNA for α_1-acid glycoprotein, but no increase in transcription. We suggest a refinement of the idea of Richards *et al.*[14] that differences in sequences 5′ to *MT2* genes account for their differential regulation. Sequences responsible for post-transcriptional regulation are probably also involved.

Because IFN-α regulates transcription of the *MT2* and *HLA* genes, we compared the sequences upstream from *MT2* with sequences upstream from the three *HLA* genes for which such information is available—a class I *HLA-A3* gene[15], an unidentified class I gene[16] and a class II *HLA-DR*α gene[17]. Class I genes are efficiently induced by both IFN-α and IFN-γ, whereas the *HLA-DR*α gene is efficiently induced by IFN-γ and poorly induced by IFN-α[5]. The cap sites for *HLA-A3* and the gene of Malissen *et al.*[16] have not been mapped. By analogy to the *HLA-DR* sequence, we tentatively assign the CAT (CCAAT) and TATA (TCTAAA) boxes to positions 162 and 188 in the *HLA-A3* sequence and to positions 156 and 182 in the sequence of Malissen *et al.*[16].

The two *HLA* class I sequences share considerable homology upstream of their 5′ start sites. There is also homology between a region about 760 bp 5′ to the start site of the *MT2A* gene and a region about 250 bp 5′ to the putative start site in the sequence of Malissen *et al.*[16] (Fig. 4). As calculated with the SEQ program, the probability of finding such a homology by chance is 0.018, taking the base compositions into account. A similar region of homology was also found for *HLA-A3* and *HLA-DR*α (Fig. 4). The only significant homology between sequences 5′ to the two *HLA* class I genes and the class II *HLA-DR*α gene was found in the region also homologous to *MT2*. Alignment reveals that AGTTTCTC$^{C}_{T}$TCTC, the core of the consensus sequence, is nearly invariant and that the first seven bases of this core are absolutely invariant. The consensus sequence lies 142 or 147 bp upstream of the TATA box of the class I gene of Malissen *et al.*[16] or the *HLA-A3* gene, respectively. It is 600 or 567 bp upstream of the *MT2* or *HLA-DR*α TATA box, respectively, and there is no dyad symmetry near any of the consensus sequences. We also compared the consensus sequence with all human and murine sequences in the databases of the National Institutes of Health (NIH) and the European Molecular Biology Laboratory (EMBL). Only the *HLA* and *MT* sequences used to derive the consensus showed significant homology to it, indicating that the consensus is not merely a sequence repeated frequently in genomic DNA.

The consensus sequence extends over 28 bp and is considerably longer than the sequences proposed to be involved in glucocorticoid-mediated induction of mouse mammary tumour

virus (TGGTACAAAATGTTCT) or *MT2* transcription[8,14], or in metal ion induction[8] of *MT2* ($^{TG}_{GT}$CGCCCGGC$^{T}_{C}$C). It is also more extensive than the consensus sequence for transcriptional regulation of heat shock genes (GTNGAANNTTCNAG) which has been shown to function in mammalian cells, *Xenopus* oocytes and *Drosophila*[18-20]. General regulation of yeast amino-acid biosynthesis also depends on a short regulatory sequence (A^{A}_{T}GTGACTC)[21,22]. The sequences involved in regulation of transcription by glucocorticoids, metal ions or heat shock are conserved among different species. We have found no homology between the consensus sequence shown in Fig. 4 and sequences 5′ of mouse *H-2* genes, but the mouse sequences available in the NIH and EMBL databases do not extend far beyond the 5′ start sites of the mRNAs.

Experiments are now under way to test directly the role of the consensus sequence in transcriptional regulation by interferon. If this sequence is involved, it may be long enough to be used to isolate genes directly from phage or cosmid libraries by hybridization, and would help in locating their regulatory regions. Both consensus and naturally occurring sequences might then be used to isolate the proteins responsible for interferon transcriptional regulation.

We thank Warren Liao for helpful discussions, James Darnell for communicating results before publication and Peter Gunning and Lawrence Kedes for the β-actin cDNA clone. This work was supported by PHS grant CA30124 from the National Cancer Institute. R.L.F. is a trainee of the NIH Medical Scientist Training Program.

Transient reversion of *ras* oncogene-induced cell transformation by antibodies specific for amino acid 12 of *ras* protein

J. R. Feramisco*, R. Clark†, G. Wong†, N. Arnheim†, R. Milley† & F. McCormick†

* Cold Spring Harbor Laboratory, Cold Spring Harbor, New York 11724, USA and † Department of Human Genetics, Cetus Corporation, 1400 53rd Street, Emeryville, California 94608, USA

The proteins encoded by the *ras* oncogene are thought to trigger expression of the transformed phenotype in some types of cancer cells. In human cells, the *ras* protein family consists of several members including normal (proto-oncogene) and mutant (oncogene) forms[1-3]. In general, the proto-oncogene forms are thought to be involved in the normal growth control of cells, while the mutant forms (which apparently result from somatic mutation of the normal *ras* genes) appear to be responsible, in part, for the loss of normal growth control. On microinjection into living normal cells, the purified *ras* oncogene protein (p21) induces a characteristic loss of growth control in cells within several hours[4,5]. The mutant forms of the different *ras* proteins typically contain a single amino-acid change, usually at position 12 or less frequently at position 61 (ref. 6). Here we report that microinjection of antibodies specific for amino acid 12 of the oncogenic v-Ki-*ras* protein into cells transformed by this protein causes a transient reversion of the cells to a normal phenotype. The fact that this antibody inhibits binding of GTP to the v-Ki-*ras* protein supports the notion that GTP binding is essential to the transforming function of this oncogene product.

The role of *ras* proteins in cellular metabolism is not yet understood, but it is known that they are localized on the inner surface of the plasma membrane and bind GTP and GDP[7,8]. Recent analysis of the normal and mutant forms of the human Ha-*ras* proteins purified from bacterial expression systems[9,10] or present in the bacterial lysates after expression[11] has shown that *ras* proteins are able to hydrolyse GTP to GDP. It has been

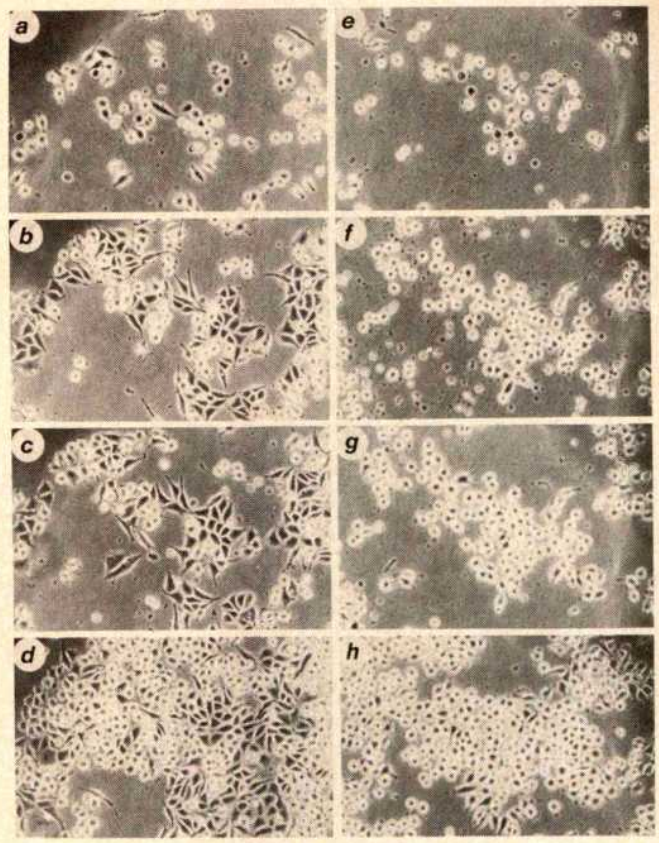

Fig. 1 Morphology of Ki-NRK cells after microinjection of anti-p21-Ser and control IgG. Approximately 35 Ki-NRK cells (growing in 10% fetal calf serum in Dulbecco's modified Eagle's medium) in each of the two test areas (marked by ink circles under the dish) were microinjected with anti-p21-Ser (*a-d*) or non-immune IgG (*e-h*) as described elsewhere[18]. Phase-contrast photomicrographs were taken of the two areas 30 min (*a, e*), 24 h (*b, f*), 36 h (*c, g*) and 48 h (*d, h*) after injection. Note that the cells injected with anti-p21-Ser show a normal flattened morphology for some time and grow at a slower rate than either the surrounding uninjected cells or the cells injected with the control IgG. ×4.

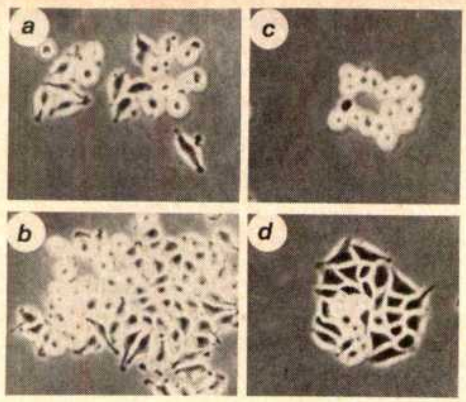

Fig. 2 Slower growth rate of Ki-NRK cells after microinjection of anti-p21-Ser antibody. Two areas of sparsely plated Ki-NRK cells growing on a dish (see Fig. 1 legend) were injected with either control IgG (*a*) or anti-p21-Ser IgG (*c*). The two areas were photographed immediately after injection (*a* and *c*) and 24 h later (*b* and *d*, respectively). Note the different rates of growth between the two areas of cells.

suggested that *ras* proteins function in a manner analogous to the 'G' regulatory protein of the adenylate cyclase system[4,9–13], which is also localized in the plasma membrane; this model is particularly attractive because G proteins activate adenylate cyclase through a GTP-dependent reaction, and inactivate the enzyme through hydrolysis of bound GTP to GDP and P_i. Position 12 mutants of human Ha-*ras* protein show a 10-fold reduction in rate of GTP hydrolysis[9–11], and may therefore represent abnormally activated regulatory proteins.

To obtain a biochemical probe capable of distinguishing between the normal and oncogenic forms of the *ras* proteins, antibodies were raised against *ras* (p21)-related peptides that differed at position 12. One antibody, designated anti-p21-Ser, was affinity-purified from the serum of rabbits immunized with the peptide ^{6}Lys-Leu-Val-Val-Gly-Ala-Ser-Gly-Val-Gly-Lys Cys-^{18}Ser (Ser at position 12) coupled covalently to carrier protein (R.C., G.W., D. Nitecki and F. McC., unpublished). Anti-p21-Ser was found to bind the v-Ki-*ras* protein (serine at position 12) but neither the v-Ha-*ras* protein (arginine at position 12) nor the *ras* protein containing glycine (normal) at position 12. In addition, biochemical studies showed that this antibody blocked both the GTP-dependent autophosphorylation and GTP-binding activities of the v-Ki-*ras* protein, suggesting that the antibody and GTP bind to the same region of the protein.

Given this high degree of specificity of the affinity-purified antibody preparation for the oncogenic v-Ki-*ras* protein, as well as the ability of the antibody to inhibit the GTP binding activity of the v-Ki-*ras* protein, it seemed possible that introduction of this antibody preparation into living, transformed cells might block the biochemical action of the *ras* oncogene protein *in vivo*, without affecting the function of the proto-oncogene product. Using microneedle injection procedures, $\sim 5 \times 10^5$ molecules of purified IgG (either anti-p21-Ser or non-immune serum) were injected into the cytoplasm of NRK cells transformed by the v-Ki-*ras* oncogene (called Ki-NRK cells); this represents a 5–10-fold excess of antibody over the estimated amount of *ras* protein in these cells[4]. Within 15 h and persisting for 48 h after injection of the anti-p21-Ser antibodies, the Ki-NRK cells showed a flattened, normal morphology (Fig. 1*a–d*); after 48 h, the cells reverted to their rounded morphology. In contrast, cells on the same dish which had been injected with control IgG showed no obvious change in morphology (Fig. 1*e–h*). (Control IgGs included goat anti-mouse IgG and rabbit non-immune IgG.) Inspection of the photographs taken for these experiments indicated that in addition to the reversion of the transformed phenotype, the flattened cells appeared to grow at a slower rate than either cells injected with control IgG or surrounding uninjected cells; this is evident from Fig. 2, where cells injected with control IgG have tripled in number over 24 h post-injection while cells injected with the anti-p21-Ser IgG have only doubled in number over the same time period. Based on data from the genetic analysis of the yeast *ras* genes which indicated that complete elimination of *ras* gene expression yielded non-viable cells[14,15], we might predict that antibodies that block the function of both the normal and oncogenic forms of the *ras* proteins would kill or prevent growth of microinjected transformed mammalian cells. Figures 1 and 2 show, however, that the cells injected with anti-p21-Ser are indeed able to grow, a result in agreement with biochemical experiments which showed that this antibody binds only to the oncogenic form of the *ras* protein with serine at position 12 (R.C., G.W., N.A., D. Nitecki and F.McC., unpublished).

By using immunofluorescence microscopy, we were able to determine exactly which cells had been injected with the two antibody preparations. Those cells that had been injected with

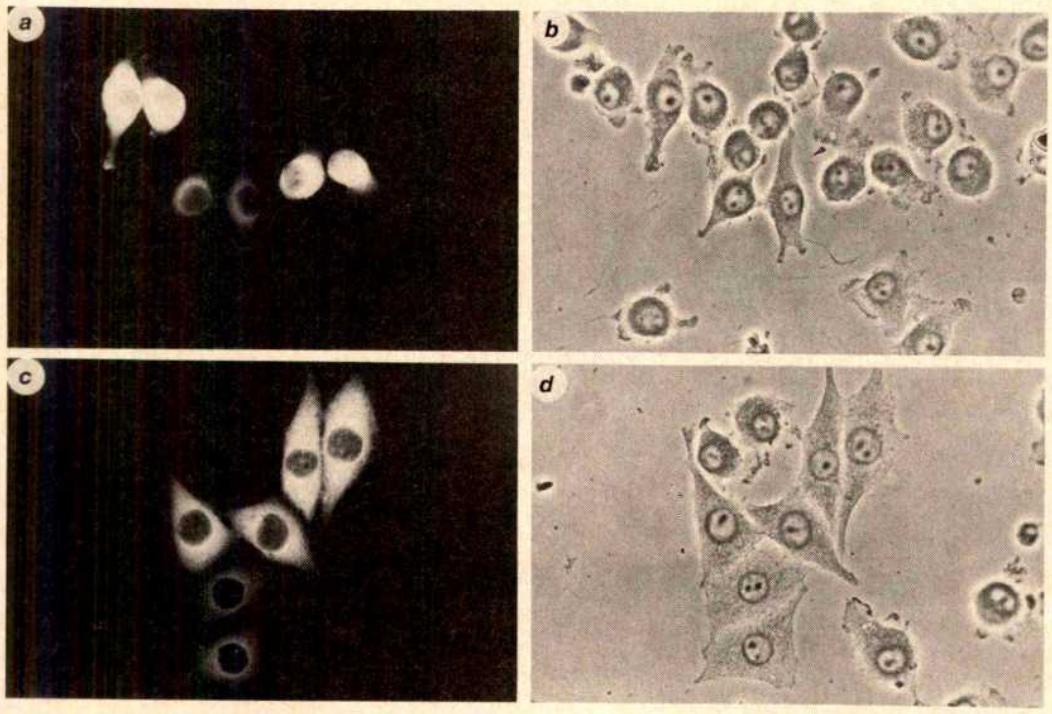

Fig. 3 Correspondence of the flattened appearance of Ki-NRK cells with microinjection of anti-p21-Ser antibodies. Ki-NRK cells (growing on glass coverslips) were injected with non-immune IgG (*a*, *b*) or anti-p21-Ser (*c*, *d*) and fixed (absolute methanol, −20 °C, 5 min) 24 h after injection. The cells were treated with fluorescein isothiocyanate-labelled goat anti-rabbit IgG (Cappel Laboratories), which stained only the injected cells. The fields of cells were photographed by epifluorescence (*a*, *c*) and phase-contrast (*b*, *d*) microscopy with a Zeiss Photomicroscope III as described elsewhere[18]. *a*, *b* Represent the same field of cells injected with control IgG and *c* and *d* the same field of cells injected with anti-p21-Ser.

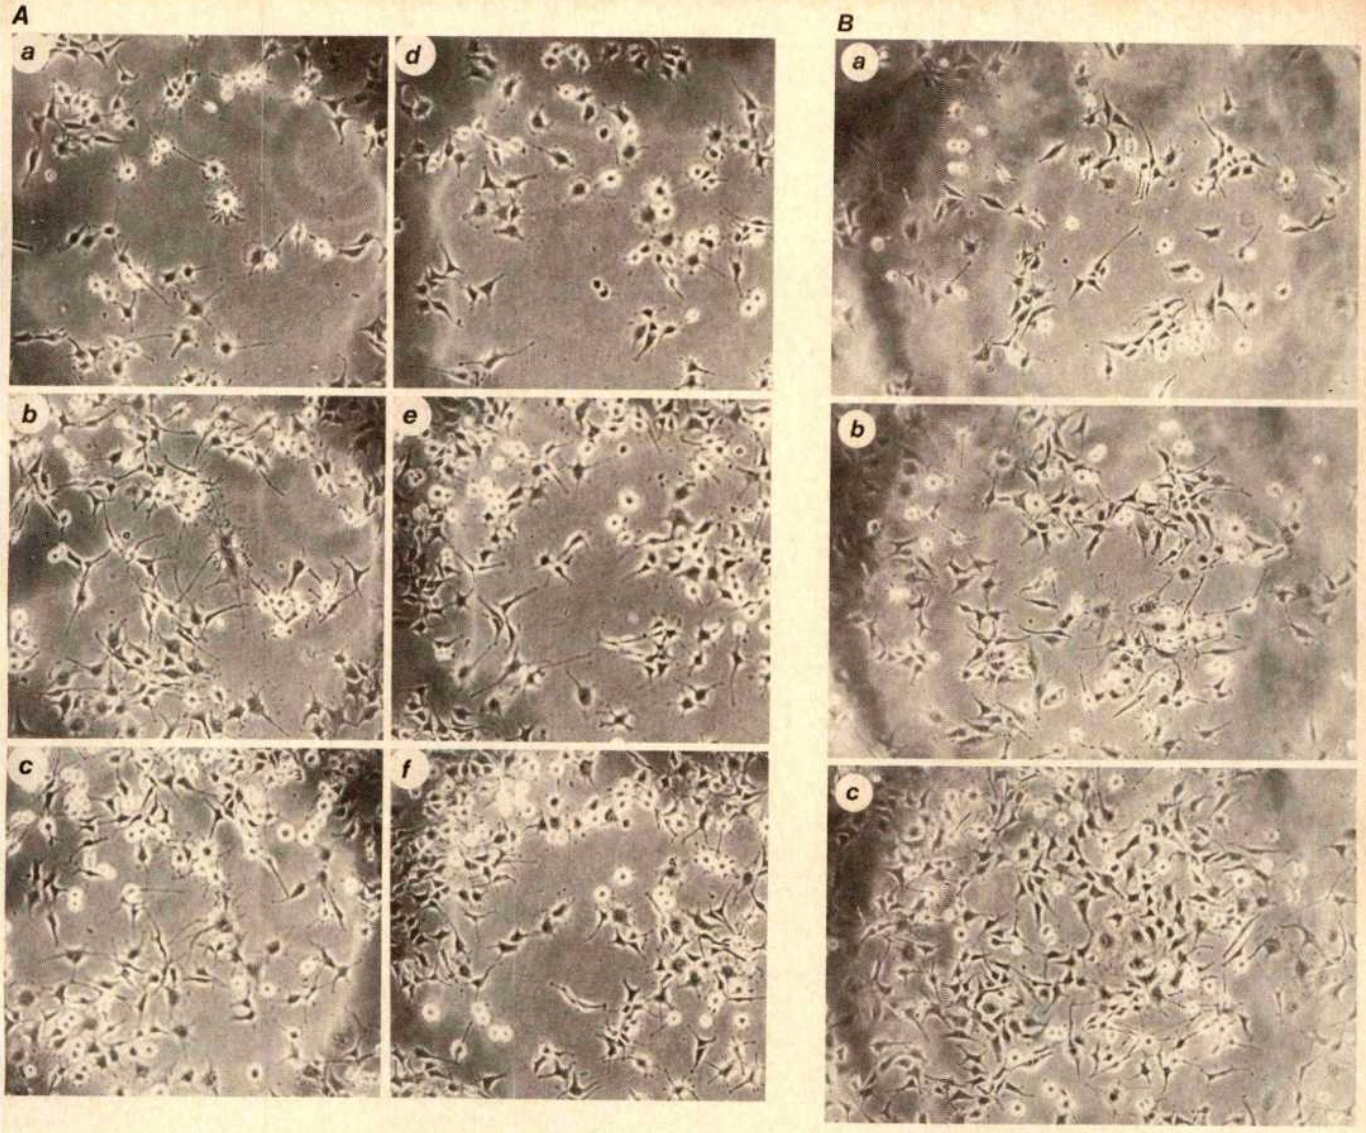

Fig. 4 Morphology of Ha-NRK cells after microinjection of: *A*, anti-p21-Ser and control IgG; and *B*, monoclonal antibody Y-238. *A*, Approximately 25 Ha-NRK cells in defined areas (marked by ink circles on the bottom of the dish) were injected with anti-p21-Ser (*a–c*) or non-immune IgG (*d–f*). The areas were photographed 30 min (*a*, *b*), 24 h (*c*, *d*) and 36 h (*e*, *f*) post-injection. No change in morphology or growth rate was observed for either antibody. *B*, Approximately 30 Ha-NRK cells were injected with monoclonal antibody Y-238 (ref. 16) and photographed 30 min (*a*), 24 h (*b*), and 36 h (*c*) after injection. Note the lack of effect of this monoclonal antibody on either the morphology or the growth rate of the cells.

anti-p21-Ser had the morphologically normal, flattened appearance (Fig. 3*c*, *d*) whereas cells injected with control IgG retained their rounded, transformed appearance (Fig. 3*a*, *b*).

To determine the specificity of the *in vivo* effect of the anti-p21-Ser preparation in terms of cells transformed by other oncogenic *ras* proteins, the anti-p21-Ser and control IgGs were injected (5×10^5 molecules per cell) into Ha-NRK cells (that is, NRK cells transformed by the v-Ha-*ras* oncogene protein, which has an arginine at position 12). Photomicroscopy indicated that neither antibody had an effect on these cells (Fig. 4*A*); this result is consistent with the observation that, *in vitro*, the anti-p21-Ser preparation does not react with the v-Ha-*ras* protein (R.C., G.W., N.A., D. Nitecki and F.McC., unpublished).

To determine whether the ability of anti-p21-Ser to induce reversion to normal phenotype is a general property of anti-p21 antibodies, one other antibody was tested by this assay. Furth and co-workers have produced several rat-derived monoclonal antibodies against the v-Ha-*ras* protein[16], including one that is relatively specific for the Ha-*ras* proteins (called Y-238); this antibody does not block GTP binding activity, does not discriminate between normal and mutant forms of the *ras* protein and probably binds to a site in the Ha-*ras* protein that is not influenced by amino acid 12 of the protein. Y-238 was microinjected into Ha-NRK cells (1×10^6 molecules per cell), and the cells were examined by photomicroscopy for 48 h. Neither the Y-238 monoclonal antibody nor a control IgG preparation had any effect on the morphology or growth rate of the cells (Fig. 4*B*); similar results were obtained using Y-259 anti-p21 antibody. Thus, the antibody either binds to a non-essential site on the *ras* protein or does not bind at all to the *ras* protein in these cells.

These results, together with the ability of anti-p21-Ser to block GTP binding by p21 *in vitro* (R.C., G.W., N.A., D. Nitecki and F.McC., unpublished), are consistent with the idea that the interaction of p21 with GTP is crucial to the transforming function of the *ras* gene. However, further studies are required to examine the possibility that the antibody disrupts other important activities of p21 such as membrane localization or interactions with cellular proteins. Whatever mechanism is responsible for the observed effects of the microinjected anti-p21-Ser on cell behaviour, the data presented here indicate that antibodies capable of inactivating oncogene but not proto-oncogene products can block the expression of the transformed phenotype in living cells. Gallick *et al.*, using antibodies directed against the $p37^{mos}$ oncogene product of the Moloney murine sarcoma virus, reached a similar conclusion; microinjection of the antibodies yielded at least a different morphology in transformed cells[17].

When antibodies specific for other single mutations in the *ras* protein family (N.A. *et al.*, in preparation) become available, we will be able to extend this approach to inhibition of the function of the other forms of the oncogenic *ras* proteins in living cell and biochemical systems. Such experiments, coupled with studies in which the human *ras* oncogene protein is injected into normal cells, resulting in transient proliferation[4,5], provide new ways of examining the physiology and cell biochemistry of the transformation process.

We thank J. D. Watson for his support, and Drs D. Bar-Sagi, N. Sullivan, W. Welch and M. Wigler for helpful discussions. We thank Dr Mark Furth of the Memorial Sloan-Kettering Cancer Center for his gift of monoclonal antibodies against the *ras* protein (Y-238 and Y-259), and acknowledge the technical assistance of N. Kronenberg, C. Hallaran, P. Renna and M. Szadkowski. This work was supported in part by NIH grant GM28277 (to J.R.F.).

The recent development of molecular cloning systems in *Streptomyces*[1–4] has made possible the isolation of biosynthetic genes for some of the many antibiotics produced by members of this important genus of bacteria[5–10]. Such clones can now be used to test the idea that novel antibiotics could arise through the transfer of biosynthetic genes between streptomycetes producing different antibiotics[11]. The likelihood of a 'hybrid' compound being produced must depend on the substrate specificities of the biosynthetic enzymes, about which little is known. In attempts to demonstrate hybrid antibiotic production, we therefore began with strains producing different members of the same chemical class of compounds in order to maximize the chance of success. Here we report the production of novel compounds by gene transfer between strains producing the isochromanequinone antibiotics actinorhodin[12], granaticin[13] and medermycin[14]. These experiments were made possible by the recent cloning of the whole set of genes for the biosynthetic pathway of actinorhodin from *Streptomyces coelicolor* A3(2) (ref. 8). We believe that this represents the first report of the production of hybrid antibiotics by genetic engineering.

‖ Present address: Glaxo Group Research, Greenford, Middlesex UB6 0HE, UK.

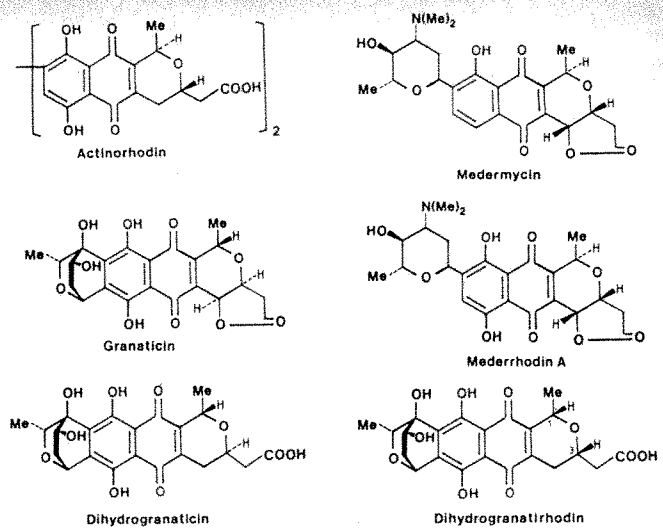

Fig. 1 Structures of the isochromanequinone antibiotics. The absolute stereochemistry of dihydrogranatirhodin is tentative (see text).

Plasmid pIJ2303 (ref. 8) consists of the low-copy-number vector plasmid pIJ922, derived from SCP2* (ref. 15), with 32.5 kilobases (kb) of *S. coelicolor* A3(2) DNA inserted at its unique *Bam*HI site[8]. That this inserted DNA carries the complete cluster of genes (*act*) for the biosynthesis of actinorhodin (Fig. 1) from simple primary metabolites (probably acetate) is shown by complementation of all available classes of *S. coelicolor act* mutants by pIJ2303 and by the production of actinorhodin by several species of *Streptomyces* (including *S. parvulus* ATCC 12434, *S. peucetius* ATCC 29050, *S. tanashiensis* KA-415 and *S. glaucescens* ETH 22794) carrying pIJ2303 (F.M., H.M.K. and D.A.H., unpublished).

In an analysis of the organization and expression of the *act* genes, segments of the total *act* DNA of pIJ2303 have recently been inserted (F.M., unpublished) into the *Bam*HI site of pIJ922 or into the *Bam*HI, *Bgl*II or *Pst*I sites of pIJ940 (a second low-copy-number vector derived from SCP2*; ref. 15). Some of these subclones, carrying different transcription units of the *act* region, were introduced by transformation into *Streptomyces* sp. AM-7161 (the producer of medermycin), *Streptomyces violaceoruber* Tü22 (the producer of granaticin), and a mutant (B1140) of Tü22 blocked in granaticin synthesis, by selecting for the thiostrepton-resistance marker of the vectors. The efficiency of transformation of these cultures, using standard conditions developed for *Streptomyces lividans* and *S. coelicolor*[16], by DNA of the clones (isolated from *S. coelicolor* A3(2) derivatives) was only 1–10 per μg of plasmid DNA, compared with 10^6–10^7 in *S. coelicolor* A3(2) (ref. 8). These reduced frequencies may reflect the operation of restriction systems, as well as the fact that no attempt was made to optimize transformation conditions for these strains. Nevertheless, transformants were obtained in all of the combinations attempted (Table 1).

Actinorhodin, granaticin and medermycin are all acid–base indicators which confer characteristic colours on the cultures producing them: red↔blue for actinorhodin; red↔purple for granaticin; and yellow↔brown for medermycin. It was apparent from the colours of AM-7161 and B1140 carrying pIJ2303 that the *S. coelicolor act* genes were being expressed in the recipient strains, as blue pigments were present in alkaline conditions. More strikingly, the colours of the cultures produced by introducing certain of the partial *act* clones into the medermycin producer (AM-7161) indicated that one or more novel compounds were present. Notable was the bright purple colour, at

Table 1 Antibiotics produced by the *Streptomyces* strains

Strain	Colour of culture‡		Relevant compounds identified†
	Acidic	Alkaline	
S. coelicolor A3(2)	Red	Blue	Actinorhodin
Streptomyces sp. AM-7161	Yellow	Brown	Medermycin
AM-7161/pIJ2303*	Red	Blue	Medermycin, actinorhodin
AM-7161/pIJ2301*	Red	Purple	Mederrhodin A, medermycin
AM-7161/pIJ2304	Yellow	Brown	Medermycin
AM-7161/pIJ2308	Yellow	Brown	NT
AM-7161/pIJ2312	Yellow	Brown	NT
AM-7161/pIJ2315*	Red	Purple	Mederrhodin A, mederrhodin B, medermycin

B1140/pIJ2314	Yellow	Brown	NT

* Plasmid DNA from these cultures was shown to be indistinguishable in structure from the same plasmid originally isolated in *S. coelicolor*, as judged by *Bam*HI digestion.

† To characterize the pigments present in AM-7161 carrying various clones, cultures were grown in liquid medium (seed stage: 2% glucose, 0.3% peptone, 0.3% beef extract, 0.1% yeast extract, 0.3% NaCl, 0.1% $CaCO_3$, *p*H 7.0, for 48 h at 28 °C; production stage: 1.5% glycerol, 1% soybean meal, 0.3% NaCl, *p*H 7.0, with shaking for 96 h at 28 °C, after addition of a 10% inoculum from the seed stage). The broth was adjusted to *p*H 7.0 with 1 M HCl and extracted with chloroform. After concentration of the extracts, they were analysed by silica-gel TLC run in chloroform/methanol (5:1). The pigments produced by cultures of Tü22 carrying pIJ2303, and B1140 carrying pIJ2303 and pIJ2308, were obtained from fermentations in a medium containing 1% raw ground peanuts, 1% glucose, 0.5% NaCl, 0.35% $CaCO_3$, 70 mg l^{-1} histidine, 10 mg l^{-1} guanine, 15 mg l^{-1} thiostrepton in baffled flasks shaken at 300 r.p.m. at 28 °C. Seed cultures were grown for 24 h and production cultures for 48 h (granaticin-related pigments) or 144 h (actinorhodin) after addition of 5% inoculum. The broth was then adjusted to *p*H 2.0 and the culture was filtered. The residue was resuspended in 1 M NaOH and re-filtered. After adjusting the *p*H of the filtrate to 2.0, the precipitated crude pigments were collected by centrifugation and dried under vacuum. TLC analyses were done on oxalic acid-impregnated silica gel (chloroform/ethyl acetate, 6:4).

‡ Cultures were grown on R2YE plates[16] (containing histidine and guanine in the case of B1140, which carries two auxotrophic mutations); after 4–5 days they were exposed to the fumes of either concentrated HCl or ammonia solution. NT, not tested.

alkaline *p*H, of the culture carrying pIJ2315; cultures carrying pIJ2301 and pIJ2316 had a duller purple colour. B1140 carrying pIJ2308 had a colour resembling that of granaticin, and this result also demonstrated a 'cooperation' between gene products in the actinorhodin and granaticin pathways.

We characterized the pigments present in AM-7161 carrying various clones. The results (Table 1) confirmed that AM-7161 carrying pIJ2315 produced, in addition to medermycin, large amounts of a novel compound; this material was also present, in smaller quantities, in AM-7161 carrying pIJ2301 and pIJ2316, and was termed 'mederrhodin A'. A second novel compound ('mederrhodin B') was present in the aqueous phase after chloroform extraction of the AM-7161/pIJ2315 broth. Interestingly, AM-7161 carrying pIJ2303 produced abundant actinorhodin, together with medermycin, but no novel compounds were detected.

Mederrhodin A was purified by passing the acidified broth of AM-7161/pIJ2315 through a Diaion HP-20 column (Mitsubishi) to adsorb medermycin and related compounds. The column was washed with deionized water and the pigments were eluted with 70% aqueous acetone. After evaporation of the acetone from appropriate fractions, the concentrate was adjusted to *p*H 7.0 with 1M NaOH and extracted twice with equal volumes of chloroform. Mederrhodin A was then purified by preparative TLC. Structural determination of field desorption-mass spectroscopy and element analysis revealed hydroxymedermycin, and the position of the hydroxyl group was determined by ultraviolet and ^{1}H-NMR spectroscopy (Fig. 1). Mederrhodin A, like medermycin, was found to have antibiotic activity against various Gram-positive bacteria.

The pigments produced by cultures of Tü22 carrying pIJ2303, and B1140 carrying pIJ2303 and pIJ2308, were obtained as described in Table 1. B1140/pIJ2303 and B1140/pIJ2308 produced a mixture of granaticin and dihydrogranaticin (Fig. 1), pigments characteristic of the Tü22 strain; actinorhodin was also present in B1140/pIJ2303, but no novel compounds were detected. However, Tü22 carrying pIJ2303 produced, in addition to actinorhodin, a novel compound related to dihydrogranaticin; this compound was named 'dihydrogranatirhodin'. Interestingly, very little granaticin or dihydrogranaticin was present.

Dihydrogranatirhodin was purified by column chromatography on oxalic acid-treated silica gel (chloroform) and preparative TLC, and was converted to the methyl ester as described for dihydrogranaticin[17]. The mass spectrum gave the molecular formula $C_{23}H_{24}O_{10}$ and the ultraviolet/visible spectrum indicated the presence of the same 5,8-dihydroxy-1,4-naphthoquinone chromophore as in dihydrogranaticin. The ^{1}H-NMR spectrum closely resembles that of dihydrogranaticin, but shows up-field shifts of the signals for H-3 and H-1, as has been seen in synthetic model compounds with *cis*-arrangement of these two hydrogens[17]. This was confirmed by observation of a nuclear Overhauser enhancement of 5.5% for H-3 on irradiation of H-1. Hence, dihydrogranatirhodin is either the C-3 or the C-1 epimer of dihydrogranaticin. As the configuration at C-3 in actinorhodin is determined early in the biosynthesis by reduction of the C-3 carbonyl group (X.G.He, S. P. Cole and H.G.F., unpublished), we suggest that dihydrogranatirhodin has the actinorhodin (3S) configuration at C-3 and the granaticin (1S) configuration at C-1 (Fig. 1).

The demonstration of novel compounds in hybrid strains prepared by transferring actinorhodin genes into both the granaticin- and the medermycin-producer augurs well for the widespread usefulness of genetic engineering as a new tool in antibiotic discovery. There seems little doubt that dihydrogranatirhodin and the mederrhodins are indeed the products of 'hybrid' biosynthetic pathways arising through an interaction

between enzymes encoded by structural genes originating from two different streptomycetes, rather than the results of the activation of latent genetic information in the recipient strains. (The latter mechanism is the most probable explanation for the three reports of the discovery of novel compounds through natural inter-strain matings (refs 18–20; discussed in ref. 21).) The evidence is most compelling for mederrhodin A, since, of the clones tested, pIJ2301, pIJ2315 and pIJ2316 (which led to mederrhodin A synthesis by AM-7161) all contain a complete transcription unit (absent from pIJ2304, pIJ2308, pIJ2312 and pIJ2317) which complements class V *act* mutants of *S. coelicolor* (F.M., unpublished); such mutants have recently been shown to be blocked in the corresponding hydroxylation involved in actinorhodin biosynthesis (S. P. Cole and H.G.F., unpublished). A true metabolic cooperation between the actinorhodin and granaticin biosynthetic enzymes is indicated also by complementation of the B1140 mutant by pIJ2308, but not by the other clones tested. B1140 can act as a secretor in co-synthesis tests with *S. coelicolor act* mutants of classes I, III and VII, but not of classes IV, V and VI[22], suggesting that its block is equivalent to that of class IV *act* mutants. Significantly, pIJ2308 is the only clone tested that carries a complete transcription unit for the class IV *act* gene (F.M., unpublished). Moreover, the 'mixed' stereochemistry found in dihydrogranatirhodin has not previously been encountered in any isochromanequinone antibiotic, even though a strain of *Streptomyces roseofulvus* has recently been found to produce both frenolicin B (with the same configuration of the pyranoid ring as actinorhodin) and nanaomycins A and βA [with the same configuration as granaticin (S.Ō. *et al.*, unpublished)].

The different results obtained with AM-7161 and Tü22 carrying the complete set of actinorhodin biosynthetic genes is interesting. In AM-7161, the donor and recipient gene sets appear to operate independently, with production of the two parental antibiotics but no novel compounds. Only when a partial *act* clone was introduced into the medermycin-producer was a hybrid product formed. In contrast, Tü22 carrying pIJ2303 produced dihydrogranatirhodin (as well as some actinorhodin), to the almost total exclusion of the normal antibiotics of the recipient. This differing behaviour may reflect several factors, including the relative specificities and affinities of the biosynthetic enzymes for their substrates, the regulation of gene expression and any possible 'channelling' of precursors within individual biosynthetic pathways. Such considerations must be borne in mind in the future use of genetic engineering in antibiotic discovery, or in attempts to modify existing antibiotics in predetermined ways.

Molecular cloning of Ancient Egyptian mummy DNA

Svante Pääbo

Department of Cell Research, The Wallenberg Laboratory, University of Uppsala, Box 562, S-75122 Uppsala, Sweden and Institute of Egyptology, Gustavianum, University of Uppsala, S-75120 Uppsala, Sweden

Artificial mummification was practised in Egypt from ~2600 BC until the fourth century AD. Because of the dry Egyptian climate, however, there are also many natural mummies preserved from earlier as well as later times. To elucidate whether this unique source of ancient human remains can be used for molecular genetic analyses, 23 mummies were investigated for DNA content. One 2,400-yr-old mummy of a child was found to contain DNA that could be molecularly cloned in a plasmid vector. I report here that one such clone contains two members of the *Alu* family of human repetitive DNA sequences, as detected by DNA hybridizations and nucleotide sequencing. These analyses show that substantial pieces of mummy DNA (3.4 kilobases) can be cloned and that the DNA fragments seem to contain little or no modifications introduced postmortem.

Samples were removed from 23 different mummies and mummy fragments. These specimens varied in age from the Sixth Dynasty (~2370–2160 BC) to late Roman times. Whenever possible, representative samples were taken from all the different tissues that could be identified visually. After rehydration and preparation of microscopical sections[1], the samples were studied using conventional histological stains as well as staining by ethidium bromide, which allows detection of small amounts of DNA. The cartilage cells from the outer ear of a mummified female head (Egyptian Museum, Berlin, GDR) as well as cells in the epidermis and subcutaneous tissues of a male head (Viktoria Museum, Uppsala; inventory number VM3251) proved to contain identifiable cell nuclei stainable by ethidium bromide. When the DNA from the latter sample was extracted, however, it was found to contain modified pyrimidines[2,3] and was intractable to molecular cloning. In contrast, cells of the epidermis and several subcutaneous structures from a less than 1-yr-old boy from the collections of the Egyptian Museum,

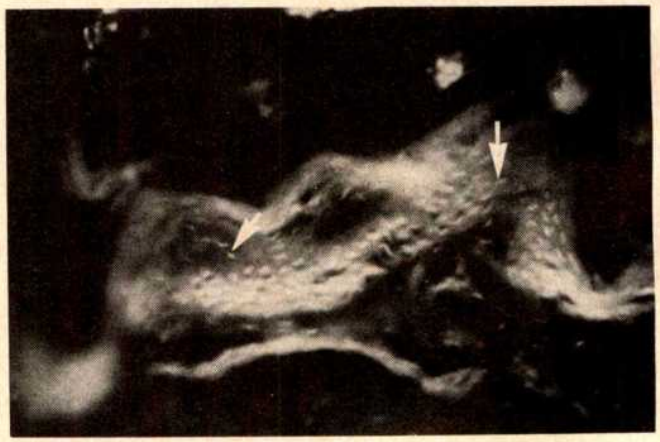

Fig. 1 Tissue section of skin from the left lower leg of the Berlin mummy used for molecular DNA cloning. Ethidium bromide staining allows the visualization of nucleic acids in the cell nuclei (arrows).
Methods. Small tissue samples were rehydrated in an aqueous solution of 1% Na_2CO_3 (w/v), 0.5% formalin and 28.5% ethanol[1] for 48 h. Paraffin embedding and sectioning were performed using routine protocols. After deparaffination, the sections were stained in a 5 $\mu g\ ml^{-1}$ solution of ethidium bromide in phosphate-buffered saline (PBS) for 30 min, followed by extensive washing in PBS and inspection under a Leitz fluorescence microscope. ×180.

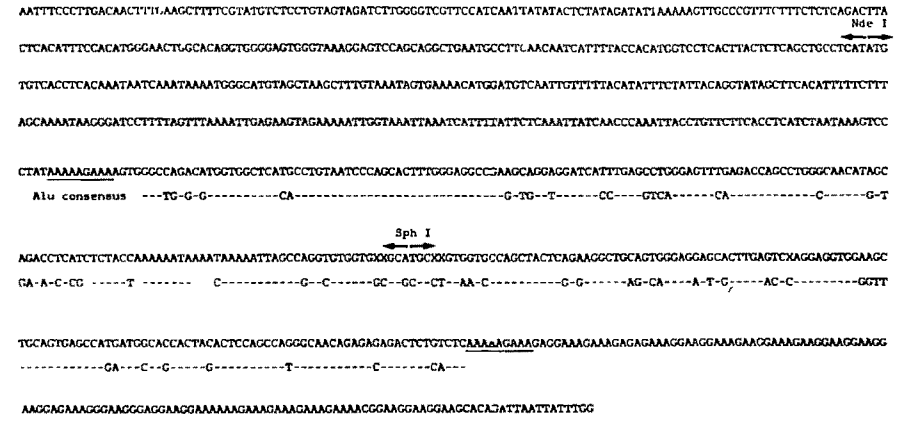

Fig. 2 DNA sequence of part of the mummy clone pMUM2:9. The 9-bp direct repeats flanking the *Alu* sequence are underlined. In the *Alu* consensus sequence[8] only nucleotides differing from the pMUM2:9 sequence are specified

Methods. DNA was prepared from 1.6 g mummy tissue, essentially according to the protocol described previously[5]. The DNA was made blunt-ended with *Escherichia coli* DNA polymerase (Klenow fragment) (Pharmacia P-L Biochemicals) according to the manufacturer's instructions and in the presence of trace amounts of radioactively labelled nucleotides The sample was then size-fractionated by gel filtration on a G-50 column (Pharmacia, Uppsala) Excluded fractions were pooled and ethanol-precipitated and 25 ng of this material cloned in a *Sma*I-digested and alkaline phosphatase-treated pUC8 plasmid[6]. Then, 700 of the white clones were transferred to nitrocellulose filters and screened[20] with a nick-translated[7] 550-bp *Bgl*II/*Sph*I fragment from a HLA-DR pseudogene[21], which contains an *Alu* repeat. The strongly hybridizing clone pMUM2:9 was isolated and restriction-mapped. Two *Alu* repeats were identified by Southern hybridization[9]. One of the *Alu* repeats as well as 500 bp of flanking DNA were sequenced according to the Maxam and Gilbert procedure[22] after labelling of the *Sph*I and *Nde*I restriction sites indicated.

Berlin, GDR (inventory no. 721) were preserved excellently by the above-mentioned criteria (Fig. 1). The radiocarbon age of this mummy was determined to 2,430 ± 120 BP, by the technique of accelerator mass spectroscopy[4].

I removed 1.6 g dry tissue from superficial parts of the left lower leg of the mummy and extracted DNA using detergent and sodium perchlorate[5] followed by phenol extraction and ethanol precipitation. When analysed by agarose gel electrophoresis, most of the DNA was <500 base pairs (bp) long. A minor portion of the material, however, was clearly ≥5,000 bp long (data not shown). Next, 15% of the extracted material was blunt-ended with *Escherichia coli* DNA polymerase (Klenow fragment) in the presence of trace amounts of radioactively labelled nucleotides. After termination of the reaction, the sample was size-fractionated by gel filtration and fractions containing the larger DNA fragments pooled and precipitated with ethanol. Then, 0.5% of this DNA was cloned in the bacterial plasmid pUC8 (ref. 6) and ~1,000 clones were obtained, 700 of which were transferred to nitrocellulose filters. Replicas of these were screened by colony hybridization using a radioactively labelled probe[7] containing a member of the *Alu* family of repetitive human sequences. The *Alu* repeats are present in at least 300,000 copies per human genome[8]. One clone (pMUM2:9), with an insert of 3.4 kilobases (kb), was identified and subjected to further analysis. On mapping by Southern hybridization[9], the insert of this clone was found to contain two different segments hybridizing to the *Alu* probe. I sequenced one of these segments and 500 bp of flanking DNA (Fig. 2). The *Alu* repeat displays 77% homology to a human *Alu* consensus sequence[8] and is flanked by 9-bp-long direct repeats. On its 3′ side it is followed immediately by a dAMP-rich region of almost 100 nucleotides. Of the point mutations present in the sequence, only 30% represent transversions, in agreement with the types of divergence found among *Alu* repeats[10]. Therefore, no significant postmortem modifications seem to have affected the nucleotide sequences analysed, even if chemical sequence alterations affecting a very small proportion of the nucleotides cannot be excluded. The DNA sequences flanking the *Alu* repeat show no statistically significant homology to any known DNA sequences contained in a DNA sequence bank[11].

These results establish the feasibility of faithfully cloning substantial pieces of genomic DNA from biological remains of great antiquity. The yield of DNA from this unusually well-preserved mummy was ~20 μg per g dried tissue, which approaches 5% of the amount expected from fresh tissue. Note, however, that most of the mummy samples investigated seem to be devoid of nucleic acids. Interestingly, the general histological preservation of the various mummy tissues was much better in superficial tissues and peripheral parts of the bodies than in the more deeply situated tissues, an observation made also by others[12,13]. This probably results from the fact that the mummification process in Ancient Egypt consisted of dehydration of the eviscerated body by embedding it in crystalline salts (natron)[14]. Thus, the parts of the body in direct contact with the dehydrating agent may have dried out first, thus shortening the time that hydrolytic processes acted upon macromolecules in these tissues. Future attempts to clone genes from Ancient Egyptian human remains should therefore be directed towards superficial tissues.

The present report, as well as the recent cloning of mitochondrial DNA sequences from the dried skin of a quagga, extinct for ~100 years[15], raise the hope that recombinant DNA techniques may be applied systematically to archaeological samples. Thus, Ancient Egyptian mummies represent a unique material that could allow diachronic studies of the frequencies of polymorphic genes in the Egyptian population since neolithic times, as well as study of the evolution of DNA-containing viruses over the same time period. Finally, a number of Egyptological problems can now be approached, such as the descent of the ancient population in the Nile valley (see ref. 16 for review) and relationships between Pharaonic dynasties as well as individual relationships between members of the Pharaonic families[17–19].

I thank many people for help in this study, including Drs Kenth Gustafsson, Ann-Charlotte Runn and Göran Possnert for help with DNA sequencing, preparation of histological sections and accelerator mass spectroscopy, respectively. Drs R. Holthoer, W. Müller, F. Parsche and F. W. Rösing have generously provided mummy samples. I also thank Professors P. A. Peterson, W. Schaffner and R. Holthoer for encouragement and support. Financial support was provided by a Lennander grant from the Medical Faculty of the University of Uppsala.

COMPUTED TOMOGRAPHY OF THE BODY

NOW IN PAPERBACK

A Radiological and Clinical Approach

Janet E. Husband MRCP, FRCR Ian Kelsey Fry DM, FRCP, FRCR

'As a general text on computed tomography this book may be thoroughly recommended.' British Medical Journal

'... A much needed book that will be of use to all those involved in CT scanning and should be read by all radiologists in training – their examiners will certainly have read it.'
British Journal of Radiology

'I would highly recommend this book to anyone interested in learning about computed body tomography.'
American Journal of Roentgenology

Contents
The Contributors; Preface; Basic Principles with R. Parker; General Considerations – Technical; General Considerations–Clinical; The Thorax – Mediastinum; The Thorax – Lungs, Pleura and Chest Wall; The Abdomen – Kidney; The Abdomen – Adrenals; The Abdomen – Liver and Biliary Tract; The Abdomen – Pancreas; The Abdomen – Miscellaneous Topics; Lymph Node Disease of the Abdomen and Pelvis; The Pelvis; The Musculo-Skeletal System; The Spinal Cord by P. Pullicino; The Head and Neck with C.A. Parsons; The Orbits by G.A.S. Lloyd; Computed Tomography in Oncology; Index.

SAFETY TESTING OF NEW DRUGS

Edited by D. R. Laurence, A. E. M. McLean and M. Weatherall

1984, 184pp., $28 00/£19 00 (UK only), ISBN: 0.12.438350.5

For the last twenty years, license to market new medicine in most Western countries has depended on the approval by regulatory bodies of data on laboratory experiments and clinical trials. The data are submitted in confidence and mostly remain unpublished The aim of regulatory bodies is to protect the public from unsafe drugs, but their procedures are not alway effective, and occasionally medicines have been approved and subsequently discredited. It is therefore desirable that the kind of data on which decisions are made should be open to public inspection. By the generous cooperation of several pharmaceutical companies, hitherto unpublished data are now made available, and are evaluated in the light of subsequent clinical experience.

GENETICS OF BACTERIA

Edited by J. G. Scaife, D. Leach and A. Galizzi

1985, 272pp, $59.00/£45.00 (UK only), ISBN 0.12 621180.9

The book covers all the major genetic aspects of bacteria, their plasmids, and phages mutation· gene transfer and recombination, the transposition of genetic elements, and the mechanism and control of gene expression. Special emphasis is placed on *Escherichia coli*. In addition, *Bacillus subtilis*, a Gram-positive organism which has unique features as a genetic system, is introduced. For those wishing to study other bacteria a list of helpful references is provided at the end of Chapter One

ECOTOXICOLOGY

The Study of Pollutants in Ecosystems

F. Moriarty

1983, 240pp., $35 00/£22 00 (UK only), ISBN. 0.12.504760.7

The effects of pollutants on both ecosystems and individuals depend on the exposure to, and dose of, the pollutant, but in ecotoxicology, and distinct from toxicology, the significant effect is measured on species populations, not on individual organisms Failure to grasp this distinction has led to false conclusions, and the significance of much relevant ecological knowledge has been missed. This book has been written to remedy this shortcoming.

COMPARATIVE BIOCHEMISTRY AND PHYSIOLOGY OF ENZYMATIC DIGESTION

H. J. Vonk and J. R. H. Western

1984, 512pp, $80.00/£55 00 (UK only), ISBN· 0,12 727850.8

The ability of animals to consume and digest a wide range of organisms and organic materials is well established and a considerable literature has accumulated. Whereas most accounts concentrate on one animal or group of animals only, this book sets out to collate details of the digestive enzymes from the spectrum of metazoan animals and to facilitate comparison of the enzymes and digestive mechanisms in the different groups. Conclusions are given at the end of each chapter

ENZYME NOMENCLATURE

1984, 672pp., $45.00/£36 00 (UK only), ISBN· 0 12 227162 9 (Cloth)
1984, 672pp., $19 50/£16 00 (UK only), ISBN 0.12.227163 7 (Paper)

Recommendations of the Nomenclature Committee of the International Union of Biochemistry on the Nomenclature and Classification of Enzyme-Catalysed Reactions. This edition is a revision of the Recommendations (1978) of the Nomenclature Committee of IUB, and has been approved for publication by the Executive Committee of the International Union of Biochemistry.

FORTHCOMING VOLUMES IN OUTSTANDING SERIES...

INTERFERON

Volume 6

Edited by Ion Gresser

1985, In Preparation, ISBN. 0.12.302255.X

Each year Ion Gresser and the Editorial Board of the *Interferon* series highlight the areas of current interest in interferon research and so provide a forum of the diverse aspects of this research. Now in its fifth year, this volume follows the established format that with rapid publication allows research workers to keep apace with current developments in this exciting and fast-moving field.

Contents: *Evolution of Interferon Genes,* **T. Miyata, H. Hayashida, R. Kikuno, H. Toh, and Y. Kawade.** *Interferons and Cell Differentiation,* **G. B. Rossi.** *Immunomodulation by Interferons: Recent Developments,* **J. De Maeyer-Guigard and E. De Maeyer.** *How Does Interferon Inhibit Tumor Growth?,* **I. Gresser.** *Interferon· A Model for Future Biologicals,* **R. K. Oldham.**

TECHNIQUES IN IMMUNOCYTOCHEMISTRY

Volume 3

Edited by G. R. Bullock and P. Petrusz

1985, In Preparation, ISBN· 0.12 140403.X

Contents: *Fixation parameters for immunocytochemistry. The effect of glutaraldehyde or (para) formaldehyde fixation on the preservation of mononuclear pagocyte differentiation antigens.* **Pieter J. M. Leenen, Anita M. A. C. Jansen and Willem Van Ewijk.** *Immunocytochemical labelling of monoclonal antibodies by the APAAP immuno-alkaline phosphatase technique* **David Y. Mason.** *Application of avidin-biotin complex technique for the localisation of estradiol receptor in target tissues using monoclonal antibodies.* **Madhabananda Sar.** *The immunoblotting technique for the characterisation of antibodies used in central nervous system immunocytochemistry.* **Richard Cumming and Robert D. Burgoyne.** *Microinjection and immunofluorescence microscopy as tools to study cytoskeletal organisation in tissue culture cells* **Paul M. Mangeat and Keith Burridge.** *Quantitation of monoclonal antibody binding to individual cells by cytophotometry.* **P. H. Nibbering, P. C. J. Leijh and R. van Furth.** *Immunocytochemistry of regulatory peptides.* **Susan Van Noorden and Julia M. Polak.** *The gold method as applied to lectin cytochemistry in transmission and scanning electron microscopy.* **Marc Horisberger.** *The enzyme-gold technique: a new cytochemical approach for the ultrastructural localisation of macromolecules.* **Moise Bendayan.** *Colloidal gold and colloidal silver – metallic markers for light microscopial histochemistry.* **John M. Lucocq and Jurgen Roth.**

ESSENTIAL FOR THE EXPERIMENTAL BIOLOGIST...

THE **BIOLOGICAL TECHNIQUES SERIES**

Series Editors J. E. Treherne and P. H. Rubery

TECHNIQUES IN PHOTOMORPHOGENESIS

Edited by H. Smith and M. G. Holmes

1984, 336pp., $65.00/£45.00 (UK only), ISBN: 0.12.652990.6

This volume has been written as a coherent and authoritative guide for all those experimenting on the control of plant growth and development by light. It is intended to be used as a laboratory manual, with practical advice taking precedence over theory, although exposition of theory underlying the techniques has been included where essential

INTRACELLULAR STAINING OF MAMMALIAN NEURONES

A. G. Brown and R. E. W. Fyffe

1984, 128pp., $23.00/£14.00 (UK only), ISBN: 0.12.137220 0

The use of intracellular injections of horseradish peroxidase in combined electrophysical/anatomical studies of mammalian neurones has been a key factor in the advancement of neuroscience research. In this volume, two of the leading figures in the development and refinement of the techniques involved, provide for the first time a comprehensive set of instructions for their use.

This book will be welcomed by neuroscientists in all fields, looking for a detailed and authoritative introduction to these important techniques.

OTHER VOLUMES IN THE BIOLOGICAL TECHNIQUES SERIES

ADVANCE ANNOUNCEMENT...

SPECTROSCOPY AND THE DYNAMICS OF MOLECULAR BIOLOGICAL SYSTEMS

Edited by P. M. Bayley and R. E. Dale

1985, In Preparation, ISBN: 0.12.083240.2

This volume reviews a range of modern methods for the study of the dynamic processes of individual biological molecules and of molecules in integrated macromolecular and membrane systems. State of the art studies of recently developed time resolved techniques, notably using lasers and synchrotron radiation, optical techniques such as fluorescence anisotropy and photobleaching, triplet spectroscopy and correlation methods and ESR techniques are presented as reviews by expert practitioners.

INTRODUCTION TO GENETIC TOXICOLOGY

Written and Translated by **J. Moutschen,** *University de Liege, Belgium*
With a Preface by **L. Ehrenberg,** *University of Stockholm*

Genetic Toxicology as a discipline examines the short and long-term effects of all physical and chemical agents in the environment on the human genetic system. It is a relatively new, but now fast-growing field of research as more and more substances are found to have unexpected long-term genetic side-effects. This short introduction includes in one volume various methodologies for assessing toxicity; a classification of potential mutagenic pollutants according to their danger to man; and finally some possible solutions to genetic toxicology problems. This material has been amended and substantially updated for the English edition.
The ideas discussed in this book are of vital importance to a wide range of researchers, and for this reason, the aim throughout has been to keep the whole text accessible to the non-specialist, with more detailed information available via the comprehensive references and lists of further reading.

0471 90143 1 200pp April'85 £18.50

MAMMALIAN CELL GENETICS

by **M.L. Hooper,** *University Medical School, Edinburgh, Scotland*

Presents a comprehensive treatment of the genetic analysis of mammalian cells cultured as independent microorganisms. It bridges the gap between introductory texts and advanced works which describe selected aspects of the subject.

Contents: The Cultured Mammalian Cell; Selective Techniques; Cell Variants; Cell Heterokaryons and Hybrids; Molecular Somatic Cell Genetics; Cell Genetics and the Germ Line; Index.

0471 89201 7 192pp March'85 £63.25

MEMBRANES: ENDO- AND PLASMA MEMBRANES OF PLANT CELLS

by **D.G. Robinson,** *University of Gottingen, Germany*

This monograph treats the isolation, structure, function, biogenesis and turnover of plant cell membranes, stressing the correlation of structure with function, with particular emphasis on biochemical investigation. It includes numerous electron micrographs.

Series: Cell Biology: A Series of Monographs, Volume 3

Contents: THE STRUCTURE AND ISOLATION OF PLANT CELL MEMBRANES: Endoplasmic Reticulum; Nuclear Envelope; Microbodies; The Golgi Apparatus; Tonoplast and Vacuoles; Plasma Membrane; Coated Vesicles; MEMBRANE AND PARTICULAR FUNCTIONS OF PLANT CELLS: Microfibril Synthesis and Orientation; Synthesis and Secretion of Extracellular Macromolecules; Synthesis, Accumulation, and Breakdown of Storage Products; The Vacuole and Compartmentation; Recognition Phenomena; Membranes and Cell Division; BIOGENESIS AND TURNOVER OF PLANT CELL MEMBRANES: General Principles; For Comparison; The Case in Animal Cells; The Case in Plant Cells; A Special Case: Wounded Tissues; Index.

0471 86210 X 352pp Jan'85 £80.40

PRINCIPLES OF GENETICS, 7th Edition

by **E.J. Gardner,** *Utah State University,* and **D.P. Snustad,** *University of Minnesota*

An up-to-date, well balanced text covering the basic principles of genetics. It includes a thorough updating in the rapidly changing area of molecular genetics, and presents new material on restriction enzyme mapping, DNA sequencing, the genetic control of antibody structure, oncogenes and proto-oncogenes, and much more. New problems, high quality illustrations, and end-of-chapter summaries are also included.

0471 87610 0 662pp April'84 (cl) £40.50
0471 89203 3 662pp April'84 (WIE) £16.95

THE ADAPTIVE ROLE OF LIPIDS IN BIOLOGICAL SYSTEMS

by **N.F. Hadley,** *Arizona State University*

A unique compilation of diverse data on the lipid, treating the role of this group of organic compounds in the adaptions of plants, animals and microorganisms. It presents a blend of lipid biochemistry, physiological function, adaptation and evolutionary biology. After initial chapters introducing background material, each subsequent chapter deals with the role of the lipid in a specific biological or physiological function.

0471 09049 2 332pp March'85 £50.60

METHODS OF BIOCHEMICAL ANALYSIS Volume 30

edited by **D. Glick,** *Cancer Biology Research Laboratory, Stanford University, Medical Center, Stanford, California*

Annual Review volumes dealing with many different fields of science have proved their value repeatedly and are now widely used and well established. These reviews have been concerned, not only with the results in the developing fields, but also with the techniques and methods employed and they have served to keep the ever-expanding scene within the view of the investigator, applier, the teacher, and the student. The volumes in this series are designed to try to meet the need in the field of biochemical analysis. The topics to be included are chemical, physical, microbiological, and if necessary, animal assays, as well as basic techniques and instrumentation for the determination of enzymes, proteins and their products, minerals antimetabolites, etc.

0471 80276 X 388pp June'84 £62.70

MARINE BIOLOGY OF THE POLAR REGIONS AND EFFECTS OF STRESS ON MARINE ORGANISMS

edited by **J.S. Gray,** *Institute of Marine Biology and Limnology, University of Oslo* and **M.E. Christianson,** *Zoological Museum, University of Oslo*

The 18th meeting in this annual symposium series, organised by the University of Oslo, reflected the two key features of northern and polar waters: their naturally rich marine life and the heavy use made of them by man.
Important review papers highlight how both higher and lower marine organisms are adapted to this environment, and in particular how changes in these conditions affect an organism's life-cycle, with perhaps far-reaching consequences in the vast marine food chain.
This book presents a number of useful studies examining actual effects of specified contaminants on various organisms.

Research in the market-place

Dorothy Nelkin

The Interferon Crusade: Public Policy and Biomedical Dreams.
By Sandra Panem.
The Brookings Institution, 1775 Massachusetts Avenue NW, Washington DC/ Costello, 43 The High Street, Tunbridge Wells, Kent: 1984. Pp. 109. Hbk $22.95, £31; pbk $8.95, £12.10.

"A MAGIC bullet", "a priceless miracle drug", "a cure for cancer", "a wonder therapy" — it was in these terms that the public was exposed to research on interferon. Interferon has been the most visible and dramatic product of the rapidly expanding biotechnology industry. The story of its development and the hyperbole that surrounded it reflect the mix of scientific, political and economic events that has generally shaped the biotechnology revolution. It is a story of promises and problems, of complex arrangements between government, industry and academia, and of the policy dilemmas of a fast-moving and potentially profitable field of research.

Sandra Panem's book, *The Interferon Crusade*, begins with the discovery in the 1950s that the body produces a natural therapeutic agent, "an interfering proton" to inhibit infections. Panem traces the development of interferon, documenting the discovery of its anti-tumour activity in 1967, the publicity about its potential as a cancer cure in the mid-1970s, and finally the successful cloning of a human interferon gene in late 1979. She writes also about the role of advocacy scientists, those key individuals who publicize research, capitalizing on the public fear of cancer in order to raise funds.

As Panem observes, the explosion of interest in interferon resulted mainly from its promise as a cure for cancer. The ability to synthesize the drug through genetic engineering techniques, and therefore to produce it inexpensively, aroused commercial attention so that interferon became the primary lure for trapping venture capital for biotechnology firms. The case of interferon reveals the complex institutional relationships involved in new technologies. It engaged scientists and politicians in marshalling resources to develop the technology; it attracted the interest of the press; and eventually it succeeded in mobilizing public curiosity and venture capital. The academic community, the government and the private sector developed close relationships.

The book points to the controversial policy issues raised by these relationships — the effect of extra-scientific factors such as media attention in setting research priorities, for example, and the influence of commercial interests on academic research and on the behaviour of the scientific community. It also deals with the conflicts over open disclosure of research findings, the manpower problems of a rapidly expanding scientific and technical field, the ethical and legal consequences of the changing relationship between science and industry, and the complexity of funding patterns that arise from the involvement of both the public and the private sectors.

"Forget the heroin business, Bugsy! I've something more profitable lined up!"

ACCORDING to a report prepared by the US brokerage and investment firm Bache Halsey Stuart Shields, interferon sales could have a world wide market of $2 billion a year within three to five years. The report, summarised in *European Chemical*

Interferon fever — cartoon and news report from *Nature* May 1980.

Panem is at her best when she discusses the history of the development of interferon, and its scientific importance in molecular biology and immunology despite its failure in the short term as a therapeutic agent. She writes skilfully of the dynamics of the biotechnology industry and the role of media, both in shaping research priorities and attracting industrial interest. The people, the firms, are real, and their activities are richly portrayed. However, she presents the key policy issues as little more than a list. There is much more to be explored in the problems of secrecy so often observed as a consequence of the new associations between science and industry engendered by the growth of biotechnology. How great a problem is secrecy in science? What kind of contracts are being developed, and what is their effect? What is the actual influence of non-disclosure on scientific productivity?

One suspects the changing relationship between science and scientists and their sponsors is also changing the prestige system in science. Rewards are increasingly coming from consulting contracts, from participation on corporate boards. What does all this mean? At some universities entire biology departments have been redirected to research in genetic engineering and biotechnology-related research. What does this imply for the training of students, and more generally, for the wider range of biological research? There are also many questions to be asked about the selling — the overselling — of science, and Panem makes a fascinating observation about the role of "hype" on funding patterns. Between 1978 and 1981 the increase in government spending on interferon research greatly outpaced the overall rate of growth in biomedical research in general. Yet the peer review ratings were much lower, suggesting how politicians more than peers can shape scientific priorities. What are the implications of this pattern of funding "hot" research subjects before good proposals are developed? When commercial interests influence research funding, what does this do to the ideal of science as an autonomous, neutral activity? While the focus on fashionable areas of research has implications for science itself, there are perhaps more serious implications for the rest of us.

The overselling of interferon also bears on the credibility of science as a whole. In many cases, scientists contributed to media publicity, believing that it was an effective way to attract support. But this also created inflated public expectation and then disillusion as delivery of therapeutic benefits was delayed. As one journalist cynically observed about interferon, "At only a hundred trillion dollars a gram, this miracle drug has a future".

Panem competently outlines the policy dilemmas intrinsic to this revolutionary area of research, but she offers no point of view. Her descriptions of the "interferon crusade" are balanced, but bland: she takes no position on the many controversial issues that she lists. Her view, as stated in the introduction, is that "understanding the interferon experience may prove useful in predicting future problems of biomedical research [and] other scientific areas as they experience technical revolutions". She has laid the groundwork for such an understanding, but it remains for others to examine with a more critical and analytical eye the dilemmas that are outlined in her book. □

Renewed interaction

Peter D. Moore

Allelopathy, 2nd Edn.
By Elroy L. Rice.
Academic: 1984. Pp.422. $55, £42.50.

PERHAPS the best possible excuse for writing a second edition of a book is when the author changes his mind about the definition of the title; this becomes even more imperative when the title is a single word, such as allelopathy. When Rice wrote the first edition of this book in 1974, he adopted a conservative definition and confined his attentions to those chemical interactions between plants (including microbes) which result from the release of compounds into the environment and which cause harm to the recipient. He now feels that the definition was too narrow and that the term should include stimulatory interactions, and in this respect he comes into line not only with the coiner of the word (Molisch) but also with many others who use it.

Predictably, wider use of the term has resulted in the second edition including information which was excluded from the first. Hence it is a fatter book. But there is also a marked change in emphasis, for almost a third of this edition is devoted to what may be regarded as applied aspects of the subject, such as the importance of allelopathic studies in agriculture, horticulture and forestry. Further semantic problems occur even in these fields, as in the case of such well-known weeds as *Camelina sativa* in flax fields. It has long been known that flax plants in the immediate vicinity of the weed suffer reduction in growth rate, but is this due to allelopathy or to "competition" for some environmental resource such as nutrient ions? Both views have been held by various workers and chemical tests on plant exudates have not clarified matters, for leaf washings of *Camelina* have often been found to stimulate the growth of young flax plants. The latest work quoted by Rice suggests that benzylamine, secreted by *Camelina*, stimulates flax at concentrations below 100 ppm, while above 200 ppm it serves to inhibit it. So here we encounter problems both in the definition of allelopathy and of competition which are currently dogging the study of this subject.

In the analysis of allelopathic interactions in natural vegetation, emphasis has often been placed upon the occurrence of bare patches around plants or of patterns exhibited by plant populations. This work is thoroughly reviewed here, both for herbaceous and for woody species. The involvement of microbial elements in the plant interactions also receives due attention, as for example in the discussion of nitrification and the extent to which late successional species produce chemicals which inhibit the process and thereby gain advantage over those species with the potential to replace them. This is a subject which generates strong feelings among ecologists and it is well reviewed by Rice, who, predictably, comes down in favour of the idea of succession suppression by dominant plants.

From the ecological, we are taken into the realms of physiological and biochemical studies of allelopathy, including the chemical nature and the mode of transfer and action of the active agents.

The subject of allelopathy is one which transgresses a number of disciplinary boundaries and which can be expected to interest a wide readership. The first edition of this book certainly spent more time off my shelves than on them and is now very well worn. Such intensity of use, which I am sure is widespread, coupled with the amount of research into allelopathy over the past ten years, amply justifies the publication of a second edition even if the author had not revised his opinion on the definition of the term. □

Peter D. Moore is Reader in Ecology in the Department of Plant Sciences, King's College, University of London.

Ice age development

G. de Q. Robin

Ice Sheets and Climate.
By J. Oerlemans and C.J. van der Veen.
Reidel: 1984. Pp.217. Dfl.90, $34.50.

Ice Sheet and Climate Modelling would have been a better title for this work, which aims to help graduate students bridge a gap between glaciology and climatology. The authors' views and research contributions are presented concisely in relation to brief outlines of our knowledge of the climate system and of the work of other modellers.

In 12 short chapters descriptions and relevant equations are presented, starting with the global climate system. Here the energy balance, transport by atmosphere and oceans, and related effects of albedo feedback on these systems are covered. A largely mathematical outline is given of ice dynamics, including flow of ice shelves and grounding lines problems. Economical methods of numerical modelling are then introduced, and are later applied to problems of growth, decay and stability of ice sheets in the Northern Hemisphere and the climatic stability of ice sheets of Greenland and Antarctica.

Adequate modelling of vast ice sheets must involve their heat budget and bedrock adjustment to ice loading. Oerlemans and van der Veen avoid lengthy analysis of frictional heat production from stress–strain rate distribution by equating the loss of potential energy to total frictional heat production in steady-state ice sheets. Their analysis of bedrock adjustment is similar to that found earlier works, but leads to more sweeping conclusions.

In the book, the approximate 100,000-year cycle of growth and decay of Pleistocene ice sheets is attributed to flow dynamics of the asthenosphere and ice sheet once growth is initiated. The authors place less emphasis than others on latitudinal variations of radiation with time as a controlling factor. Even so they consider such variations are one likely cause of initiation of ice ages, with the next suitable minimum at 65°N at 50,000 years being much more likely to start an ice age than the earlier but less severe minimum around 20,000 years. In the near future, they calculate, warming of the atmosphere by doubling of the carbon dioxide content will deposit more ice on Antarctica (where melting is negligible) while on Greenland total melting would increase more than accumulation. The assumption that ice flow changes are negligible over a short period leads to estimated mass changes of the two ice sheets that together would lower sea level by 0.1m in 250 years.

When linking heat flow to large-scale ice dynamics, Oerlemans and van der Veen reach similar conclusions to other studies but with two exceptions. They reject internal strain heating of cold ice and frictional enhancement of sliding by ice melting as likely causes of major ice surges, pointing out that some conditions that lead to surging of valley glaciers do not apply to ice sheets. They do however conclude that basal trapping of water beneath ice sheets could result in large-scale cyclic surging. At this point, in moving on to develop models that could work rather than first discussing if these are plausible, it seems that the cart is put before the horse. Surely beneath fast-moving ice streams, sometimes termed "continuously surging glaciers", water trapping must be stable and continuous rather than intermittent. Since such ice streams discharge a large fraction of Antarctic ice, the authors could query whether really large-scale surges are possible. Neither modelling studies nor field data seem to provide strong evidence in their favour.

Although it is apparent that English is not the authors' mother tongue, the book is clearly written and presented. Its broad conclusion is that ice-asthenosphere dynamics drive an ice age — once it is triggered off — rather than climatic factors driving ice sheet dynamics. Oerlemans and van der Veen do not claim to provide final answers, but they have produced a stimulating book that should, as they intend, result in further and more detailed research in this field. □

G. de Q. Robin is at the Scott Polar Research Institute, University of Cambridge.

● Cambridge University Press has issued paperback editions of *Theory and Experiment in Gravitational Physics* (by Clifford M Will) and *The Very Early Universe* (edited by G.W Gibbons, S.W Hawking and S.T.C. Siklos). Price of each book is £15, $24.95. For reviews see *Nature* **299**, 284 (1982) and **309**, 473 (1984).

Remains of humanity

Yoel Rak

The Origins of Modern Humans: A World Survey of the Fossil Evidence. Edited by Fred H. Smith and Frank Spencer.
Alan R. Liss: 1984. Pp.590. $70, £53.

IN THE late 1930s only the fact that a group of human fossil remains was discovered at the same site on Mount Carmel spared each specimen from being assigned to a different taxon — a "separate form of humanity". There can be no better manifestation of the changes in approach and thought regarding the appearance of anatomically modern *Homo sapiens* than the articles offered in *The Origins of Modern Humans*. There has long been a need for such a volume, to bring together data on the enlarged fossil record and demonstrate the innovations in our methods of assessment of that record. One is reminded that almost 30 years have passed since the appearance of the last attempt to summarize the state of the art in this area, *Hundert Jahre Neanderthaler 1856-1956*, published in commemoration of the hundredth anniversary of the first Neanderthal discovery.

Of the 11 contributions in the book, the first two are of a general nature. F. Clark Howell introduces matters with a comprehensive survey that in essence summarizes the contents of the whole volume. And as historical background and past ideologies must be considered in any attempt to assess theories of the appearance of modern humans, the second chapter, written by F. Spencer, concentrates on the history of the fossil discoveries and their interpretations. It is unfortunate, however, that the three main evolutionary models of early *H. sapiens* so clearly depicted by Spencer are again independently described several times in following chapters, creating a rather tedious redundancy.

The heart of the book consists of the nine remaining contributions, which are devoted to the skeletal remains found in various regions of the Old World and the New: Europe (covered by C.B. Stringer, J.J. Hublin, B. Vandermeersch; F. Smith; and D. Frayer); western Asia (E. Trinkaus); Africa (P. Rightmire, G. Brauer); east Asia and Australasia (M.H. Wolpoff, Wu X.Z. and A.G. Thorne); China (C.L. Brace, Shao X-q. and Zhang Z-b); and the Americas (R.C. Owen). The articles are to a large extent organized according to a similar pattern. Initially there is an up-to-date account of the fossil record and its chronology, thus allowing the reader to become acquainted with a number of little-known specimens, that being followed by interpretation of the fossils, primarily phylogenetic. The geographical scope of the book as a whole is both broad and well-balanced; as such it is refreshingly free of the Eurocentric bias that, as the editors remind us, formerly plagued anthropological thought. Similarly, the range of approaches and opinions of the various authors reflects most of the current thinking on the topic. Only by close attention to the differences in approach to morphology and to the differing biological models of each author will the reader comprehend how the same group of specimens is considered "archaic", "primitive" and "generalized" by some, and "advanced", "specialized", "derived" and "modern" by others.

The views of most of the contributors are already well known, but publication of their current research in one volume provides for the first time an overall perspective on the appearance of anatomically modern *H. sapiens*. Because of the range and diversity of the contributions, the references accumulated here by themselves constitute a veritable treasure trove.

Still, there are some criticisms. Detection of the polarity of a morphocline in the period under discussion is admittedly difficult because of the relatively short time span involved, the polymorphic nature of the species, and, lastly, the fully modern volume of the brain in the hominids considered (a criterion which had dictated polarity in earlier stages of human evolution). Nevertheless, more of the contributors could have attempted to deal with the question of evolutionary trends through a more rigorous functional interpretation of particular morphologies. Culture with its effects on morphology is the primary topic of those who do offer an adaptive interpretation. Such an approach, along with precise dating, might ensure that a greater degree of certainty could have been accorded the somewhat speculative statements on migration, local development and replacement.

The importance and overall quality of the book are not seriously marred by several other deficiencies. A world map showing all the sites mentioned would have been most useful (the two maps which do indicate sites unfortunately portray the same region and most of the same fossil locations), while the quality of some of the photographs and drawings leaves much to be desired. A greater effort could have been made to standardize the names of fossils and sites; the skull from Saldanha, for example, appears under three different names. Finally, although the book deals with the fossil evidence, some reference to genetic studies would have been in order.

The editors and contributors to this book have provided us with an enlightening review of the problems surrounding the origins of anatomically modern *H. sapiens*. Readers will need some prior familiarity with the fossil record, and with anatomy and population genetics. For such people this will be an invaluable source of reference. □

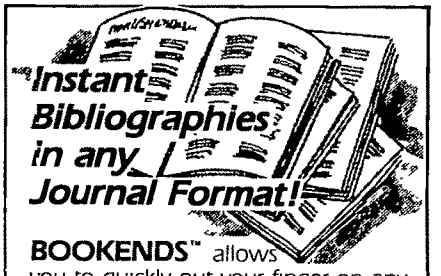
NUCLEAR POWER AND ITS ENVIRONMENTAL EFFECTS

For the Layman, Nuclear Technician, Manager

Places the effects of possible nuclear radiation in perspective. Meets the need for a better understanding of radiation and its consequences especially after the TMI accident.



All vital aspects of nuclear power generation are considered, from fundamental principles to plant licensing, from uranium mining to disposal of waste. The safe operation of nuclear power plants, to prevent the escape of dangerous amounts of materials in case of an accident, is fully covered.

Ultrastructuralism

Michael Ashburner

Insect Ultrastructure. Vol.1 The Ultrastructure of Gametes. Vol. 2 The Ultrastructure of Developing Cells.
Edited by Robert C. King and Hiromu Akai.
Plenum: 1982/1984. Vol. 1 pp.624, $55, £52.25. Vol. 2 pp.650, $85, £80.75. Two-volume set $127.50, £121.13.

IN September 1969 the Royal Entomological Society of London held a symposium called "Insect Ultrastructure". Of the eleven people who contributed to it five were, or had been, members of the Department of Zoology in Cambridge. Surprising, considering that the meeting was organized by an Oxford man. The present two volumes have 49 contributors, only one of them from Cambridge Zoology. But then only one, David Spencer Smith (to distinguish him from all the other eminent biologists, let alone Oxford professors, called David Smith), has contributed to both of these volumes and to the 1969 symposium. David Spencer Smith is, now, in Oxford.

Who will read such volumes as these, 31 chapters on the ultrastructure of insects? I suppose there are those who will read anything on structure if it is ultra, whether from bees or bats. There are, I know, those who will read (almost) anything on insects, from ultrastructure to sociobiology. For these readers the two books suffer from a serious lack of balance. Some of the chapters are very narrow, others paint on a broader canvas. For example at one extreme we have Sorsa's review of the ultrastructure of the polytene chromosomes of *Drosophila melanogaster*. I have no quarrel with Sorsa's chapter as a contribution to science (at least no quarrel worth airing in these pages) but the ultrastructuralist or entomologist reading these volumes should be warned that it is very much a review of Sorsa's own work and makes no attempt to review the field comprehensively. Moreover there can be few who require 10 pages of a detailed map of the banding pattern of chromosome arm 2L. An $85 book is not a suitable medium for its publication.

Another example of a review whose field is narrow is that by Rasmussen and Holm on the ultrastructure of meiotic prophase in the silkmoth, *Bombyx mori*. I am sure that this is a subject worthy of review. That is not my complaint. My complaint is that in a large and expensive work called *Insect Ultrastructure* the purchaser might expect a more comprehensive review of, for example, meiotic prophase in insects or, perhaps, of meiosis in *B. mori*. I must not give the impression that all of the chapters are as narrow in their compass as these. Many, indeed, will be of interest to biologists with a wide range of interests, David Spencer Smith's review of the ultrastructure of insect muscle being one such.

In addition to the two classes of omnivorous reader there are those (and here I include myself) who approach volumes like these with the attitude of a selective browser. We will read chapters in this book for one (or more) of four reasons: (i) because we need to know what is going on in a particular field of research (which may be our own); (ii) because we always wanted to know about, for example, neuromuscular junctions in the Orthoptera but never, before, knew who to ask; (iii) because we are intrigued by the title of a particular chapter; or (iv) because we once met Professor Kafatos at a conference banquet in East Idaho and always wondered what he did for a living. For the selective browser balance is irrelevant; these volumes are a lucky dip to which he can return over and over again.

It is interesting, for an outsider whose practical experience of insect ultrastructure is limited to peering over Nancy Lane's shoulder at a glowing screen, to compare Neville's 1969 volume and David (Spencer) Smith's 1968 book *Insect Cells: Their Structure and Function* with these volumes. Two overall impressions. The first is the importance of technical advances: not only that the slow but steady improvement in preparative techniques has led to far better electron micrographs, but of methods such as scanning electron microscopy (in its infancy in 1968), freeze fracture, chromosome spreading and reconstruction from serial electron micrographs that are now routine tools. The greatest contrast, though, is that the two earlier books, Smith's especially, left one with a very static view of structure, making the necessary relationship between structure and function difficult to draw. Now, however, I get a real feeling for dynamic processes, of the importance of the change in structure, and hence function, with time. It is impressive to see how much the study of insect ultrastructure is now the adjunct of the experimental biologist, rather than the preserve of the morphologist. □

Michael Ashburner is Reader in the Department of Genetics, University of Cambridge.

• Next week's issue of *Nature* includes the Spring Books Supplement, 25 pages of reviews from, among others, W.F. Bynum, Richard C. Lewontin, Nevill Mott, David Park, Owen Gingerich, David Bohm and Anthony Clare.

Sea slugs: beauty in biology

Elizabeth B. Andrews

Biology of Opisthobranch Molluscs, Vol. II.
By T.E. Thompson and G.H. Brown.
The Ray Society, British Museum (Natural History), London: 1984. Pp.229. £39.

THE delicacy of shape and the beauty of colouring of sea slugs, the animals with which this volume deals, have captured the attention and admiration of many zoologists, amateur and professional. Their agility and grace of movement contrast markedly with the drabness and ponderous crawling of their terrestrial relatives and with their own dreadful deadness when pickled. They have remained a rather neglected group by comparison with both prosobranch and pulmonate gastropods, however, due partly to their unreliable occurrence and partly to the fact that many species are particularly abundant in those marine habitats that are most difficult to explore — too low for shore collecting, too shallow for adequate boat-work. The first difficulty still remains, and some species are genuinely rare. Scuba diving has largely abolished the second, however, and one reason for the success of this book is that both authors are accomplished divers and have thus found not only more specimens for study but also more species new to the area covered by their work.

The authors offer a taxonomic survey of the nudibranch gastropods found in British waters, with keys and illustrations to help identification. They give brief definitions of subordinal and familial characters, and for each species provide details of appearance, anatomy, feeding, breeding and a brief synonymy. Local distribution is recorded in a series of maps, and foreign distribution is mentioned, and there are short discussions of taxonomic problems, a very complete list of references and a helpful index. The book also benefits from the provision of an "Epilogue": a summary of ideas and information relating to opisthobranchs published since 1976 when Vol. 1 appeared.

Illustrations are important in any book dealing with such photogenic subjects as nudibranchs, and comparison with The Ray Society's previous publication on the group, Alder and Hancock's *A Monograph of the British Nudibranchiate Mollusca* (1845–1855), with its beautiful figures, is inevitable. Thompson and Brown's work stands up to the comparison with distinction: all but two species are illustrated in a series of plates on which paintings of the animals stand against a black background, lifelike and attractive. In addition, each species is shown in black and white, a helpful guide for the student.

For all interested in this group of animals the book will be an essential acquisition. It is an excellent addition to the series which The Ray Society has produced for so long, and a worthy successor to Alder and Hancock's *Monograph*. □

Elizabeth B. Andrews is Senior Lecturer in Zoology at Bedford College, University of London.

Biodata Handling with Microcomputers

by R B Barlow

Student's 't' test, Mann Whitney 'U' test, Wilcoxon signed rank test, 4-point assay with confidence limits, Spearman rank correlation coefficient, linear regression, Hansch analysis, enzyme kinetics by direct fit, radioimmunoassay, radioligand binding assay and much, much more

A manual giving the mathematical background to dozens of analytical methods in the biosciences, showing how they are transformed into (fully listed) BASIC programs, illustrated by worked examples

Chapters include Operating a computer; Some statistical programs, Line-fitting by least squares, Some applications to chemical ideas eg binding of drugs to receptors, Running other machines

' The combination of disk and book certainly add up to a useful elementary statistical package ' *Nature*

Manual vi + 261 pages (spiral bound) ISBN 0 444 80539 7
Disk 5¼" floppy disks (Apple II [3.3 DOS]; Apple IIe – each 3 disks Commodore PET [40 or 80 col display, SD or DD, please specify] – 1 or 2 disks Commodore 64 (also available for Vic 20) – 2 disks IBM personal computer – 2 disks. BBC Microcomputer [40 or 80 track] – 2 or 3 disks.

Mathematics, Biology and Microcomputers by A N Barrett

This book/disk package is aimed at both practitioners and students with an interest in methods for the analysis of biological data, modelling of biological processes and the determination of molecular properties.

The book provides both text and program listings, with detailed documentation and examples, written in BASIC for the Apple II, IBM PC, and BBC microcomputers The programs can easily be transferred to other computers which also run BASIC The disk contains all the programs listed in the book

Chapters cover (*I*) Definitions and explanations of the BASIC statements used in the programs, (*II*) Methods for solving non-linear equations and evaluations of polynomials, and sets of simultaneous linear equations. Matrix computations including formation products and inversion Evaluation of determinants and solutions to sets of equations using Cramer's rule.

(*III*) Determination of molecular properties including computation of bond distances, angles and direction cosines, fitting of lines and planes to specified coordinates Coordinate systems and transformations. Methods for rotation of structures about specified axes including graphics display of results and graphics representation of conic sections Differential geometry and properties of helical structures (*IV*) Fitting of non-linear curves to data including the parabola, hyperbola and exponential functions Numerical methods of integration which include the Trapezium, Simpson's and Three-eighths rule, Calculations of volumes. Statistical methods covering computation of means and standard deviations and evaluation of statistical distributions. Numerical approach to the manipulation of sequence data using prime numbers.

Manual vi + 102 pages (spiral bound)
Disk: 5¼" floppy disk (Apple II [3.3 DOS], [BBC 40 or 80 track]; IBM PC)

Statstream by A Bangham

STATSTREAM has at its heart a library of 76 procedures including data entry, graphing, text-windowing, statistical tests, function-fitting etc. These can be used very simply by:

(1) Calling the helpful menu-driven Statpack, which enables a variety of parametric and non-parametric tests to be done, after a single data entry

(2) Using the 24 demonstration programs designed to teach the user all about statistics and fitting functions to data

(3) Writing straightforward BASIC programs to incorporate the desired procedures

STATSTREAM is usable by, and useful for, everyone from the beginner, new to statistics and computing, to the professional statistician or research worker who wishes to incorporate the elegant STATSTREAM procedures in his own BASIC programs It is also a first class educational tool

STATSTREAM comprises two packed 5 25" floppy disks for the Apple II series (which can be used with one or two drives) (3 3 DOS, min 48K RAM) plus a comprehensive manual

Expert 4 by R. Rivers

An easy-to-use sophisticated disk-based 'Expert System' for the IBM PC at an incredibly low cost

EXPERT4 can be used to create and manipulate a knowledge base, which employs models of human reasoning or 'artifical intelligence' It draws on deductive and fuzzy logic, multidimensional statistics and cognitive psychology. The theory behind EXPERT4 is fully discussed in the documentation which accompanies the disk

EXPERT4 offers a spreadsheet which enables the user to create files or 'domains' each of which is made up of 'elements' which have 'attributes' These have 'attribute values'. For example, in a domain called 'People', 'Jane' is an element. One of her attributes is 'Hair colour'. Jane has brown hair hence 'Brown' is the attribute value

Inferencing facilities in EXPERT4 calculate and display relationships amongst the elements and attributes in terms of similarity and typicality. Any two selected items can be compared in detail for their similarity and differences. An example use would be to assist with diagnosis of a group of diseases with similar symptoms.

Other potential uses of EXPERT4 are manifold, but to give the user an introduction to the program, two completed domains are incorporated on disk as examples

Package includes
Documentation + 5¼" floppy disk for the IBM PC

EUROPEAN JOURNAL OF PHARMACOLOGY

An international journal

Editor
D. DE WIED, *Utrecht, The Netherlands*
Assistant Editors
J. BRUINVELS, *Rotterdam, The Netherlands.* **W. DE JONG,** *Utrecht, The Netherlands.*
D.H.G. VERSTEEG, *Utrecht, The Netherlands.*
Stylistic Editor:
M.-L. DESBARATS-SCHÖNBAUM, *Venhorst, The Netherlands.*

The European Journal of Pharmacology publishes full length papers, short communications and rapid communications concerning animal and human pharmacology.

The European Journal of Pharmacology has been growing steadily since it first appeared in 1967. A truly international journal, it has a broad geographic distribution of authors and subscribers. Its high impact makes it one of the worlds leading pharmacology periodicals. The influx of manuscripts of high scientific quality that is attracted by the European Journal of Pharmacology increases continuously. Both editor and publisher make it their prime concern however to maintain the high standard of quality and speed of publication that were set when the European Journal of Pharmacology was founded. Publication time – from date of acceptance – is about 3 months for full length papers and about 2 months for short communications. The European Journal of Pharmacology also has a Rapid Communication section with a publication time of 4-5 weeks. This section is very popular with authors who have exciting new results and who want to reach a quality readership as fast as possible.

BIOCHIMICA ET BIOPHYSICA ACTA

BBA All the way

Managing Editors:
P. Borst, Amsterdam, The Netherlands
P. Cohen, Dundee, U.K.
K. van Dam, Amsterdam, The Netherlands
L.L.M. van Deenen, Utrecht, The Netherlands (Chairman)
G.K. Radda, Oxford, U.K.
E.C. Slater, Amsterdam, The Netherlands

BBA is one of the world's largest biochemical and biophysical journals.

It publishes papers reporting advances in our knowledge or understanding of any field of biochemistry or biophysics. Descriptions of new methods of value to biochemists or biophysicists are also acceptable if their application is made obvious or a new principle is introduced

Visit the Elsevier stand at IUB, Amsterdam, 26-30 August 1985

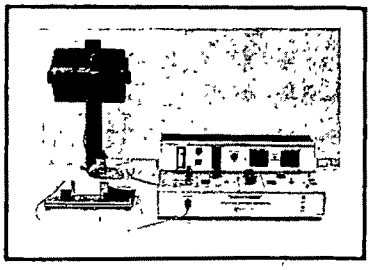
LAB-ANIMAL RESEARCH EQUIPMENT

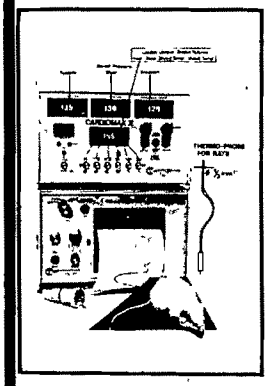
O_2 consumption CO_2 production Respiration Rate

* Continuous measurement of O_2, CO_2 and respiration rate over a 24 hour period in ml/kg of body weight/hour in STP units for 1 to 8 animals
* Prints results every four (4) minutes
* System adaptable to small or large animals
* Continuous airflow through system
* High accuracy, >98% of full measuring range e g typical error ±30 ml oxygen/kg/hour in 3000 ml oxygen/kg/hour range



Apple-Thermometer

"Thermex" interface converts Apple II computer into an automatic printing 16 channel thermometer Accuracy in biological temperature range is 1/10 degree C Variety of rectal, intravenous, implantable probes, etc available Stores results on the floppy disk Data transfer to host computers via RS 232 line possible

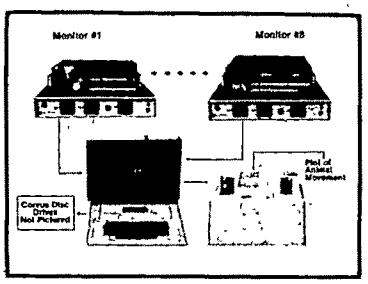


Applications· Prints and measures temperature in multiple animals, pyrogenic activity, blood flow distribution, etc

STARTLE RESPONSE MONITOR TESTS FOUR (4) ANIMALS

System produces surprise stimuli according to a preset program and measures and records the force of the response and the response time Tested and recorded by the system are the force of the startle reflex the reaction time and habitation characteristics The system is also equipped with a stimulus programmer for fully automatic operation The system also includes an automatic printer with its own timer

RATS!!
CARDIAC OUTPUT BY THERMODILUTION



Cardiac Output Computer utilizes 1/3 and 1/2 mm microprobes to measure cardiac output in rats The same instrument works with a variety of other catheters when measuring cardiac output on dogs, horses or humans Dye dilution densitometer available as an option

FEEDING & DRINKING MONITOR

Eight electronic precision scales interfaced to Apple-II computer serve as solid or liquid food consumption sensors

APPLE-II INTERFACE FOR EIGHT (8) ANIMAL ACTIVITY MONITORS

Multiple infrared beams monitor animal activity in the cage Different animal cage sizes are available, e g 15" x 15" or 1m x 1m Apple-II computer computes in periodic intervals the following information total distance traveled, number of rearings, patterns of movements, separate number of stereotypic and ambulatory movements, time spent in each of 16 squares of "Open Field," number of entries into each square, left, right and partial rotations and histograms for each of the above for each animal

ALSO FULL LINE OF:

- ★ **Animal Activity Meters for Rodents, Fish and Insects**
- ★ **"Rota-Rod" System with Electric Shock Enticement for Testing Endurance and Coordination**
- ★ **TV Camera Video Digitizer and Apple-II Computer for Animal Activity and Social Contact Measurements (Automatic!)**
- ★ **Animal Tremor Monitor**
- ★ **Anxio-Meter for Testing Anxiety (according to Vogel principle).**
- ★ **Shuttle Boxes!!! Computerized Reflex Conditioners for Testing Memory and Learning.**

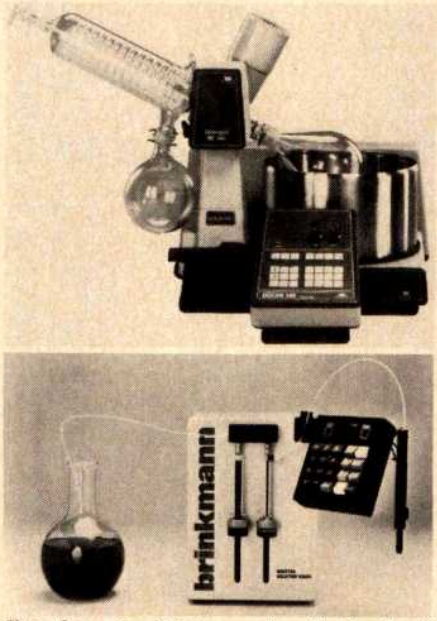
FASEB '85
April 22 - 25,, 1985
Booth 1429

New for FASEB at Anaheim

This year's meeting of the Federation of American Societies for Experimental Biology is at Anaheim, California, opening on 21 April.



• Visitors to Vector Laboratories at Booth 2027 at FASEB can obtain the newest reference and applications list for the Vectastain ABC technique. Citing some 120 of the most recent publications using this ultrasensitive biotin/avidin-based immunoperoxidase system, this list is the third in a series. In addition to providing a compilation of current references, an index of specific applications is included, highlighting pertinent articles using lectins or monoclonal antibodies for immunohistochemistry, enzyme immunoassays, nitrocellulose blotting, DNA hybridizations and electron microscopy.
Reader Service No. 100.

• Two high performance gel filtration columns, Superose 6 HR 10/30 and Superose 12 HR 10/30, have been introduced by Pharmacia. Superose is a unique, cross-linked agarose matrix with high chemical stability over a *p*H range of 1–14. Prepacked in high resolution glass columns (1 × 30 cm), Superose provides high protein and enzymatic recoveries, reproducible separations and long column life. The two products cover a molecular weight range for globular proteins of molecular weights between 1,000 and 5 million.
Reader Service No. 101.

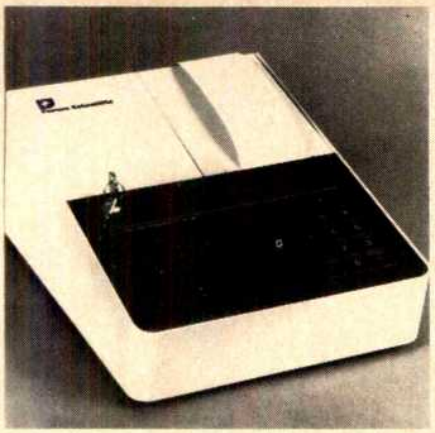
• At the 1985 FASEB show, Bio-Rad Laboratories (Booth 2220) will feature the new Protean II vertical electrophoresis system, a new chromatography system for preparative scale monoclonal antibody purification, and new protein microanalyser. In addition, a variety of chromatography and electrophoresis products of special interest to life scientists are on view. These include: HPHT-MAPS monoclonal antibody purification system for removal of protease, transferrin, albumin, and other contaminating proteins from up to 20 mg of mouse, human, and rat IgG and IgM. The Quick-Check analyser for purification monitoring or protein profiling in 15 min. A protein chromatography system with six complementary chromatographic mechanisms to produce highly purified, active proteins. A data acquisition system with software reintegration, peak naming, and data storage. A fixed-wavelength UV monitor for high sensitivity detection at 280, 254, and 214 nm. A new video densitometer allowing data to be viewed, manipulated, and optimized directly on the video screen. And Immun-Blot, a range of non-isotopic picogram-sensitive blot detection kits.
Reader Service No. 102.

These notes are based on information provided by the manufacturers. Use the reader service card bound inside the journal to obtain further information.

• A new ion-exchange medium that can be packed more quickly and easily than conventional gels, and allows faster flow rates for high-speed protein isolations, is being introduced by Waters Chromatography Division of Millipore Corporation at the FASEB/ASBC meeting. On view on Booths 2633–2641 and 2732–2740, Waters Accell ion-exchange medium is a silica-based chromatography packing featuring a patented copolymerization process that exploits the properties of a rigid separation medium while giving excellent recovery of biological activity. The patented copolymerization process encapsulates the rigid wide-pore silica base to produce low, non-specific binding. The rigid structure permits linear scale-up at all flow rates and pressures, from analytical to preparative to process chromatography, using the same methods and chemistry.
Reader Service No. 103.

Two from the Brinkmann booth, the Buchi rotary evaporator (top) and Brinkmann's digital diluter.

• At Booths 2500–2505, Brinkmann Instruments Co. is showing the new Buchi medium pressure liquid chromatograph for preparative-scale isolations and Brinkmann homogenizers for use in the industrial or biomedical laboratory. Brinkmann is also introducing the new Buchi rotary evaporator Model RE-140, which provides full automatic evaporation via a microprocessor-controlled keyboard. Other products include the Brinkmann digital diluter 9200, featuring continuous selection of volumes from 1 μl to 10 ml and fractional volumes to 0.1 μl.
Reader Service No. 104.



• Pierce Chemical's Diphenyl-8 GC capillary column conditioner is specially purified diphenyltertramethyl-disilazane (DPTMDS). With the higher temperatures and increased sensitivities common to capillary column work, the presence of silanol groups on the stationary phase and column can cause major chromatographic problems. Diphenyl-8 eliminates the symptoms characteristic of residual silanol, prolonging the lifetime of a column by reducing stationary bleed. It deactivates silanol groups on the solid support and acts as a "cleaning agent" for column residues capable of being derivatized.
Reader Service No. 105.

The new Orion cyanide standard.

• Orion Research Incorporated has introduced convenient packs of cyanide standard for use with cyanide electrodes as a calibrating solution. Each reagent pack contains 10 sealed glass ampules, with 50 ml of 100 p.p.m. cyanide standard in each ampule. The standard can be used directly as a 100 p.p.m. calibrating solution or diluted to provide additional dilutions.
Reader Service No. 106.

• The J.T. Baker Chemicals range for lipid screening has been expanded by the addition of two new reagents for cholesterol and triglycerides monitoring. These reagents are formulated according to the CHOD-PAP and GPO-PAP principles respectively. The cholesterol reagent is in a liquid, ready-to-use configuration. The reagent remains stable for up to 12 months and shows linearity up to 20 mmol l^{-1}. The triglycerides reagent is lyophilized and is stable on reconstitution for 3 weeks at 2–8°C. Application sheets for lipid screening reagents are available for a variety of clinical chemistry analysers.
Reader Service No. 107.

● Forma Scientific's new desk-top programmable digital recorder/alarm monitor, the Model 1525, can receive input from, and record any combination of, eight conditioned millivolt signals, such as temperature, per cent CO_2 and O_2, per cent RH, and *p*H. The sensitouch keyboard makes it easy for the user to program the high/low deviation limits for any specified condition. The ink printer records date, time, function, and input number, plus a printout at programmed intervals. Additional printouts are furnished along with audible and visual alarms in the event of a deviation beyond setpoint limits.
Reader Service No. 108.

This catalog will show you why so many people depend on NBS fermentation equipment

- 80 pages of state-of-the-art equipment ranging in size from a 1 liter lab unit to 4000 liter industrial fermentors.
- Digital microprocessor control instrument module for each control loop provides on-off or PID control of agitation, airflow, pressure, foam, dissolved oxygen, temperature, pH and other variables.
- A full range of fermentors and accessories for virtually every laboratory, pilot plant and process use.

Removawell, Dynatech's new plate holder.

● Dynatech Laboratories has added a new Removawell plate holder for Microtiter and Microelisa plates. The plastic disposable Removawell system allows the user to build up an 8 × 12 well plate from strips of wells or from individual wells. Up to 96 wells in total can be held firmly in any configuration. The Removawell holder is designed so that it may be inverted with complete safety when emptying the contents of the wells, regardless of the number of strips or wells present. When assembled with wells, the whole Removawell system has the rigidity and strength of a conventional Microtiter plate, and it may be stacked for easy storage.
Reader Service No. 109.

A splash-proof touch-sensitive keypad controls the WPI pH meters.

● The 700 Series microelectrode amplifiers from World Precision Instruments are designed principally for intracellular recording using fluid filled, high impedance glass microelectrodes. All units feature ultra-stable, gold-plated input probes, low noise, negative capacitance and electrode test capabilities. Applications include intracellular and extracellular potential measurements, impedance and ion selective measurements. Also new from WPI, the HI 8417 and HI8418 microprocessor-based *p*H meters are programmed for easy daily laboratory use. Both meters feature automatic recognition of three different buffers and automatic temperature compensation. Two large LCD displays allow for simultaneous viewing of *p*H (or mV) and temperature. The HI 8418 includes a printer and a numeric keypad. The printer can list not only the *p*H/mV readings, but also the time, date and calibration parameters. The numeric keypad can be used to enter user-defined buffers and intervals for timed printing of data.

FEBS LETTERS

An International journal established for the most rapid possible publication of essentially final short papers in the fields of biochemistry, biophysics and molecular biology

Published by Elsevier Science Publishers B.V.
on behalf of the Federation of European Biochemical Societies

One of the world's leading journals in biochemistry, FEBS Letters is renowned both for its quality of content and speed of production. Bringing together the most important developments in biochemistry, biophysics and molecular biology, FEBS Letters provides an international forum for mini-reviews, research results, commentaries, meeting reports and hypotheses which merit urgent publication.

FEBS Letters' annual **Index of Biochemical Reviews** lists titles, authors and sources of reviews and lectures from a large range of publications in related biological sciences. Entries are indexed under subject headings to serve the research and teaching interests of all biochemists, biophysicists and molecular biologists.

- Direct submission to national editors
- Referees' decision within 3 weeks
- Publication within 6 weeks
- Distribution before cover date
- Fifty free reprints per article
- No submission charges – No page charges

Robotics makes Packard's new sample injector simple to use, with both packed and capillary chromatography columns.

● Packard's "One-Shot Samplers" are injectors for gas chromatography that offer operational simplicity and security. The operator needs only to position a sample vial and press the "start" button to effect injection and begin the analysis. Because the sample volume injected is accurately and reproducibly measured, the use of the external standard (ESTD) method becomes much more attractive; in many cases it can replace the internal standard method (ISTD). Two models are available, the Model 941 can inject into either the front or rear injection port. The desired port is software selectable, this feature facilitates the automation of identification and duplication of analyses. Two different analyses can therefore be run. The Model 940 is similar but allows injection only into the injection port above which it is mounted. Both models are suitable for packed and capillary columns.
Reader Service No. 111.

● New England Biolabs have developed an *in vitro* method for creating novel DNA cleavage specificities. This simple procedure involves the methylation of the DNA with a site-specific methylase followed by cleavage of the DNA with a restriction endonuclease whose recognition sequence overlaps that of the methylase. Only a specific subset of the restriction endonuclease sites will be cleaved (see *Nucleic Acids Res.* **5**, 5165-5173; *Biotechniques* **2**, 218-222). The latest additions to New England Biolabs' list of over 90 restriction endonucleases include the following: *Bsm*I (GAATGCN/); *Fsp*I (TGC/GCA) (= *Mst*I); *Nhe*I (G/CTAGC); *Ssp*I (AAT/ATT); *Spe*I (A/CTAGT); and *Sty*I (C/C(A,T) (A,T)GG). New DNA methylases include; M.*Hph*I (TCACC); M.*BamH*I (GGATCC); M.*Hae*III (GGCC); and 'dam' (GATC). New M13 cloning vectors from NEB are: M13mp18 RF I DNA and M13mp19 RF I DNA.
Reader Service No. 112.

● The new polymer-based columns from Hamilton Co. of Reno, New York, are intended to extend the limits of HPLC and ion chromatography. Hamilton polymeric reversed-phase (PRP) resins accept eluents between *p*H 1 and 13, whereas silica tolerates only *p*H 2 to 8. For HPLC, PRP-1 columns separate virtually all classes of compounds, with no need for ion-pairing reagents. Because PRP particles are chemically identical from surface to centre, selectivity variations common to silica cannot occur. Columns are available with different particle sizes (5 and 10 micrometres) and in a variety of lengths (15, 25 and 30.5 cm) to meet most chromatographic needs. Low-cost bulk packing is available for preparative-scale separations. For ion chromatography, the PRP-X100 achieves rapid separation of the common anions. Unlike silica, the *p*H tolerance of PRP-based resins permits high-resolution separations of cyanide, sulphide, silicate, borate, and other anions requiring high-*p*H mobile phases. The 10-micrometre PRP-X100 columns are compatible with existing HPLC and ion chromatography equipment, and are available in 10, 15, and 25 cm lengths.

On the Vangard booth, the latest Sartorius filter holder.

● A multipurpose filter holder, manufactured by Sartorius GmbH, is now available in the United States from Vangard International. Applicable for vacuum or pressure filtration, the multipurpose filter holder is integrally moulded of clear polycarbonate for strength and to ensure repeated autoclavability at 121°C steam. Applications for the filter holder include clarification and/or sterilization of liquids, and microbial analysis such as sterility testing.

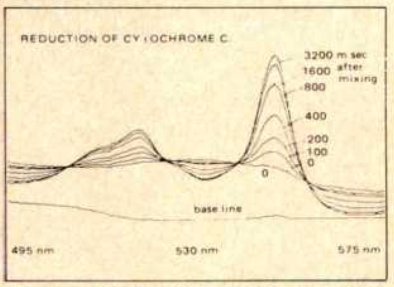
UNION GIKEN

First choice for

STOPPED FLOW



reaction analysis

Union Giken apparatus achieves a dead time as short as ½ millisecond for measurement of fast reactions. Gas pressure is directly applied to the surface of the reactants in each reservoir, mixing and flow being controlled from the end of the system by a high-response stop valve. The RA-401 STOPPED FLOW SPECTROMETER is the ideal match for fast reactions.

The RA-451 DATA PROCESSOR generates a simulated reaction curve from the measured results and automatically calculates the rate constant.

The RA-415 RAPID SCAN ATTACHMENT monitors the change in absorption spectrum during the reaction.

Other attachments are available for T-jump, P-jump, fluorescence and flash photolysis.

● The K531 Dako PAPA kit System 20 is designed as a research tool for the demonstration of myelin basic protein (MBP) using the peroxidase anti-peroxidase staining technique. The primary antibody in this kit represents a pool of optimal antisera selected from many immunized rabbits. This polyclonal antibody shows very good reactivity with the antigen even under the adverse conditions encountered after tissue is fixed in formalin. In addition to 7 ml of primary antibody, a comprehensive set of reagents is provided in working dilutions. Five control slides for the initial use of this kit are also included. K531 has a minimum capability of twenty tests. This routine system comes with simple instructions for those with limited or no previous experience with the immunoperoxidase technique.

New Mini Evaporator/ Sputter Coater

The Mini Evaporator with Big System Performance

Balzers MED 010 turbo pumped high vacuum mini coater both evaporates and sputters high-quality, uniform thin metal films on samples up to four inches in diameter - fast and efficiently.

This 120-volt bench-top unit has all pumps and control units built-in. With quick, one-button pumpdown to 10^{-7} Torr, the MED 010 is a cost effective alternative to large bell jar systems for small coating tasks or thin film research, or SEM and TEM sample preparation.

Cherry, pine and clove scents overcome less attractive odours—Odo-Clave from Bel-Art.

● The unpleasant odours emitted during autoclaving can be countered using Bel-Art Products' Odo-Clave deodorant disks. Two new scents have been introduced, pine and cherry. Each 1½-inch disk is impregnated with a special heat released deodorant specifically designed to be activated when exposed to the high temperatures of the autoclave. The pine and cherry scents, like the original clove scent, all serve to neutralize, not mask unpleasant odours.

The Cavro sample processor and diluter gain flexibility with a new hand-held probe.

● Cavro Scientific Instruments, Inc. has introduced a disposable-tip hand probe for use with their automated IQ 190 sample processor and Model 1500 pipettor/dilutor. The hand probe ensures zero cross-contamination and is ideally suited for applications using enzymes, radioisotopes or biohazardous materials. The hand probe can be used for liquid transfer, or can pipette and dilute in a single operation. Multiple dilutions (serial dilutions) can also be performed using a single tip. Aspirations up to 75-microlitres can be performed using 200-microlitre disposable tips. Dilution ratios are easily controlled by adjusting the dispense volumes of the two syringe pumps on the instrument. The natural grip, weight and angle of the hand probe are optimized for ease of use and to minimize fatigue. Because the hand probe is used with an automated pipetter/diluter, variable results normally associated with extended use and operator-to-operator variations are eliminated.

● Streptavidin and biotin are being used increasingly as bridging reagents for detection of proteins, cells and nucleic acids, as well as isolation of cells and proteins. Streptavidin exhibits the same high biotin-binding capability as does egg white avidin, but with much less nonspecific binding. The result is high specificity and sensitivity with very low levels of background. Bethesda Research Laboratories has compiled a comprehensive illustrated guide, "Streptavidin: Applications in Detection of Proteins, Cells and DNA". This free 12-page booklet begins with an explanation of the powerful and versatile streptavidin/biotin interaction. The guide details many applications of streptavidin/biotin methodology, including: detection of proteins by immunoassay and immunoblotting techniques; detection of cells by light, fluorescence and electron microscopy; nonradioactive detection of DNA at 2-5 picogram levels; isolation of cells by fluorescence activated cell sorter; and isolation of proteins by immobilized streptavidin.

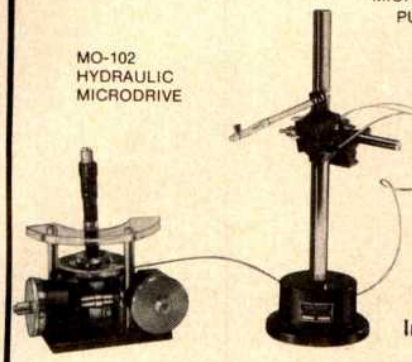
The Hacker slide-stainer.



● For histology and cytology, the Hacker Instruments continuous slide stainer features linear operation through 18 stations. Immersion time is variable between 6 and 12 min, with a drain time of 3-60 s. The holders transport 22 slides each through the stations, and up to 5 holders store before and after processing. Holders may be agitated and stations 2-17 are plumbed for running water. Throughput is up to 600 slides per hour at a dwell time of 2 min per bath. All conventional and special stains and rinses can be used to give uniform standardized slides.

KRYOPRESERVATION

THE ULTIMATE IN CONTROLLED RATE FREEZING

The Kryo 10 from Planer is probably the most advanced programmable freezer in the world.

Microprocessor controlled, Kryo 10 incorporates a top loading chamber, side access panels, integral recorder and has exceptionally wide operating ranges allowing for very fast or slow uniform freezing.

Typical applications include

* Human embryo (I.V.F.)
* Bone marrow for transplantation
* Tissue culture cells
* Platelets as a bank for transfusion into patients
* Spermatazoa for animal husbandry
* Embryos for maintenance of genetically pure stock
* Food cultures

Electroblotting is one application of the Hoefer PS 250 power supply.

● The PS 250, Hoefer's new 250-volt power supply, delivers the high current needed for fast, effective electro-transfers. It supplies currents as high as 2.5 amps. It also delivers ample voltage and current for running multiple vertical or submarine slab gels of miniature or standard size. The PS 250 has six sets of output jacks wired in parallel so that current may be drawn by as many as six units. It can operate in either constant current or constant voltage modes, with automatic crossover between modes. Full voltage and current are available for a total output of 625 watts. The PS 250 is particularly useful for electroblotting and rapid screening.
Reader Service No. 122.

● The Biomedical Technologies, Inc. range of immunoassay kits now includes RIA kits for both cyclic AMP and cyclic GMP. Each kit utilizes highly specific primary antibodies preconjugated with a second antibody to minimize nonspecific binding and to eliminate a second incubation step. The assay sensitivity for the cyclic AMP kit is 0.1 picomoles per tube and 0.005 picomoles per tube for acetylated samples. For cyclic GMP, sensitivity is 0.2 picomoles per tube and 0.005 picomoles per tube for acetylated samples. The protocol includes only three pipetting steps and one incubation and generates a visible precipitate. All necessary reagents including a true nonspecific binding reagent and acetylation reagents are included in each 200-tube kit. The kits have a shelf life of ten weeks at 4°C.

The latest Cahn instruments interface to IBM's small computer.

● The power of the IBM PC can now be used to analyse data gathered with the Thermogravimetric System 113 and Recording Electrobalances made by Cahn Instruments, Inc. The Cahn IBM Data Interface plugs quickly into the IBM PC allowing users to select data input parameters and output options. Weight and temperature data are converted to digital signals via the interface, which works with a flexible, user-friendly software package. Menu-driven commands provide choices for data gathering and output via printer or plotter. During the sample run, actual weight and temperature data are displayed in real time on the IBM monitor. A two-colour plotting routine that operates with the Hewlett Packard 7470A plotter offers multi-plot capability with graphics expansion and contraction features. Software is written in IBM basic.

Up to four solvents can be blended by Perkin Elmer's delivery system.

● Delivery systems in which up to four solvents may be blended can be used in the analysis of a wider range of samples than two or three solvent systems. This versatility is characteristic of Perkin-Elmer's four-solvent delivery system for high performance liquid chromatography, the new Series 400 and the proven Series 4. The Series 400 can be used for all types of HPLC — microbore, analytical, high speed and semipreparative. Dedicated single-function command keys simplify operation of the Series 400, including its multi-step multi-method programming. A method consists of up to ten programming steps. Nine user-defined methods can be stored and all stored data is protected by battery backup. Low conversion volumes allow solvent compositions to be changed in seconds. The Series 400 pump can be programmed for isocratic or gradient analysis with up to four solvents. Automatic compressibility compensation and positive volume proportioning, which automatically corrects for solvent mixing effects, ensure excellent reproducibility.

Cardiac output determination — the Columbus 400.

● The New Columbus Instruments Model 400 thermodilution micro-injector, on Booth 1429 at FASEB, has the capacity to inject rapidly 100 microlitres to 10ml of cold indicator for cardiac output determination. It is driven by electric motor and therefore does not require compressed air or CO_2 cartridges. It automatically refills itself with fresh supply of injectate through the two-way valve and volume of injectate is adjustable in steps by change of glass syringe and continuously via a precise adjustable stop.
Reader Service No. 127.

● FMC Bioproducts' SeaKem genetic technology grade agarose is prepared for use with very high molecular weight DNA, 1kb to native. SeaKem GTG agarose meets rigorous specifications for low inhibition in genetic studies and biotechnology research. High gel strength means that low concentrations can be used (0.1-1.5%).

nature

NATURE VOL 314 25 APRIL 1985

Are the philistines in charge?

A curious argument in the London Times *suggests that those who would make the British universities more productive do not understand what science is about.*

SIR Douglas Hague, the chairman of the British research council charged with supporting social science, has been a valuable influence among the grander councils of the research establishment in the past two years. He has rightly raised awkward questions (still not answered) about the management of the British government's support for civil science, in particular asking whether the Advisory Board for the Research Councils is constituted in a way that will allow it to do the job intended for it. Sir Douglas is also a member of the committee looking into the future of British membership of the European centre for high-energy physics at Genèva, and is widely expected to be found among those who advocate pulling out when the report appears in a few weeks. Earlier this month, he argued (in *The Times*) the case for stronger links between industry and academic science, and in passing made a side-swipe at the academics of the University of Oxford for having denied the Prime Minister, Mrs Margaret Thatcher, an honorary degree, which is also fair (see *Nature* 7 February). If Sir Douglas Hague is a philistine, he is both measured and moderate in that role, more a gadfly than a real philistine.

The same cannot unfortunately be said for his supporters, especially Dr K.A. Harrap, who described himself (*The Times*, 19 April) as having been, until recently "head of marketing" at the Natural Environment Research Council. His premise is that British science, which is "fit, able and creative", has for too long been dependent on only the government for support. Dr Harrap continues by acknowledging that there has now been a change of circumstances, but that it will not suffice that the scientific community should simply cry "foul". So, he concludes, scientists must "publicly emphasise their wealth-generating capability" not only in the public interest but so as to "demonstrate to the public and its government that science is good value". For good measure, he asks that "publicly funded scientists themselves" must demonstrate that they can turn "intellectual strength" into wealth, and that if, in the process, the "cutting-edge of blue-skies research becomes somewhat blunted so be it". The meaning of the phrase is probably clear even if its imagery is a little confusing.

The reasons why this argument is false, and dangerously so, deserve to be widely understood, for there is every reason to suppose that the same mistaken conclusions account for much of the British government's indifference to the damage it has been doing to the scientific enterprise during the past five years. (Dr Harrap, for that reason, should not think he has been unfairly singled out for criticism; indeed, he might even claim credit for having made public, perhaps unwittingly, a line of argument that should be better known.) The issue is the balance that should be struck between basic and applied research in a country such as Britain which has, for far too long, supposed that the economic problems that have afflicted it do not exist, and the question of the role of basic research when wealth-creation, in Dr Harrap's language, is the goal.

No harm is done by conceding Dr Harrap's premise, and its antecedents. British research support has been unduly monolithic. British academics have been too uniformly inclined to measure their success in exclusively academic terms. It might be added that much of the reason why British academic research has been industrially disappointing comes from the unwillingness of government departments and industrial companies in Britain to credit British academics with being capable of generating valuable innovations. If it were otherwise, the defence and industry departments would be more than the minuscule sources of research support they are at present, while the handful of British universities that have been glad to welcome industrial support would have prospered to the envy of the others. It serves no purpose for anybody to lay Britain's economic poverty at the doors of the academics.

It is also possible to concede the continuation of the argument, that crying foul on a change of circumstances serves no purpose. The British academic community as a whole, not just the scientific part of it, was far too slow to recognize the threats to its integrity when these first began to appear more than a decade ago. Not surprisingly, the pretence that there was nothing wrong has now been overtaken by a sense that everything has turned to dust and ashes, and there is nothing to be done. In its own interests, the academic community in Britain should accept the Hague/Harrap argument that the academic community should recognize the serious character of the government's economic problems, show willing in helping solve them and be more imaginative in exerting itself in its own interests.

So how, when so much is conceded, can the Harrap line be mistaken? Because it makes the false assumption that prescriptions that can fairly be held to apply to the scientific community should apply to all scientists individually. And because it goes on to conclude that it would be possible for a country such as Britain, seeking to make its way in a more competitive world by harnessing all "publicly funded" researchers to the same goal of wealth creation, to abandon imaginative research with no foreseeable application without quickly running into trouble. Both conclusions are false. Present circumstances probably require (and will certainly drive) more academics to look for industrial projects on which to work, but why should the same recipe apply to each and all of them? And the second, that imaginative research is "for the time being" dispensable, is untenable, at least so long as it is intended that the education of students should be more than mere paper and that the applied research of future decades has some grist to feed its mill.

This is where the philistines go wrong. They forget, or they choose to overlook, that the scientific enterprise is all of a piece, and that while the balance between the different parts of it can be changed, the belief that some parts of it can be dispensed with altogether is an error born chiefly of ignorance. But what about Japan? Sir Douglas Hague's original protest raised this question but without conviction. It is, of course, a red herring, as the Japanese now seeking to legislate for more creativity within their system would be the first to confirm. Japan has done well, over the years, by also adapting technology from elsewhere to modern market needs, often the needs of markets elsewhere. But even Japan is not sure of sustaining its technological growth beyond the point reached by others with its own unembellished basic research. And while the Hagues of this world may understand the subtlety of the problem, they should choose their words more carefully so as not to give a licence to those who do not or prefer not to understand. In Britain just now, there are too many philistines of that kind roaming the streets and even the corridors of Whitehall. □

Dollar fragility

Why must researchers worry about the dollar? Because research funds may vanish.

LAST week's predicted further fall in the value of the US dollar is not the first this year, and will not be the last. Last month's tumble was attributed to the financial difficulties of several Ohio semi-banks and last week's to the estimate of slower US growth this year (1.8 per cent) than last (6.5 per cent), but these are occasions, not causes. The fragility of the dollar is a consequence of the US government's huge budget deficit and of the certainty that even if the administration and the Congress agree that it should be cut, the effects cannot appear until the beginning of the next financial year in October. Can the world wait that long?

The fear that time is running out is barely concealed. Even finance ministers at last week's meeting of the International Monetary Fund in Washington allowed their determination not to be seen to rock the boat to be compromised by anxiety. What worries them is that the US administration is now a tight box. Either it will have to cover its deficit by increasing interest rates still further or give up trying, print money instead and put up with the inflation that would follow. The explanation that last week's fall was triggered by people's calculations that the administration would now try to stimulate the economy by reducing interest rates is not to be taken seriously, for cost-free options have gone the way of the free lunch. Nor does it make sense to ask, as some do, that other industrialized nations should assume the burden of stimulating economic growth by government policy, for inflation-free growth outside the United States will be possible only when the flow of funds to the United States in the past few years has been substantially redirected, adding to the problems of the dollar.

This is why talk of monetary reform has become fashionable again. Even Mr James Baker, the new Secretary of the US Treasury, is in favour. The trouble is that nobody knows what should be done. Things have changed a lot since John Maynard Keynes went off to Bretton Woods in 1943 and drafted the monetary rules by which the world lived for the succeeding thirty years. The essence of Keynes's recipe was a blend of currency stability by means of declared exchange rates and a mechanism for the supply of credit, through the International Monetary Fund. One change since then is that there is now almost a surplus of international credit, much of it stimulated by the steep increase of the price of oil in the 1970s, whose movement is uncontrolled and hard to anticipate. Another is that the financial markets have become technically more efficient and sophisticated than Keynes could have imagined. The needs now are to find ways of giving currencies a measure of stability even when they are traded freely, and to shield developing countries from the damage they can suffer from these processes. After a decade in which most governments have been indifferent to these needs, it is gratifying that most governments now accept the need for reform.

Part of the trouble with the present system is that huge sums of money can slop about within it, in pursuit of the marginally different interest rates on offer at different places. The volatility of the system would be much reduced if only governments would agree to limit the proportion of their borrowing that consists of short-term debt. (In a typical week, the US Treasury now raises between $10,000 million and $20,000 million of short-term money, most of it to cover maturing debts and not the underlying deficit.) Self-denial like this by governments would not be very different from what governments require of their commercial banks. In the process of reform, Europe has a particular responsibility (and opportunity). A more thorough coordination of European arrangements for coordinating monetary policy would increase the inertia of the system without, in the long run, biasing the ways in which money moves. The European Monetary System, which ties together major European currencies (but not sterling), is a start but an imperfect one, while it will be decades before the European accounting unit (called the ECU) will become a currency. One objective, now, should be to set up a pan-European central bank with the funds and the independence to be effective.

The monetary problems of the developing countries are more intractable, partly because most governments do not accept the logic of the need to act. Why else would so many rich countries still restrict the import of simple manufactures, but not the raw materials on which many developing countries are too dependent for what passes for prosperity? While restraints like this persist nobody should be surprised that developing countries cannot easily attract the funds they need for development (although they are also, often, their own worst enemies by the political hazards with which they confront potential investors). In this sense, last week's meeting of the International Monetary Fund at Washington must know that its talk of insuring private companies' investments in developing countries, by some mechanism yet to be devised, is a palliative , not a solution. The monetary problems of the poor will be solved permanently only when the industrialized world accepts that they have a right to earn their way out of trouble, and is then prepared to help them do so through agencies such as the World Bank, designed for just this purpose. □

Tarnished initiative

The offer to allies of a share of the US defence budget has been indelicately handled.

THE second subject (monetary policy is the first) that will preoccupy the summit meeting of the major powers due next month is that of what should be done about the US plan to build a defence against ballistic missiles, sometimes known as the Strategic Defense Initiative, but which is otherwise star wars. European governments represented at the meeting will be in a fix. Sceptical of the scheme from the outset on the grounds that it would probably be ineffectual and that the development of such a system would cause more international trouble than even success would be worth, and in some cases fearful that success would lead to a US abandonment of Europe, they have been tempted against their better judgement into collaborating with the planned technical developments (see p.660). For many, the principle seems to be that they will then at least know what is going on.

The US government's position is not very different. There was nothing in President Reagan's speech in March 1983 to suggest that star wars was intended to be collaborative venture, or even that the governments of Western Europe could fail to share the president's own sense of wonder at the supposed benefits of a world (or part of it) blessed with immunity from nuclear attack. In the event, the scepticism of European governments blended with the administration's own sense that there may be safety in numbers in the trying months ahead have combined to persuade the United States that collaboration would be worthwhile. The reluctance, or surprise with which the administration has come to this view is clear from the letter from Mr Caspar Weinberger to the political heads of potentially collaborating countries last month: in these days of word processor, it is surely needlessly offensive to send what seems to be a circular letter, in which recipients are invited to render "your nation's" response.

As things stand, there is no way telling what European states should say. The offer of collaboration is too innocent of detail to be appraised. The governments that fear that collaboration will be a formal matter only may be right. Those who hope to make money out of the scheme may, alternatively, hit the jackpot. But nobody can know for sure — and certainly not within the 60 days first specified in Mr Weinberger's letter. But the simple rule should be this: if collaboration is genuinely intended, it should be complete, and should allow collaborating European partners to influence not merely the development of star wars technology but also the use that is made if it. And otherwise, if collaboration is offered on terms that are less than full, it should be politely declined on the grounds that it cannot fail to be comprising. That is one version, but that there are others which are less polite is what some governments will be saying in Bonn. □

AIDS progress

Synthetic vaccine only a distant prospect

Atlanta, Georgia

THE virus responsible for acquired immune deficiency syndrome (AIDS) in humans may have entered the population recently by transmission from monkeys, according to a study of African green monkeys by Max Essex of Harvard University. Essex has found that apparently healthy monkeys show strong antibody recognition of STLV-III, a virus associated with immune deficiency disease in rhesus macaques which has many similarities with human AIDS virus. A simian origin for the virus would be consistent with new data suggesting that AIDS may have been present in humans of central Africa since before 1973.

Essex reported his findings here at the first international conference on AIDS, attended by two thousand researchers from 26 countries. The meeting was sponsored by the US Department of Health and Human Services and the World Health Organization, among others. The availability of two different primate models of AIDS, one with disease and one without, should be invaluable for development of an AIDS vaccine: comparisons between viruses might indicate those conserved regions that might be most usefully imitated in a synthetic vaccine produced by genetic engineering, so avoiding the problems caused by antigenic variability.

A vaccine that would prime the immune system to deal with the AIDS virus is one of the best hopes for dealing with the disease; it seems unlikely that a treatment will be found that will eradicate the infection once it becomes established in an individual, where DNA copies of the virus are incorporated into the host's own DNA. James Curran, head of the AIDS task force at the Center for Disease Control (CDC), said that if a vaccine became available it might be necessary to vaccinate all US citizens, starting first with those in high risk groups who at present show no evidence of infection. A vaccine is still several years away, however.

The latest data on the spread of AIDS in the United States are grim but unsurprising. By last week 9,608 cases had been diagnosed of which 4,712 have been fatal. Estimates of the number of US citizens who have already been infected with the AIDS virus, as indicated by the presence of serum antibodies, range from 0.5 to 1.0 million; more than 10 per cent of these are likely to develop the disease over the next five years, even if all further transmission of the virus stops immediately. The doubling period for the number of reported cases in the United States has increased slightly, but is still around 8–9 months. Principal conclusions from the conference have been reported to the US Department of Health and Human Services, and a separate report is being prepared for the World Health Organization.

New estimates have been made of the latency period between infection and the onset of disease symptoms, and it seems that the mean latency may be five years or even longer; this suggests that many people in high risk groups may already have been infected but are clinically unaware of the fact.

Between 70 and 90 per cent of haemophiliacs who receive regular infusions of factor VIII concentrate have detectable serum antibodies to the AIDS virus, and some data suggest that more than five per cent of these are likely to develop AIDS, with a further number developing "lesser AIDS" — AIDS-like symptoms that nevertheless fall outside CDC's definition of AIDS (Elaine Eyster, Pennsylvania State University School of Medicine). Estimates of the proportion of people with antibodies who will develop the disease are likely to go on increasing. Among one group of New York promiscuous homosexuals, the proportion of those with antibody that have developed AIDS is as high as 20 per cent (J Goedert, National Cancer Institute); it is not yet clear whether this high figure is due to some complicating lifestyle factor or whether it is because the virus has been present for longer in that group.

Very preliminary data from wives of haemophiliacs suggest that the AIDS virus is transmitted heterosexually by repeated contacts from male to female (J. Goedert, National Cancer Institute). A claim for female to male heterosexual transmission from prostitutes was also made (R. Redfield, Walter Reed Army Medical Center), though these data are also equivocal.

Some modestly encouraging results for treatment of AIDS with anti-viral drugs were reported, although none amounted to a major breakthrough. It is now apparent that neurological symptoms such as dementia are present in high proportion of AIDS patients, often associated with encephalitis.

US Secretary of Health and Human Services Margaret Heckler told the conference that AIDS is the chief health priority of the administration, but her speech, which studiously avoided mentioning the principal risk group, male homosexuals, did nothing to soothe the anger of homosexual activists and AIDS patients attending the conference.

Robert Gallo of the National Institutes of Health, who first isolated the virus known as HTLV-III, made a plea for less petty nationalism in the competition between research groups in different countries. Gallo's plea was not immediately effective: the AIDS virus continues to be referred to by at least three different names depending on the affiliation of the speaker, despite agreement that the virus isolated by different groups is basically the same, and despite an informal agreement to call the virus HTLV-III/LAV (or LAV/HTLV-III) in recognition of the work of the French group under Luc Montagnier at Institut Pasteur in Paris. The name issue is to be tackled later this year by the International Committee on Virus Nomenclature. Gallo also took many by surprise by calling for an end to the cult of the instant media authority.

All the blood banks in the United States are now screening donated blood for AIDS virus using enzyme-linked immunosorbent assay test kits manufactured by commercial companies, but implementing the tests has not been without its problems. According to Gerald Sandler of the American Red Cross, an anomalously high proportion of samples tested with the Abbott Laboratories' kit produced evidence of AIDS antibody on first testing in some areas of the country, although the proportion of repeatedly reactive samples was close to the expected 0.2 per cent. Samples that produce positive results on two subsequent tests are confirmed by Western blotting, but it is apparently impractical to carry out Western blots on all samples that produce a positive result just once.

It is also becoming clear that after infection by the AIDS virus, several weeks or months may pass before antibodies reach easily detected levels; any test that looks just for antibodies can therefore be at best an imperfect protection for blood banks. In Britain, initial investigations of the Abbott test have produced disappointing results, and it seems most likely that Britain will develop its own test for blood banks rather than importing US products; price is also a factor.

There is still no agreement on whether US donors who show clear presence of antibody that is confirmed by Western blot should be told of the results of the test. The American Red Cross says it is still reviewing options, and organizations in different states are following different paths. California has adopted a moratorium on conveying test results to donors until alternative testing centres are established where people can be tested for antibody without giving blood.

The fear is that as long as testing is available only at blood collection centres, people in high risk groups will be attracted to offer their blood in order be tested: questionnaires indicate that most people in high risk groups do want to knows whether they have circulating antibody, despite the uncertain prognosis. Some federal funds are likely to be made available to establish several hundred alternative test centres, though the amount is still being argued.

Star wars

Israel attracted by spin-off

Rehovot

ISRAEL is almost certain to accept the invitation it has received from the United States to participate in the Strategic Defense Initiative ("star wars") research programme.

If the government does so, it will enjoy the support of most of the scientific community, which hopes that the project will provide research funds that are no longer available from other sources and also create positions for young scientists who might otherwise leave the country.

Professor Josef Singer, president of the Haifa Technion and an aeronautical engineer who has himself done defence research, supports Israeli participation but warns his colleagues that they should not expect the United States "to spend billions of dollars and to engage thousands of scientists and engineers".

Singer points out that the US armed forces have already spent millions of dollars over the past 30 years in support of research projects at institutes in Israel. "And", he says, "while Israel stands to gain more in resources and know-how, it also has a contribution to make. Otherwise, it would not have been invited to participate." He expects there to be benefits for Israel in the high-technology industries. And off the record, other Israeli scientists say that star wars research, although primarily aimed at finding a way to bring down Soviet ballistic missiles, may help to improve Israel's military potential closer to Earth. Specifically, they speculate about the development of an innovative deterrent that might compensate for the fact that shortage of money and manpower make it difficult for Israel to match the military build-up of its Arab adversaries.

A dissenting opinion comes from Professor Giora Shaviv, an expert on space research at the Haifa Technion, who dismisses the invitation to Israel as a propaganda move and says that Israeli researchers "have no real role to play" in the star wars scheme. A small number of politicians and academics have raised the subject of the moral and political implications of Israel's participation in the US programme.

Meir Stiglitz, who teaches a course on nuclear weapons at the Hebrew University's International Relations Department, claims that Israeli leaders are so blinded by the immediate benefits of cooperation with the United States in this sphere that they overlook the potential long-range dangers. As he sees it, these include the possibility that Israel may become a "desirable and legitimate" target for Soviet nuclear missiles, and might be attacked in order "to send a message" to the United States. **Nechemia Meyers**

Star wars

France rallies European forces

THE French government is determined to shake Europe awake, and to encourage all the nations of Europe to take a great leap forward in science and technology, by creating a new European research organization with considerable powers and funds, dubbed "Eureka". Or it may be that the French government is scared stiff of participation in the US Strategic Defense Initiative (SDI, or star wars) because it feels this might suck France dry of some of its best weapons technolgies, and wishes to form a common European industrial and research front. Eureka would be that front.

Which is the truer picture of French intentions? Probably both are true, which has made it a little difficult for Western European foreign ministers to respond to an urgent letter, proposing the flexible and rapid creation of Eureka, addressed to them last week by their French opposite number, M. Roland Dumas.

In the letter, Dumas says that Eureka (which in a rare French linguistic concession he gives the English name "European Research Coordination Agency") would set up major programmes half-funded by Eureka and half by industry in optronics, new materials, high-powered lasers, artificial intelligence, high-speed and ultra-miniaturized microelectronics and space. Any European state should be able to join in any programme, Dumas suggests, leading to a "variable geometry" Europe for research. But what research? Dumas' shopping list is remarkably similar to one that might be drawn up by SDI, rather than the new technologies in general (where is biotechnology, for example?), but the letter does not mention SDI by name.

Nevertheless, French interest in creating what the Prime Minister, M. Laurent Fabius, calls "a European area for research" is well known, and long pre-dates interest in SDI. France has doubled its government civil research spending since President Mitterrand came to power in 1981, but now realizes that France cannot go it alone against the United States and Japan. Thus Pierre Papon, director-general of the principal French research council, the Centre National de la Recherche Scientifique (CNRS), which has 10,000 researchers, made a detailed tour of Europe last year seeking bilateral research agreements, and the present research minister, ex-president of the French space agency the Centre National d'Etudes Spatiales (CNES), has also shown himself a dedicated European.

But these individuals and others in the French science political scene may be getting impatient at the pace of European integration in science and technology. ESPRIT, the European programme of research in information technology, flagship of the European Economic Community (EEC) programme in integrated "pre-competitive" research, has been extremely slow to spend real cash, and for the moment can claim only that it has brought a few European companies to the same table. The only really working institutions of any size seem to be the European Organization for Nuclear Research, CERN, which has only a moderate economic impact, the European Space Agency (ESA) of which Curien has been chairman, JET (the European fusion experiment, with impact only far in the future) and the European Airbus.

France wants much more, and earlier this month Jacques Delors, the new French president of the European Commission (the EEC bureaucracy), tried to provide it. In a written presentation, he asked European ministers at a summit meeting to double EEC research spending from its present three per cent of the Brussels budget to six per cent, and he linked the increase with the need for Europe to respond to SDI. Ministers — who at present in the 10-nation EEC must agree any proposal unanimously — threw out both ideas. Many states were, it seems, prepared to increase the research budget, but by nothing like the factor of two, and the SDI link was described by some participants as "half-baked", rushed and ill-prepared. There seems to have been no collaboration between Delors and the French government over the issue, and it may be that Delors had had wind of the Eureka proposal and wished to put up an EEC stake, fearing the likely weakening effect of Eureka on Commission power in research.

Nevertheless, Delors was unsuccessful, and now Dumas has proposed Eureka, determined, it seems, to see something happen for European research. But the announcement of his initiative last week in Paris was not made through the usual channel, the Wednesday council of ministers meeting, but direct from the ministry of foreign affairs itself. Staff of CNRS "read about Eureka in the press". There seems to have been "a little problem of communication" between the foreign ministry and the research council, though Pierre Papon "has since become involved in discussions".

Moreover, the links with defence have clearly become stronger, as Dumas' letter to foreign ministers was delivered a few days in advance of this week's meeting of the Western European Union, a recently-revived forum in which seven of the major European states discuss defence matters. The letter is intended for discussion "on the margins" of the meeting. Dumas will no doubt be expressing concern about French industry, in which spending on armaments has become the principal component. Last year, for the first time, France exported more arms to the United States than it imported from that country. And

recently a number of French companies including Thomson, the nationalized electronics company, have gone well into the black through trade in armaments, much of it to the Middle East. Often this trade relies on high technology weapons, such as Exocet, the missile which was so dangerous to British ships in the Falklands conflict. France does not seek a one-way drain of expertise or experts to the United States through premature involvement in the star wars programme.

Thus Dumas is concerned by the position of Britain, where foreign minister Sir Geoffrey Howe has criticized SDI so strongly (on strategic grounds) that France fears Britain may not participate at all. Dumas is slightly happier with West Germany, with which France has increasingly been developing a special relationship in Europe. There, Chancellor Kohl has expressed full support for Eureka but has gone further than the French by agreeing separately with the United States to take part in the SDI research programme. Kohl will send a team of negotiators to Washington to discuss the matter, he has told the Bundestag.

Some united participation in SDI is what France wishes to see. And it is even preparing its public SDI is "star peace", not "star wars", defence minister Charles Hernu claimed on French radio last week. "And France must have its place in this star peace", he proclaimed.

Star wars

US pressure on Japan

Tokyo

THE US Strategic Defense Initiative ("star wars") seems to have found a fan in Japan's Prime Minister Yasuhiro Nakasone, who has been extolling its virtues in recent Diet speeches after his meeting with President Ronald Reagan in Los Angeles earlier this year. Pressure for Japan to make its support official is being kept up by a series of visits from US experts. The real issue, however, is how far Japan is prepared to move from its pacifist constitution, which prevents participation in collective military efforts.

At the end of last month, US Defense Secretary Caspar Weinberger formally asked Japan as well as other US allies to inform the United States within 60 days whether it is willing to participate in the US research programme for the Strategic Defense Initiative (SDI). Weinberger's request was immediately followed up by a series of visits to Japan by US military experts and a delegation from the North Atlantic Treaty Organization (NATO) to "explain" SDI and to look for areas of cooperation.

Although the 60-day deadline has subsequently been dropped by the United States as a bureaucratic "error", further teams of US experts are expected in Japan, starting this week.

Japan's space technology is of course still relatively backward and largely developed under US licence. But where Japan has something to offer is in its electronic communications technology, particularly in the use of extremely-high-frequency microwaves to transmit huge quantities of data from satellites to the ground.

Japan's defence agency has, in fact, already completed a study of SDI aimed at assessing the efficiency of both chemical and nuclear-pumped X-ray lasers. Although the study seems to say only that enormous improvements in aiming accuracy would be required to shoot down intercontinental ballistic missiles, that it was carried out at all is an indication of the extent of Japanese interest.

In theory, Japan should have no military forces at all; Article 9 of the constitution (forced on Japan by the United States at the end of the Second World War) says that "land, sea and air forces, as well as other war potential, will never be maintained". In fact considerable "self defence" forces have been in place for years. But until very recently the Japanese government has regarded supplying military technology to foreign countries as going much too far. In 1983, however, considerable pressure by the United States forced Japan to accept a bilateral agreement allowing the transfer of military technology to the United States — again, US interest lay largely in the communication field.

Star wars would be another step up in Japan's military involvement with the United States, but would be seen as a step onto a slippery slope by opposition socialist parties. Government representatives have already had to resort to semantic juggling to make a possible involvement respectable. Military technology transfer is as yet possible only to the United States, but SDI would probably involve other countries. The Foreign Ministry's Treaties Bureau chief Hisashi Owada sidestepped this issue by saying Japan can help the United States with the research, "even if NATO countries take part in it, so long as military technology supplied to the United States remains there".

If SDI research does go ahead, it will bring closer the day when Japan's giant corporations can go into the military export business. But Nakasone may find there is more opposition to the plan from the general public than he has bargained for. Like other world leaders, he has found it easier to agree with Reagan when having a cosy face-to-face chat than to sell Reagan's ideas back home. Nakasone is scheduled to have his next get-together with Reagan on 2 May, just before the Bonn summit, and star wars is high on the agenda.

David Swinbanks

Spain

Law of Science brings change

Barcelona

SPANISH research institutions are likely in the next few months to face a similar upheaval to that experienced in the universities as a result of the Law for University Reform (see *Nature* **312**, 8; 1984).

The Spanish government has now approved the Law of Science (Ley de Fomento y Coordinacion General de la Investigacion Cientifica). The bill has been sent to parliament, where the Socialist Party has an absolute majority in both houses, and a vote is expected before the end of the year. Government approval of this law, after months of discussion between different ministries, may represent an important step in the reform of the organization of research in Spain.

The Law of Science aims to establish mechanisms to define research priorities, to programme the resources for research and to coordinate the work of those in universities and research institutes. The bill also aims to redefine the role of the main public bodies concerned with research, which until now have often had overlapping functions because of the accumulation of 50 years of contradictory legislation.

Under the new law, the National Plans for Research will define research priorities and determine how public funds should be distributed. The draft of a National Plan for Research and Development for the next five years has also been presented as an annex to the law. Subjects to which it would give priority include microelectronics, biotechnology, transportation technology and high-energy physics. Fellowships tenable both in Spain and abroad are intended to double the number of researchers in industry and public organizations within five years.

The Law of Science also proposes a new structure for the main public research bodies, including CSIC (Consejo Superior de Investigaciones Cientificas) and JEN (Junta de Energia Nuclear), to be called the Centre for Energy, Environment and Technological Research. They will be organized so as to promote the mobility of staff between different institutions.

The need for a change in the regulation of Spanish research has been generally acknowledged. Officials in the Ministry of Education and Science believe the new law may help to break down the barriers between people doing the same work in different departments, to promote interaction between public and private research and to continue the trend towards better scientific control and less bureaucracy in the administration of public resources. If these reforms are coupled with increased public and private spending on research, the law will enhance Spain's contribution to science and technology.

Pedro Puigdomenech

Cancer research

France moves ahead

FRANCE is moving ahead of Britain in cancer science, according to a literature review* carried out by Jean-Claude Salomon and a colleague at the Institut de Recherche Scientifique sur le Cancer at Villejuif near Paris.

Salomon based his studies on the 300 or so key papers selected annually for summary in the *Year Book of Cancer*, a regular series of reviews of the world cancer literature produced for the education of US doctors. The yearbooks, edited at the M.D. Anderson Hospital and Tumor Institute in Houston, Texas. "satisfy certain criteria of rigour and objectivity", says Salomon, "though they may perhaps favour American authors". The editorial board of 155 discipline specialists contains representatives from 14 countries, but most members of the board are American. Each year, this board selects the most significant papers from among around 50,000 published each year in 1,200 major journals for summary in the yearbook.

Using this source as a measure of international productivity of cancer science (including clinical papers), Salomon discovered that from 1965 to 1982, the proportion of papers summarized in the yearbooks that were British had declined from 8.3 per cent (the then highest figure outside the United States) to 4.2 per cent, whereas French articles had climbed from 2.3 per cent to 4.6 per cent, putting France in the role of leading nation for cancer research outside the United States.

The founder-editor of the yearbooks (and founder of the M.D. Anderson Tumor Institute), Dr Randolph Lee Clark, believes these figures may well represent real trends. While France had seen fit to invest in 25 "cancer centres" during the period reviewed, the British scene had been almost stagnant, he observed.

Salomon's figures also show a poor result by West Germany and by Israel, each with under one per cent representation in the yearbooks.

In France itself, the clearest signal from Salomon's review is that there has been a strong shift in cancer science from Paris to the regions. Between 1965 and 1976, three-quarters of French articles summarized in the yearbooks came from Parisian institutes. But from 1978 to 1982, Paris could claim little more than half, a result with statistical significance at the one-in-a-thousand level, according to Salomon. In particular, the renowned complex of institutes at Villejuif, including Solomon's own workplace, which had more than 40 per cent of the articles in the first period, had only 12 per cent in the second. This may be a measure of the effectiveness of a big French effort at decentralization 12-15 years ago.

Could there be bias in the selections? Dr Clark claims not, and that he tries to ensure that "there are no national barriers "in the coverage of the yearbook. The sole British representative on the editorial board, Dr Neils Atkin, cytogeneticist at Mount Vernon Hospital, Middlesex, described Salomon's observations as "rather sad" for Britain and added that "I can't think of an explanation that would give us any relief". The editors try to be objective, he said. **Robert Walgate**

Heavy ions

Darmstadt to leapfrog Berkeley

Hannover

THE heavy-ion laboratory at Darmstadt, south of Frankfurt, last week received its reward for its discovery of element 109 three years ago — DM275 million (£65 million) with which to build a bigger and better ion accelerator.

The West German federal minister for research and technology, Dr Heinz Riesenhuber, announced on Thursday that the laboratory would be allowed to go ahead with a plan it had nurtured for at least the past four years. The scheme is to feed ions from the existing linear accelerator UNILAC, at an energy of up to 20 MeV per nucleon, into a synchrotron designed to yield energies 100 times as great. There is also to be a storage ring equipped to bunch and to homogenize the velocity of heavy ions from the synchrotron.

Those working at the laboratory are ecstatic about the prospect. While the maximum energy from the new machine is not very different from that of the similarly constructed BEVALAC at Berkeley in the Unites States, the intensity at Darmstadt will be greater by a factor of 1,000.

The search for other exotic nuclei continues at Darmstadt, even though people talk less confidently now than a few years ago of a possible "island of stability" in the region of atomic number 116 where heavy nuclei would be relatively stable. Indeed, the existing linear accelerator has just finished a two-week run looking for signs of element 110 in the collision of nickel and lead ions. But people now insist that the intended machine will be justified even if no further heavy elements are found.

One field of interest is the beta-decay of heavy nuclei stripped entirely of their orbital electrons. Collisions at 2,000 MeV per nucleon may also simulate the condition of nuclear matter, as in neutron stars, while there is virtually the whole of the atomic structure of heavy ions with many charges to be explored. On the technical side, there are interests in the use of heavy-ion beams for pumping X-ray lasers, and for investigating the properties of dense cold plasmas (which may be crystalline).

The plan is that the extension of the Darmstadt laboratory should be completed in the next five years. The laboratory hopes to increase its staff (now 450 with 50 supernumaries), although not by the whole of the 70 positions asked for. Of the extra funds now made available, 90 per cent will come directly from the Federal Ministry of Research and Technology, while the remainder will be divided (in the ratio 9:1) between the federal government and the *Land* of Hesse. The laboratory's budget is now DM 80 million a year.

John Maddox

Director for Newport News facility

Washington

HERMAN Grunder of Lawrence Berkeley Laboratory in California has agreed to assume on 1 May the directorship of the Continuous Electron Beam Accelerator Facility, the machine that may be used to study "bags of quarks" and that is to be built in Newport News, Virginia, by a consortium of south-eastern universities led by the University of Virginia.

Grunder's decision to accept the position is seen as a major step toward legitimizing the project, which has been plagued with political and technical problems from its start two years ago.

First there was a major political battle with Argonne National Laboratory over who should build it. Although the Department of Energy Nuclear Science Advisory Committee (NSAC), traditionally the last word of the physics community, endorsed the Virginia group's proposal, Argonne broke protocol and appealed directly to the Secretary of Energy, enlisting the aid of the Illinois congressional delegation. In the process, enough questions were raised about the technical expertise of the Virginia group, the technical feasibility of its design, and the accuracy of its cost estimates (which have already grown from the $100 million figure presented to NSAC to more than $200 million in congressional testimony last year) that a sceptical Congress insisted on a go-slow policy. Construction funds requested in the very first year have yet to be approved. The resulting lack of confidence in the physics community that the project would ever in fact begin made recruitment of a director difficult.

Meanwhile, though, the accelerator received a much-needed boost when NSAC, asked by Congress to re-evaluate the project, gave it a firm reendorsement.

Stephen Budiansky

Bhopal aftermath

Legal complications mount

Washington

THE lawsuit filed in New York two weeks ago by the government of India on behalf of victims of last December's disaster at the Bhopal Union Carbide plant has placed on the table a complex series of legal issues that will have to be resolved before even an out-of-court settlement can be reached.

Two of the thorniest questions are whether the US district court will allow the case to proceed in the United States and, if so, whether Union Carbide will be able to countersue the Indian government. To be resolved, too, is the validity of India's claim to be the exclusive representative of the victims and the status of nearly 1,000 lawsuits filed by victims in Indian courts.

In preliminary hearings last week, Judge John Keenan refrained from showing his hand on any of these issues. But, invoking the broad discretionary powers accorded federal judges in the United States, he urged Union Carbide to make an immediate contribution of $5-10 million for emergency relief; Union Carbide the next day agreed to turn over $5 million. Both Keenan and the company made clear that this was not an admission of liability (or even of the US court's jurisdiction).

From the start, the Indian government has said it intended to sue Union Carbide in the United States. Although any compensation awarded by US courts for lost wages, for example, would be based on Indian standards, US courts are much more generous in their compensation for less tangible losses, such as pain and suffering, than are their Indian counterparts.

Awards in US courts are set by juries, usually more sympathetic to victims; Indian cases are heard by judges only. And Indian judges have been very reluctant to award punitive damages, except in cases of clear deliberate wrongs. US courts generally allow punitive damages against defendants who have shown reckless disregard for safety, even when not deliberate.

If Keenan agrees to hear the case, the pressure on Union Carbide to settle out of court will increase measurably. The company has already made one offer of settlement, unofficially put at $200 million, an amount reportedly equal to its insurance coverage. The Indian government has rejected that offer.

If the case is tried in the United States, the company would be facing the real possibility of a judgement of perhaps $1,000 million, approximately one-tenth Union Carbide's entire net worth. The pressures on the company for a settlement are already considerable in any case.

But meanwhile Union Carbide is applying some legal pressures of its own to urge concessions on the other side. The compay's lawyer has made it clear that he will argue that the case should be heard in India as the more appropriate forum. He has also suggested he may move to have the US law firm retained by the Indian government disqualified because it once represented Union Carbide, though on an unrelated matter. And there is also the threat of a countersuit against the Indian government. Normally, governments enjoy "sovereign immunity", and cannot be sued for their actions. But under US law, a foreign country that brings suit in a US court cannot claim sovereign immunity in defence against counterclaims. Union Carbide would probably argue that by allowing squatters to settle near the Bhopal plant in defiance of municipal plans, the government shares responsibility for the injuries.

A wild card in any resolution of the claims is who has the right to represent the victims. The Indian government has enacted a law declaring the government the exclusive representative, while allowing victims to hire their own lawyers who could join the government's action. One faction of the US lawyers who signed up victims — a faction that has been hoping to organize the case into a class action — is challenging the Indian law in Indian courts. It is being joined there by Indian lawyers whose suits filed against Union Carbide in India have been frozen by the law.

Stephen Budiansky

Handicapped infants

Physicians win the day

Washington

THE furore that greeted the Reagan administration's regulations for the treatment of handicapped infants seems finally to have been quelled. Last week, the Department of Health and Human Services (HHS) issued new rules that for the most part defer to the physician's judgement in deciding how to treat such infants and that keep the federal government out of the enforcement business.

The new rules, the result of an arduously crafted congressional compromise last fall, require only that each state's child abuse agency should develop procedures for investigating and "responding" to reports of medical neglect of infants and that they have the legal authority to seek a court order to prevent "withholding of medically indicated treatment". The rules do not apply to cases in which the treating physician believes, in his "reasonable medical judgment", that:

- the infant is in an irreversible coma;
- treatment would merely prolong dying, fail to correct all of the infant's life-threatening conditions, or otherwise be futile; or
- treatment would be virtually futile and would itself under the circumstances be inhumane.

Earlier versions of the rules stirred great resentment among paediatricians and hospitals. Under the original rules, issued in the spring of 1983, hospitals were required to post prominent signs warning that "discriminatory failure to feed and care for handicapped infants in this facility is prohibited by federal law".

The rules also established a "Baby Doe hotline" for receiving reports of medical neglect; HHS set up an investigative team that would be sent out on short notice to examine these reports. The hotline received about 400 calls, most of them from cranks; in the four cases examined no violations were found. But critics complained that the parents of the infants and the hospitals had been put through a needless ordeal. The regulations had been in effect for only a month when they were thrown out by a federal judge acting on a lawsuit brought by the American Academy of Pediatrics and others.

The physicians' organizations also argued that the two well-publicized cases were carefully scrutinized by state authorities, and in both cases local courts refused to intervene. Almost all states include medical neglect in their definition of child abuse; courts have often intervened in cases where parents have refused to allow treatment for their children on religious grounds. The physicians' group thus argues that no federal involvement is necessary.

The new rules indeed go a long way to acknowledging that, and make clear that the federal government is not to establish standards prescribing appropriate treatments. In ordering HHS to issue these rules, Congress in fact seemed chiefly concerned with defusing the issue in such a way that the administration — and the right-to-life groups that the administration had been appealing to in issuing the original rules — could save face. Physicians' organizations remain concerned, however, that even the new rules will put improper pressure upon paediatricians always to choose heroic, aggressive treatment for fear of being accused of withholding treatment.

HHS says it received 116,000 letters commenting upon a draft version of the new rules, published in December. One major change that HHS made from the draft to last week's final version was to remove a set of definitions of terms from the body of the rules into a non-regulatory appendix. Physicians said the definitions of such terms as "life threatening condition" included specific examples and placed the federal government in the position of dictating specific procedures. The six principal Senate sponsors of the compromise bill urged the agency to consider these complaints seriously, noting that there was a danger of undoing the careful balancing that went into the bill.

US universities

All change at St Louis

St Louis, Missouri

THE Washington University, part of this city's pride (after the arch across the Mississippi and its baseball team, the Cardinals), is part way through an administrative revolution that keeps many of the faculty awake at nights. Two years ago, the trustees decreed that the School of Arts and Sciences should follow the professional schools into financial and administrative autonomy. One result could be that academic departments less able to fend for themselves financially — philosophy but even physics — might go out of business.

The School of Arts and Sciences has had autonomy thrust upon it. Two years ago, it was the only school of the university not paddling its own canoe. The argument for change starts from the observation that other schools that have been independent for some time (medicine conspicuously) have prospered, partly from the ease of making deals with outside backers and partly by commanding the loyalty of their alumni. But then, as the administrators are fond of saying, is this not what the Harvards of this world do?

Under the arrangement, called "being put on reserve" in reference to the share of the whole endowment that autonomy commands, a school is the fiefdom of its dean. Policy on admissions, curriculum and even salary levels is determined separately. Now, in the School of Arts and Sciences, tuition fees (in excess of $8,000 a year for undergraduates) go into a pool with other income, but the school pays a levy to support central activities.

Worries among the faculty take several forms. The philosophy and classics departments (large and small respectively) may not be financially viable, but can a university claim the name without offering courses in such fields? But even physicists fear that the engineering school, which now pays a fee to arts and sciences for service physics teaching, may decide to teach its own physics as an economy. (The chancellor, Dr John Danworth, says the service fee, fixed by the trustees, could not be changed without their consent.) Then there is the general worry that autonomy will turn all academics into fund-raisers, or that only successful fund-raiders will prosper.

The chancellor is anxious that autonomy should work, but is for the time being open-minded about the change. If it does not bring the benefits intended, the trustees would think again. And a successor might wish to see the omelette unscrambled. But in Danworth's view, only autonomy can make a faculty responsible for its academic future. He cites his own earlier success, as head of the medical division, in turning a bankrupt dental school into a successful enterprise with the help of a tapering subvention from the centre ($600,000 over three years) coupled with the threat that failure would spell closure.

In any case, Danworth says, it is no longer possible for the head of a private university, forever occupied with fund-raising and negotiations with government agencies, to be so involved with academic life as to provide single-handed academic leadership. This leads him, after careful thought, to an unyieldng position on the issue of the weaker departments; if the faculty of arts and sciences should think of closing one of them, the whole value of independence would be lost if he or the trustees should intervene to halt the closure. But what a chancellor can do is to fire a dean who has failed to carry the faculty with his decisions. Danworth is said to read faculty meeting minutes like a hawk.

Ultimately, the success of the experiment will hang on whether arts and science can raise the funds needed to stay alive, and on whether the faculty is sufficiently committed to the ideal of a liberal education for the well-to-do to indulge their less commercially viable colleagues.

That money is so dominating surprises nobody at St Louis, although most academics are more concerned with the competition for high-quality students, which they say is a prerequisite for commercial success. They point to rising scores in the national college boards examinations and a widening catchment area (with only 20 per cent of undergraduates from the locality). Physics has now followed engineering in offering a handful of undergraduate scholarships, saying that even students who compete unsuccessfully for them leave their applications in. The faculty also claims that other universities are prevented by the egalitarian climate from following this elitist course.

So far, the university has been lucky in its donors. The chemical company Monsanto, only one of the reasons why East St Louis (across the river in Illinois) is such a slum, made a 5-year grant of $27 million to the medical school two years ago, from which non-medical biologists also profit. McDonnell Douglas, the aircraft manufacturer, has been generous over several years, partly because of the interest of the late founder of the company (known generally as "Mr Mac") in space research (whence the flexibly endowed McDonnell Center for Space Research) and in parapsychology (engendering less pride). By contrast, General Dynamics, also based in St Louis and now in trouble for misdemeanours such as lodging a senior manager's dog in a commercial kennel at the Pentagon's expense, is almost conspicuous for the modesty of its support.

As a research university, Washington dates its rise to the post-war chancellorship of A.H. Compton, who arrived at St Louis in 1945 with a group from Los Alamos. More recently, the medical school has made the running.

For a big-city urban university, Washington is suprisingly well-provided. It is compact (mostly on one campus, with the medical school two miles downtown) and hemmed in by amenities such as Forest Park, the site of the world's fair in 1904 which persuaded the rest of the United States that St Louis is not some outlying suburb of Chicago (more than 300 miles away). The setting is also a physical constraint on growth, but nobody wants that any more. The snag is that even successful departments may be smaller than a critical intellectual mass which is why, whatever the consequences of autonomy for arts and sciences, a measure of concentration may be prudent.

John Maddox

European geoscience union thrives

THE European Union of Geosciences (EUG), at its third meeting in Strasbourg on 1-4 April, appears to have established itself. Since EUG's foundation five years ago under C.J. Allègre of the University of Paris, attendance at the biennial meetings has increased from 600 in 1981 to more than 1,500 this year. The annual spring and fall meetings of the American Geophysical Union attract between 2,000 and 2,500 participants.

The need for such a forum in Europe was one of the stimuli for the creation of EUG, says the new president, Professor E.R.Oxburgh (University of Cambridge). There is a particular need, he says, for European earth science research students to meet and to present their work to more established people. To this end, costs are kept as low as possible. This year, more than 200 travel grants, valued at £10,000, were awarded for the meeting. In his presidential address, H.Wänke (Max Planck Institute, Mainz) said that he knew of no comparable organization that spends so much of its income in this way.

EUG works on the principle that membership is strictly individual. Other than a part-time secretary provided by the European Science Foundation, the union has no permanent administration. Allègre says that EUG is essentially anti-bureaucratic.

Meetings are organized in turn by members from one country. The 1985 meeting was arranged primarily by the University of Cambridge, and the next(in 1987) will be organized by Eidgenossische Technische Hochschule, Zurich. After that, Italy will probably take over. All the meetings will take place in Strasbourg. Although some officers feel that this rotation of responsibility is a strength, others fear that growth may make a more permanent administration inevitable.

Peter Gambles

Hannover trade fair

Something for everybody

Hannover

THE world's largest and glossiest trade fair has become a supreme test of endurance. While the organizers boast of having crammed 60,000 cars into the car parks, yawning salesmen excuse themselves by saying they have just spent three hours in traffic.

Inevitably, innovation tends in these circumstances to be deeply buried in the products that people want to sell, preferably on the spot. But, after a week's spring sunshine, solar cells made of amorphous silicon abound, making enough electricity to circulate water in a toy swimming-pool or to light mock traffic lights. People like Interatom, a subsidiary of the nuclear energy constructor Kraft-Werke Union, say the opportunities for special uses are now rapidly increasing, the uneconomic character of solar cells notwithstanding.

Hannover's research ghetto, a building with the subtlety and floor-area of an aircraft hangar, is lavishly sprinkled with displays by West German universities of all kinds (of which there are three), most of them seeking industrial backing for research begun with public funds in academic laboratories. The phenomenon is partly instinctive and partly federal and local (*Land*) government policy. Industrial exploitation has become the watchword. (Some say it always has been.)

Academic stallholders hope to benefit in several ways. Professor Bert Kuppers from the Fachhochschule at Aachen (a technical college not to be confused with the university at Aachen, called the Technische Hochschule) has a model of a generator capable of taking the variable-speed output from a windmill and producing constant-voltage 50 Hz current; if he is able to find a backer before the week is out, he will be in business.

Others look for industrial support to help win government grants. Professor Gerhard Muller from the Gesamthochschule at Essen, for example has developed a technique for coating objects made of materials such as plastic with metals of almost any kind. The principle is to use materials evaporated from an anode both as the working gas for a discharge and the coating substance. The development has cost the university less than DM 50,000 so far, but if the fair can recruit enough industrial testimonials, the chance of winning a big government grant will be bright.

On the biological front, pollution control and tree death are the prominent issues. The University of Oldenburgh has constructed a prototype of a self-contained system for processing sludge from sewage works which yields an oil-substitute rich in aromatic hydrocarbons and runs on energy by burning waste gases, so that the return of waste to the environment is kept to a minimum. (The one per cent of residue contains tightly-bound metals, which may yet be reclaimed.) This is a project supported so far by the government which now needs industrial support.

The Karlsruhe nuclear research centre is on a similar tack with a pilot plant for burning rubbish in a self-contained environment. Heat makes electricity, and waste acid gases in solution can be used in reclaiming heavy metals from the solid waste.

Tree death is West Germany's anxiety just now, with the lumber industry an important part of the agricultural economy. The University of Freiburg and the Karlsruhe centre (the Kernforschungszentrum) have both developed techniques for identifying damaged trees from infrared photographs, and the use of these methods has already helped to suggest the sources of damaging pollution on the Western edge of the Black Forest. And people are growing trees in controlled test chambers, as the Gesellschaft fur Strahlen und Umweltforschung in Munich is eager to proclaim, so that the physiological and biochemical effects of the various pollutants can be investigated individually.

This is the plentiful small change of the research on display, which is most of all impressive for the diversity and ingenuity of the academics. At the other end of the scale, the major research establishments under the umbrella of the Arbeitgemeinschaft der Grossforschungseinrichtungen (big science spelled out) are also eager that passers-by shall recognize the useful things that they can do.

Radio-frequency resonators built as means of feeding power into particle accelerators (as at DESY, the Hamburg accelerator laboratory) are offered as being capable of other jobs. The Darmstadt laboratory (which accelerates heavy ions) also offers its beams as a way of punching micro-holes in pieces of material, if a little unconvincingly.

This group of a dozen national laboratories is exceedingly diverse and a little uncertain about its future. In the last year of the five-year government demand that spending should be reduced by 1.5 per cent a year, the organization has been cheered by the federal government's decision (see page 662) that Darmstadt should expand. But there is now some dismay that the umbrella organization should have been told, a few weeks ago, that it will have to make reductions of spending by differentiating among the twelve establishments, which range from the cancer research centre at Heidelberg to the national aerospace organization which is scattered over West Germany. People fear this new policy as a recipe for internecine strife in what was previously a self-contented organization.

The federal minister for research and technlogy, Dr Heinz Riesenhuber, gave away nothing on the degree of economy expected when he popped in by helicopter last week. (Helicopters land in the car park, whence ministers are ferried between cars full of machine-gun-toting police.) The minister shook hands or patted heads as appropriate, and held a public long-distance conversation of conspicuous banality with the West German research station in the Antarctic before being whisked away.

The Antarctic programme is nevertheless big — the annual budget runs at DM 65 million a year. One of its more intriguing sets of observations is that of the tides on the ice shelf at the entrance to the Weddell Sea, from which it is hoped eventually to disentangle simple ocean tides and those affecting the floating ice.

Industrial research is prominent, although electronics research is curiously inconspicuous. (Nobody has a stand devoted to the making of silicon chips.) The West German love affair with the motor car is illustrated by the large crowds around the Mercedes-Benz and Volkswagen stands. Preussac, the minerals extraction company, has a vivid exhibition of ores dragged up from the sea-bed, but is not especially hopeful that it will make money from its interest.

For the rest, the fair's technology is a curious contrast between the machines with moving parts and those which seem to have none. (The halls housing the mechanical machines are, by comparison, as quiet as cathedrals.) This, no doubt, is one reason why the organizers think they can safely split the fair next year. Most machinery-makers show something very old — Thyssen, for example, has a coal-burning locomotive outside its stand.

The computer people, by contrast, are all bustle. Apple, the US computer maker, has the best crowd-puller — it has simply provided 60 machines with which people can play if they fight their way to the head of the queue. Toshiba's illusionist is also a draw, but is there merely to suggest that his sponsors' photocopiers are magical. Given the time and energy, a person could decide which system will best meet his needs, although the computer-watchers are chiefly interested in computer-aided design and the like, which goes to show that this fair has become an essential part of West Germany's system of technical education.

Not everything is on this high plane. The lighting-hangar does give some manufacturers of specialized lighting systems a chance to show off, but it is mostly a display of lampshades of the kind that one might find (but would prefer not to find) in one's living-room. And an Australian company is selling (like "hot cakes") audio tapes of the sound of the ocean waves in which, it is said, there are hidden messages that will subliminally allow one to become better-adjusted in one of a dozen specific ways. How to live with traffic jams might be a good title for next year. □

Embryo research (contd)

SIR — The status of the early human embryo has been background music for much dancing on the head of a pin. The latest example is provided by C.B. Goodhart (*Nature* 14 March, p.126). He finds justification for "use of IVF embryos for experimental work expected to result in death" in the following argument. The fertilized egg *ex utero* is like an unfertilized egg in that voth require external action to realize their potential to become an adult, the fertilized egg requiring activation by a sperm (or a substitute). But, the argument continues, fertilization does not really change "right to life" status because that right relates to being human and alive — which is characteristic of both gametes and zygotes. *Ergo*, since zygotes and early embryos *in vitro* will, like unfertilized eggs *in vitro*, die without external help, both are ethically available for experimentation unto death.

After vertigo subsides, one asks why the discovery does not apply to zygotes or early embryos in normal reproduction. Easy — "the embryo *in utero* has of itself (*sic*) the full potential to complete its development without any further intervention from outside". Possible parallel — the bank robber, once inside the bank and having cowed the cashier, has earned his ill-gotten gain because he can (barring police interference) carry it outside without further external aid.

But now, in truth, the embryos (blastocysts) *in utero* and *ex utero* have exactly the same potential, as demonstrated by normal development of *ex utero* blastocysts when transferred to a physiologically prepared uterus. Moreover, the state of both is very different from that of an unfertilized egg by virtue of the *genetic* individuality conferred by gamete fusion.

If there are good reasons why IVF embryos should be available for clinical investigation (and I believe there are), the justification is better provided through contemporary ethics and science, rather than from a return to scholasticism.

CLIFFORD GROBSTEIN
Program in Science, Technology and Public Affairs,
University of California, San Diego,
La Jolla, California 92093, USA

SIR — C.B. Goodhart's argument (*Nature* 14 March, p. 126) that embryos fertilized *ex utero* lack independent viability and therefore are not potential human beings like their brothers and sisters in the womb after natural conception, is at first glance attractive, in that it might allow one for instance to be anti-abortion yet pro-experimentation on very early embryos; but it involves the debatable assumption that what comes naturally is outside our control in the sense that we can interfere with it only negatively, whereas for an embryo fertilized *in vitro*, positive intervention is required for its survival. Is this a legally or morally valid distinction, especially for physicians and surgeons dedicated to interference with nature and rightly regarded as culpable if they do not do so when asked in the supposed interests of a patient, and might not feminists enquire whether their sex must regard themselves as the passive and vegetative receptacles of an embryo implanted in their womb by any male (or even by the Holy Ghost) who succeeds in depositing in them the necessary seed? Surely it is time we left the suspect word "natural" to advertisers of semisynthetic foodstuffs and took it upon ourselves to live up to the very worrying responsibility that we have for ordering our own destinies; or do we no longer assume that what man does is no longer part of nature since he is no longer mainly concerned with adaptation to his environment, but can adapt it to himself?

Value-laden science

SIR — M. Hammerton's letter (*Nature* 31 January, p.343) demonstrates unwittingly that it is more difficult to identify value-free science than the unwary might realize.

The statement which Hammerton believes to be value free, "The lethal dose of cyanide is x gm/kilo body weight", contains implicit value judgements in the definition of "lethal dose" and how this relates to the real world, for example a coroner's inquiry. Is the lethal dose for a particular human individual determined better on the basis of extrapolation of LD_{50}s from animal experiments, or from a smaller sample of mortality data collected from other humans? Furthermore, independent of the definition of "lethal dose", if the forensic evidence indicates that the victim has a body burden of $0.2x$ gm/kilo, was cyanide the cause of death? Whatever the body burden of cyanide, what other factors ignored by the forensic evidence (such as the psychological state of the victim) could be relevant to the death? To answer such questions, value judgements are unavoidable.

Ironically, the statement which Hammerton believes is value-laden, "I am going to poison my spouse", can be interpreted as a statement of pure intention or as a prediction of one's own future behaviour. With these interpretations, although the statement is unpleasant, it contains no ethical, social, political or other evaluative judgements, and so can be considered to be value free. To make it clearly value-laden, one could re-interpret it as "Rather than (say) shoot my spouse, I shall use poison", or one could modify it to "It is good/socially desirable/profitable to poison my spouse".

Although the matter is controversial amongst philosophers of science, people might wish to hold a "pure" mathematical statement, such as $2+2=4$, is value free in its content. However, even then the context could in some cases make it value laden: for instance, if it represented a reductionist approach to a scientific problem which some researchers believe can only be treated adequately by a holistic approach.

Sizewell inquiry

SIR — Your leading article (28 February, p.723) on the prospects for UK energy policy following the ending of the Sizewell inquiry and the coal industry strike raises a number of important questions. Unfortunately, it would demand too much space adequately to respond to all of them. I wish therefore simply to point out one factual error rather than to take issue on matters of interpretation.

You state that part of the explanation for the extreme length of the Sizewell inquiry (340 sitting days taking just over 2 years) was the inspector's decision at the outset to allow documentary evidence to be accepted only if it was read aloud, but this is not true. The inspector did require the proponent party, that is, Central Electricity Generating Board witnesses, to read their proofs of evidence in full so that their case would be fully set out in public. This is not so with the opposition. Groups or individuals who appeared in person were requested to summarize their evidence, sometimes to the considerable disadvantage of the objectors, as additional personal time had to be devoted to preparing such a summary in a cogent but no less coherent form.

In addition there were 112 entirely written submissions, of which the inspectors stated on the final inquiry day (p.79 in transcript): "I would like to add that I will take into account *all* these written representation in preparing my report."

I fear that because of your editorial stance that the structure and scope of the proceedings were inappropriate to the issues that ought in your judgement to have been under review, you may have overlooked some very important aspects of changes in energy policy that undoubtedly have emerged from the inquiry itself, such as nuclear waste management. No doubt these issues will persist in new, rather less exotic forums.

All business travellers should have reservations about where they sit.

For action

Please book my seat and arrange for.

Window seat ☐

Aisle seat ☐

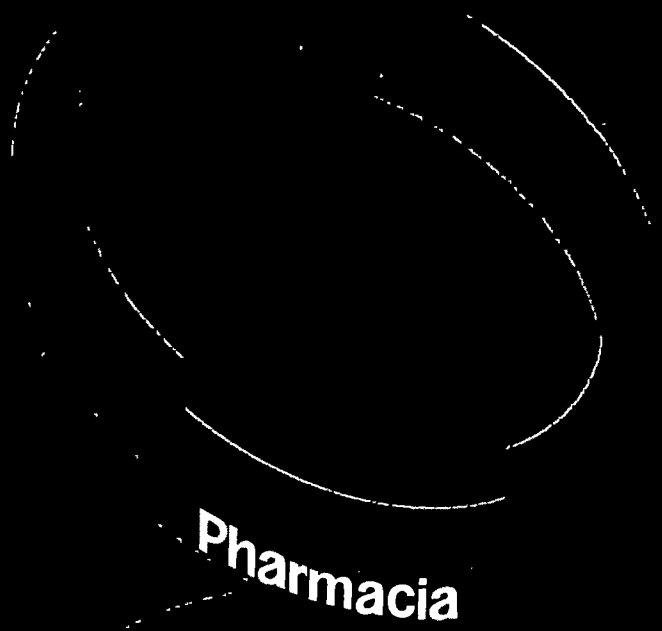
Smoking compartment ☐

Non-smoking compartment ☐

Swissair First and Business Class passengers can now select their seats when they make their reservations, even on the shortest flights The request form above will help you to make sure whoever books your seat also arranges your seat reservation

Up to two weeks before departure we will accept your request for a seat by the window or on the aisle, in the smoking or non-smoking section

When you make a reservation within two weeks of departure we will confirm to you a specific seat number (just as on the long-haul routes) We also assign seat numbers to reservations made more than two weeks in advance



Our Business Class now has separate check-in desks at 59 airports New Business Class lounges are being introduced and on B-747 and DC-10 long-haul flights we now offer a choice of three menus

With the care and attention that Swissair shows to its passengers it's little wonder that readers of Business Traveller magazine have voted us «best airline worldwide» three times since 1980 Most recently in 1984 With no reservations!

Pharmacia

Pharmacia

Seen in all the best scientific circles

Pharmacia's new Molecular Biology Division has been formed by linking the established strengths of Pharmacia P-L Biochemicals with the separations expertise of Pharmacia Fine Chemicals, creating a group with an unequalled technology base.

This group is dedicated to providing molecular biologists with the tools and advice they need in their research.

Whether you are constructing your own plasmids, sequencing, or working with cDNA, we have the products and the fast delivery that you need.

Everything from nucleotides to separation products and enzymes to expression vectors, are available from one dependable supplier.

Look at our new catalogue and you will see just how much we have to offer.

Write or call us today for your free copy.

You'll be in good company.

Pharmacia... your partner in molecular biology.

New ways with aggregation

An improved calculation with the classical equations of aggregation suggests new tasks for those who carry out computer simulations of these problems.

THE fashion for the study of aggregation in all its forms (from the formation of smoke particles to the polymerization of chemicals) is readily explicable. Quite apart from the several practical applications in which a better understanding would be valuable, computer simulations of aggregation processes have opened up an intriguing line of enquiry, confirming among other things that many aggregating particles do indeed have fractal, or non-integral, dimension.

General interest in aggregation is not, of course, new, but goes back at least to Smoluchowski's work in the 1920s. But how to make a bridge between the recent numerical work and the now-classical but phenomenological equations for which Smoluchowski is best known? Two people from the University of Utrecht, P.G.J. van Dongen and M.H. Ernst, have now made a brave attempt (*Phys. Rev. Lett.* **54**, 1396; 1985) which, among other things, has the virtue of suggesting where the computer people should next look.

The two approaches are as different as they could be. The computer simulations are typified by the model of T.A. Witten, which has been much elaborated since it first appeared in 1981. Particles are allowed to diffuse from the edges of some piece of lattice (square or 5 cubic, say), with instructions that they should stick to an aggregate grown from a single particle at the centre if they should happen to reach an immediately neighbouring position. Physically, the circumstances may be likened to those in which crystal growth is limited by the speed with which solute molecules can diffuse through a solution. Aggregates formed in this way do indeed have fractal dimensions. Recent elaborations of this simple model have allowed particles to shift their position after reaching the growth surface of an aggregate, or restrict occupancy of relatively inaccessible sites.

The Smoluchowski argument is more formal, and based on an enumeration of the ways in which aggregates of different sizes can stick together to form still larger aggregates. (The opposite process, disintegration, is supposed not to happen.) Aggregates containing N elementary particles will be formed (to a first approximation) only from pairs of smaller aggregates whose combined size is N. The rate at which this happens will be proportional to the number (or concentration) of each possible pair of constituent sub-aggregates, that is to the product $c_j c_k$ where j and k add up to N. The snag is that the constant of proportionality will depend on the size of each member of the pair of sub-aggregates, so that the rate of formation of particles of size N is something like $K(j,k)c_j c_k$ summed over all possible pairs of constituent sub-aggregates. (A factor of two enters if the sum is written as a sum over both indices j and k.)

The rate at which aggregates of size N disappear is similarly calculated, but now aggregation with a particle of any size will remove an aggregate from the N-sized cohort. The result of adding these two rates together algebraically is a simple-looking set of equations expressing the rate of change of the quantities c_j which are nevertheless intractable (because they involve products of the variables, and are thus non-linear). But this, of course, is irrelevant because nothing is known about the coefficients $K(j,k)$. The hope that the computer simulations might throw some light on the nature of this function is one of the reasons why the subject has recently been fashionable.

Experiment, in the nature of things, can be of only limited help. Light-scattering from an aerosol or a colloid can, for example, provide information about the mean size of aggregating particles and some information about the size distribution. But the chance of defining the infinite set of coefficients $K(j,k)$ by the results of even the most refined experiment is plainly small. So the trick is to try to pin down the coefficients K, considered as a function of two particle sizes, from what scraps of information there may be. And a few generalizations are possible. In aggregating systems, it appears, the mean size does increase steadily with time. Experiments have also shown that in many kinds of aggregating systems, the evolving size-distribution is independent of the initial distribution when a sufficiently long time has passed.

Von Dongen and Ernst set out to generalize an earlier discussion of the problem (in 1966) by S.K. Friedlander. They restrict themselves to functions K which assume the form $j^p k^q$ when the aggregates are large, which is one sign of how much more needs to be done in this field. There are reasons for supposing that the sum of the two constants p and q cannot exceed 2.

Some of the results are nevertheless simple and striking. The formation of a gel from, say, a coagulating colloid requires that the sum of p and q should be greater than unity. Indeed, it turns out that this condition is also sufficient in the sense that if the criterion is satisfied, the system will inevitably gel. And there is much that can be said about the size distribution of particles in a gelling system, both before and after they have set.

The chief interest of the new calculations will however turn on what they have to say about the scaling behaviour of the size-distribution function in all kinds of aggregating systems. Experiments as well as computer simulations suggest that the size distribution of particles in an aggregating system has a degree of uniformity in the sense that the variables c_j (which change with time) can be related to the average aggregation size (say s) by an expression of the form $s^{-r} f(j/s)$ where r is a constant and f some function of a single variable. Von Dongen and Ernst are able to calculate more about the characteristics of such a function, and of its implications, than has previously been possible.

That there should be a simplication of this kind is really remarkable. What it implies is that, with the passage of time, an aggregating system will evolve in such a way that the size-distribution of the particles is similarly related to the mean particle size. Part of what van Dongen and Ernst succeed in doing is to calculate the properties of the unchanging distribution function, in practice by calculating its moments (the mean, variance and so on).

While the results obtained in this way are not inconsistent with what has been learned from computer simulation, there is clearly a great deal to be learned about the relationship between the simulations and the mathematical form of the coagulation function. One would have thought that there is now plenty of promise in attempts to simulate the aggregation process for a few of the special circumstances in which van Dongen and Ernst have shown the equations to be reasonably tractable.

A particularly valuable goal would be the definition of the exact form of the coagulation function when most aggregates are still small. The obvious difficulty is that the numerical programs so far used in these simulations are devoid of much in the way of the physics of what happens when substantial aggregates stick together. To what extent does rearrangement then become possible, for example? That is also a challenge for experimenters. May it be one of the unplanned benefits of the interest in nuclear winter?

John Maddox

Sex chromosomes and evolution

Haldane's Rule OK

from J.S. Jones and Nick Barton

THERE are few rules in biology, and most of those which have been proposed — Cope's Law of the Unspecialized, Haeckel's Biogenetic Law and many others — have sunk into obscurity or have been so confused by exceptions as to lose much of their force. One survivor of more than sixty years is Haldane's Rule: "When in the F_1 progeny of two animal races one sex is absent, rare or sterile, that sex is the heterozygous (heterogametic) sex"[1]. From the paper of J.A. Coyne on page 736 of this issue the genetic basis of this rule can now be seen to reflect some fundamental processes in developmental biology, models of sex determination and speciation[2].

Haldane's rule applies not only in the familiar cases in which it is the males which are heterogametic — for example, the sterile XY male donkeys which result from a cross between horse and an ass — but also in those animals (such as birds, butterflies and snakes) in which the female is the heterogametic sex. Hence males are not innately more sensitive to the effects of interspecific hybridization than are females. Haldane himself (and many of his successor's) felt that the sterility of heterogametic hybrids results from an imbalance between sex chromosomes and autosomes: XX hybrids have two complete haploid sets while XY hybrids lack the full complement of chromosomes from one parental species that is necessary for fertility. Coyne, however, has now shown that, in *Drosophila* at least, this is not true, and that a different mechanism is involved.

Drosophila simulans can hybridize with *D. mauritiana* and *D. sechellia*. Making use of an attached-X stock of *D. simulans*, Coyne generates hybrid females in which both X chromosomes come from *D. simulans*, but one set of autosomes comes from each of the parental species. Such flies have the same degree of discordance between X chromosomes and autosomes as do XY hybrid males, and might be expected to be sterile. Instead, they are quite fertile. X-autosome interactions cannot explain the sterility of heterogametic hybrids: Coyne suggests that it must arise from genetic interactions between the X and Y chromosomes of the parental species.

He confirms this suggestion by producing hybrid flies which (as far as is feasible given the genetic limitations of the stocks available) differ only in their Y chromosomes. Substitution of a *D. mauritiana* Y chromosome into flies which have a *D. simulans* X chromosome leads to a 96 per cent drop in the production of motile sperm, indicating that interactions between X and Y are indeed responsible for their hybrid sterility. Similar interactions might also be responsible for the failure of reproduction in species in which females are the heterogametic sex, as inter-racial crosses of the moth *Lymantria dispar*, in which inappropriate X and Y chromosomes are combined, fail to produce females[3]. However, such interactions between sex chromosomes cannot explain all cases of hybrid sterility. Male sterility occurs in interspecific crosses between some grasshoppers which have an XO sex-determining mechanism (and hence lack a Y chromosome)[4].

It has long been thought that the sex chromosomes diverged from a pair of homologues differing only at a locus determining sex. Meiotic pairing between X and Y in man is quite extensive[5], suggesting that there is homology between the two. A 36-kilobase stretch of single-copy DNA which has been translocated to the human Y chromosome during recent hominid evolution has been shown to diverge by less than one per cent from an equivalent sequence on the X chromosome[6,7] and a 30,000 M_r protein is coded for by a gene on the tip of the human X chromosome which is also present on the Y chromosome[8].

Male sex determination in mammals demands the cooperation of both sex chromosomes[9]. The Y is necessary for testis and sperm formation: human XO individuals are phenotypically female, and in some marsupials that are mosaics for XO and XY cells, spermatogonia are always XY. There is a testis-determining locus on the mouse Y chromosome, mutants of which can lead to male sterility[10]. The X chromosome is also implicated in disorders of male sex determination. In the primary spermatocyte of normal males, the single X chromosome is inactivated. Any retention of its function interferes with fertility: XXY humans are sterile (perhaps because of the presence of an active X in spermatocytes), and translocation of part of the X to an autosome can also lead to male sterility. The Y chromosome may be involved in the repression of the X which is necessary for successful spermatogenesis[11]; this may be why XX human males and 'sex-reversed' male XX mice (both of which have undergone a translocation of part of their Y chromosome to the X) show early degeneration of germ cells[12,13]. Sterility of this kind may result from failure of the Y-linked repressor locus in its new chromosomal milieu; male mice in which the sex-reversed allele is on the Y chromosome are quite fertile.

Direct genetic evidence for the existence in *Drosophila* of Y-linked genes that suppress related loci on the X has recently emerged. The *D. melanogaster* Y carries several genes responsible for male fertility, most of which encode components of sperm[14]. Deficiencies of any of these lead to a series of errors in spermatogenesis. One such mutant is known as *stellate*. Flies bearing this allele suffer from a derangement of meiosis and the production of star-shaped crystals in the primary spermatocyte[15]. A cloned segment of DNA which hybridizes with the *stellate* locus has now been found to contain a 1,250 base-pair segment repeated at least eight times in tandem, which is present on both the X and Y chromosomes[16]. In XO individuals (which in *Drosophila*, unlike mammals, are male) the X-linked copies of this region produce up to 70 times more RNA than is produced by the *stellate* locus in normal XY males, providing direct evidence that genes on the Y are repressing others with a related function on the X, and further support for the view that male fertility involves interaction between these chromosomes.

The distribution of the *stellate* sequence shows considerable differences among various members of the *D. simulans* group. Hence the sterility of heterogametic hybrids — Haldane's rule — may arise from a failure of X-chromosome repression by a foreign Y. The same seems to be true in mice[17]. When a Y chromosome from *Mus domesticus* is transferred into a laboratory strain of *Mus musculus*, XY individuals develop as infertile females or as hermaphrodites, probably because *M. domesticus* Y chromsomes bear a testis-determining locus which cannot interact with the appropriate X-linked locus in *M. musculus*. Although an autosomal sex-determining locus may also be necessary for male fertility in these hybrid mice[18] there is a parallel with hybrid sterility in *Drosophila*.

This new evidence for the importance of the sex chromosomes in hybrid sterility raises some general questions. Why, in most groups, is the germ line more sensitive to hybridization than is the soma; and why should genes that lead to reproductive isolation so often be sex-linked? One interesting possibility might involve 'selfish' DNA, propagated through the germ line despite its deleterious effects[19]. Co-evolution between such DNA and genes that are able to suppress its replication will therefore be most intense in the germ line, which might therefore be unduly sensitive to the mobilization of selfish DNA on hybridization. Examples of selfish genes include B chromosomes in Orthoptera and, in *Drosophila*, segregation distortion, cytoplasmic sterility and the mobile genetic elements that cause hybrid dysgenesis[20-23]. These genes have their greatest effect in the germ line, and their replication may be suppressed by modifiers elsewhere in the genome. It may be more than coincidence that the *stellate* locus involves a tandem repeat, whose structure is similar to other repeated elements in the genome, and whose taxonomic distribution is similar to some of the mobile elements responsible for hybrid dysgenesis[24].

As well as the genes for hybrid sterility, a disproportionate number of interspecific

differences seem to be sex linked. Not enough information is available on protein or DNA structure to test whether X-linked structural loci show undue divergence among species[25]. However, many genes for mating preferences are on the X chromosome in *Drosophila* and some butterflies[26,27], and sex chromosome rearrangements are frequently found when related Orthoptera are compared[28]. In the Australian grasshopper *Caledia captiva*, the hybrid zone for the sex chromosomes is much narrower than are those for the autosomes; there are stronger linkage disequilibria for sex-linked characters; and there is much less introgression between races for characters borne on the X chromosome than for those on the autosomes[29]. All this, together with the marked differences between male and female viability which emerge in reciprocal backcrosses, shows that the sex chromosomes are subject to much stronger selection pressures in hybrids than are the others.

This close involvement of sex chromosomes with species differentiation might arise in several ways. If speciation involves population bottlenecks (as is often suggested), then genetic drift will act more strongly on the relatively small population of X chromosomes than on the autosomes. In addition, sex-linked differences are subject to less selection against heterozygotes and recombinants in hybrids than are those carried on autosomes. Lande's estimates[30] of the rates of chromosomal evolution in insects and mammals imply an excess of sex-linked differences which is sufficient to account for those observed in nature. In addition, genes under sexual selection (which may be a potent force in the evolution of reproductive isolation[31]) may evolve more rapidly when sex linked, and the 'hitch-hiking' effect of closely linked loci may also be more important for genes on the X chromosome[25,32].

Predictions of the mechanisms of DNA replication, of molecular mimicry by parasites and of kin selection and selfish genes can all be recognized in Haldane's early writings[33]. His discovery of the regularities which underly the sterility of hybrids seems set to become equally important in modern biology. □

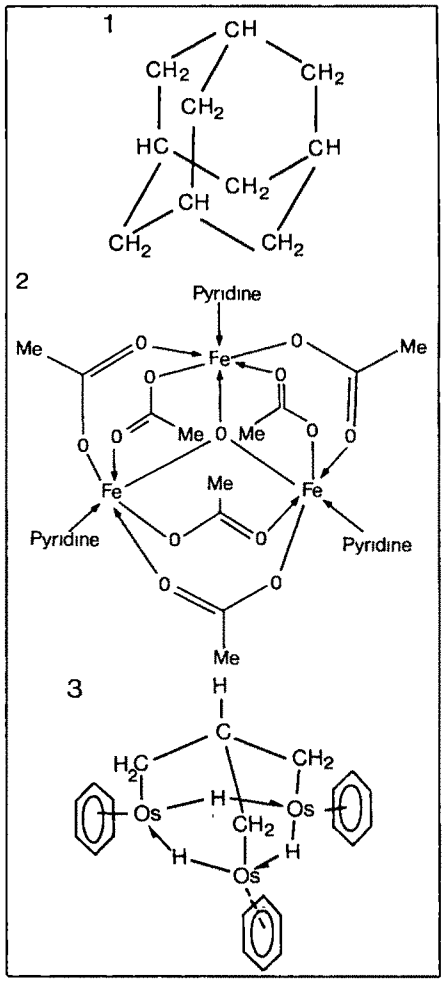
Chemistry

Activating the C–H bond



from J.M. Thomas

THE paper by Ito and Lunsford on page 721 of this issue[1] should interest chemists of all complexions, and others too, who are aroused by the challenge of effecting controlled activation of C-H bonds, especially in molecules such as methane (CH_4) the simplest of saturated hydrocarbons and the main constituent of natural gas.

It is not difficult to sever all four C-H bonds simultaneously: the ease with which this complete and relatively uncontrolled oxidation is accomplished is what makes natural gas a fuel. Ways of partially oxidizing CH_4 to produce synthetic gas ('syngas') are also well known: this is the first step in present-day industrial methods of catalytically synthesizing methanol, acetic acid and many other products, including vinyl and acetate polymers[2]. Much scope exists for exploiting syngas in new ways. The integrated process, now operated on a pilot scale by Haldor Topsøe in Copenhagen, for synthesizing gasoline using a zeolite catalyst is one example; the laboratory synthesis by Jones *et al.*[3] of acetylene using a de-intercalated graphite catalyst is another. But how far have we progressed in rivalling the comparative ease with which nature performs subtle, milder oxidation of relatively stable molecules?

For a start, organic[4] and organometallic[5-8] chemists have recently been devising ways of emulating the performance of enzymatic systems, such as the non-haem iron protein ω-hydroxylase or the iron-porphyrin-based cytochrome P-450 which selectively hydroxylate unactivated C-H bonds. And theoretical chemists have been trying to identify the factors that influence the transfer of electrons between a transition metal atom or surface and the bonding and antibonding orbitals of the C-H bond in simple paraffins[9].

In addition, at least two distinct lines of experimental attack have been used to activate C-H bonds in saturated hydrocarbons by chemical means. Organic chemists have tended to focus on molecules rich in tertiary and secondary C-H bonds, such as adamantane (1). These bonds are a little easier to activate than the primary bonds of methane. Encouraging results have been achieved using a tri-iron cluster compound (2) which, in the presence of other reagents, catalyses the conversion of adamantane to corresponding alcohols and adamantone at room temperature[4]. Like a variety of metal surfaces, bare metal atoms, under the right conditions, are undoubtedly capable of activating the C-H bond. For example, compound (3) is prepared by the co-condensation of osmium atoms and a

1:1 mixture of benzene and 2-methyl propane[8]. Its precise mode of formation is unknown, but presumably involves intermediate steps in which unsaturated metal centres of discrete osmium intermediates activate the C-H bonds of 2-methyl propane. The very existence of (3) contributes to our general understanding of how a saturated hydrocarbon may be adsorbed on to the surface of a catalyst.

In the other approach, favoured by many

physical chemists, ways have been sought of achieving the direct partial oxidation of methane to methanol, ethylene and benzene. To date, such work has entailed the use of very high temperatures, and many of the more successful experiments have used nitrous oxide as oxidizing agent, which could never figure as conveniently as O_2 or air in any commercially viable process. In that respect, the use of O_2 as oxidant, reported by Ito and Lunsford in this issue[1], is a significant advance in the general quest to oxidize methane selectively. Moreover, the catalyst they use is devoid of transition metal ions, which have been thought to be necessary constituents of efficient catalyst formulations. The mechanism of activation at the active site (believed to be a Li^+O^- pair in the lithium-doped magnesia catalyst) probably entails the formation of methyl radicals.

Gas-phase kineticists and organic chemists have, over the years, recognized the mechanistic and preparative importance of free radicals in numerous categories of reactions. But for several decades past, the role of surface-generated free radicals in heterogeneous catalytic reactions, at least in the types of reaction studied by Ito and Lunsford, has been regarded as minor. Both the preparation of solids that facilitate the formation of reactive free radicals when hydrocarbon molecules impinge on their surfaces and the role of surface-generated free radicals will doubtless receive lively future attention in formulating new strategies for the mild oxidation of methane. □

Developmental biology

Homoeo boxes and strings for the packaging of genes?

from Brigid Hogan

NINETEEN eighty-four was a vintage year for developmental biology. The discovery of the 'homoeo box', first as a common feature of several developmental genes in *Drosophila*, and then as a highly conserved sequence in vertebrate DNA, has catalysed a lively fermentation of ideas from disparate areas of research. One outcome has been the isolation of mouse and human genes containing homoeo-box sequences. Now, on page 713 of this issue[1], Colberg-Poley *et al.* provide the first evidence that homoeo-box sequences are transcribed in mammalian cells: the fact that this transcription seems to peak transiently during the differentation of mouse embryonal carcinoma cells is bound to change some preconceived ideas about the function of mammalian homoeo-box genes, and opens up many new possibilities for experimentation.

As readers who have followed the story so far will know, the *Drosophila* homoeobox is a DNA sequence of about 180 nucleotides, discovered in at least five genes in the Antennapedia complex, three in the Bithorax complex and five outside these major gene clusters[2,3]. Mutations in specific homoeo-box containing genes can disrupt the normal pattern of segmentation either by causing a switch in segment identity (for example, from one carrying antennae to one carrying legs, in the case of *Antennapedia*) or by changing their number or anterior-posterior polarity. There is good evidence in *Drosophila* that homoeo-box sequences encode domains of proteins that are located in the nucleus and are possibly involved in DNA binding[4,5]. The general consensus, then, is that homoeo-box genes in *Drosophila* act in different combinations to select specific sets of genes defining unique properties of each of the compartments making up the larval segments. At least eight sequences closely related to the *Drosophila* homoeo box have been found in the mouse and human genome. In the case of the mouse gene described by Colberg-Poley *et al.*, there is a 95 per cent match between the amino-acid sequence that its homoeo box is predicted to encode and that of the homoeo box of the *Antennapedia* gene of *Drosophila*. Comparison of *Drosophila* and mammalian genes also points to similarities in, for example, gene clustering, 3′ intron/exon organization and the protein sequences beyond the strict confines of the homoeo box.

All this provides a strong impetus to search for a function for the mammalian homoeo-box genes. One approach is to test whether they are identical to any of the genes that, when mutated, cause mouse or human developmental defects. Already we know that one mouse gene is on chromosome 6 (the *Hox-1* locus)[6,7], and two groups[7,8] have recently assigned other homoeo-box genes to mouse chromosome 11 (*Hox-2*), and to the long arm of human chromosome 17 (*Hu-1* and *Hu-2*), near the loci for thymidine kinase, galactokinase and pro-α1 (I) collagen genes. These three genes have been mapped to chromosome 11 in the mouse (ref.8; K. Harbers and R. Jaenisch, personal communication) and it is reasonable to assume that *Hox-2* is close by. This brings within the range of speculation[8] the possibility that the gene at the *Hox-2* locus is identical to *Tail-short* (*Ts*), a gene that is lethal when mutant and homozygous, and maps close to thymidine kinase and galactokinase on mouse chromosome 11.

Fortunately for today's molecular biologists, many mouse developmental mutants have been the subject of much classical embryological and genetic study. Reference to the work of Deol[9] on the embryology of mice with one normal and one mutant *Ts* gene shows that although they develop many interesting skeletal abnormalities, early defects are also seen in non-segmented tissues, including a marked reduction in the number of blood islands in the extra-embryonic yolk sac. More recently, Patterson has described how mouse embryos that are homozygous for *Ts* die before implantation and can be dectected as abnormal even by the eight-cell stage[10]. So, if there is allelism between *Ts* and *Hox-2* (or another homoeo-box gene), at least one homoeo-box gene product is expressed at a very early stage and possibly in a wide range of tissues. Such speculation is not without foundation, as a homoeo-box gene of *Xenopus* is transcribed in the oocyte, and then again from the neurala stage at least up to the swimming tadpole[11].

Detailed studies on the transcription of homoeo-box genes in the mouse embryo will depend on good *in situ* hybridization data. Meanwhile, Colberg-Poley *et al.* have looked at transcription in F9 mouse embryonal carcinoma cells in culture. There are many tumour and embryo-derived cell lines now available, with a range of developmental potentials — from F9 cells, which hardly change at all unless treated with retinoic acid, to EK or ESC cells, which are difficult to restrain from differentiating into diverse cell types. Even when treated with retinoic acid, F9 cells give rise only to cells that express markers of extra-embryonic tissues, either visceral or parietal endoderm depending on the exact conditions[12]. In differentiating along these alternate pathways, the cells transcribe new sets of genes and switch off others. Colberg-Poley *et al.* find that a new 2.4-kilobase RNA, which hybridizes to their homeo-box probe, appears in F9 cells 17-24 h after the induction of differentiation; four days later this RNA is no longer present. The authors hint that RNA which hybridizes to the same probe is also present in normal mouse embryos, in both embryonic tissues and extra-embryonic tissues.

These results suggest that the pattern of mammalian homoeo-box gene transcript-

ion may be very complex and is not necessarily confined to specific regions of the embryo during the time when the serially repeated somite-derived tissues are being established, as might be expected by analogy with their expression in *Drosophila* embryos. Perhaps homoeo-box genes are needed for a much wider range of decision-making processes in mammalian embryos — unless, of course, they have nothing to do with development at all. For exploring these possibilities, F9 cells can be grown in large amounts so that cDNA libraries can easily be produced, and antibodies to fusion proteins used to try and isolate homoeo-box-containing proteins.

Such proteins promise to have extremely interesting properties. A possible homology between a 20-amino-acid subdomain of the homoeo box and the *MATa1* and *MAT α2* proteins of yeast, and the helix-2-turn-helix-3 region of known DNA-binding proteins such as bacteriophage λ Cro protein and *Escherichia coli* CAP protein, has been emphasized[4,13,14]. However, the rules governing prediction of three-dimensional structure from amino-acid sequence are not yet sufficiently refined for these homologies to be more than suggestive. Another motif of homoeo-box proteins is the presence of long strings of a single amino acid in regions flanking the homoeo box; repeats of glumatic acid (15 at the 3′ end of the clone described in ref. 1) glutamine, alanine and proline have been reported[1,4,15]. These strings may act as spacers between different domains of the protein designed for functions such as DNA binding, RNA binding or interaction with other regulatory proteins. Perhaps assemblies of boxes and strings act in various combinations to pack up DNA that is no longer needed, or to link new batches of active genes to the nuclear matrix. □

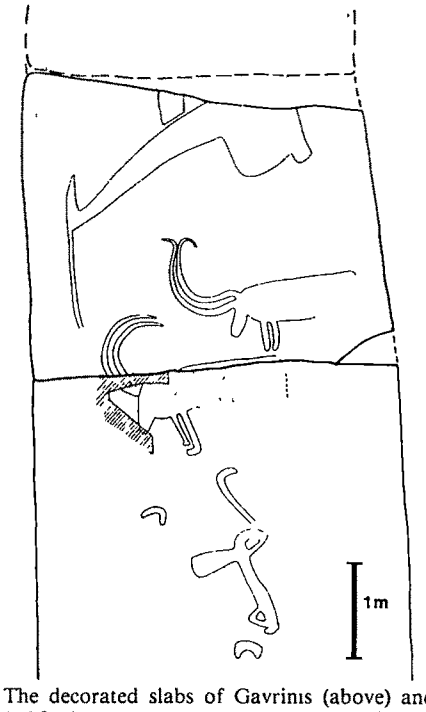
Archaeology

Megalithic recycling in Brittany

From Paul G Bahn

A REMARKABLE discovery made and recently published by C.-T. Le Roux[1] links two of the most famous megalithic monuments in Brittany — the tomb of Gavrinis, known for the superbly carved orthostats lining the passage, and the passage grave of La Table des Marchands at Locmariaquer, which also bears fine examples of megalithic art[2].

The underside of the capstone of the Table des Marchands (lower section of figure) has deep carvings of a beautiful hafted axe with two loops, a 'crook' and a couple of 'commas'. In addition, at the broken end, there are more lines which some observers have thought to be a "curious motif with a double crook"[2], whereas others saw them as part of a quadruped. Because part of this engraving is obscured by an orthostat, it has seemed likely that the slab formerly stood upright with its decoration clearly visible, but was then re-used. This hypothesis has also been made for the capstone of the tomb of Mané Rutual, which also has carving on its underside and is almost 12 m in length[3].



Le Roux's discovery has finally brought proof of this hypothesis. During restoration work on a capstone at the tomb of Gavrinis (now located on an island that was still linked to the mainland when these monuments were constructed), carvings were revealed on the upper side that had been invisible ever since the tomb's tumulus was set in place. The slab had clearly been dressed by man at the sides, and was broken at either end. Its carvings (central section of figure) comprised a great 'hache-charrue' (axe-plough), most of a horned animal and the horns of a second. Despite some resemblance to a mouflon or ibex, it is clear from the thick muzzle, short neck, straight back, angular rump and double-curved horns that a bovid is depicted.

The dimensions and grain of the rock, the shape of its break and the nature of its motifs all led Le Roux to link it with the Table des Marchands capstone. Sure enough, the two fragments would fit together, revealing a second bovid. Moreover, a similar rock used for a capstone in the long tumulus of 'er-Vinglé', just north of the Table des Marchands, was probably broken off from the other end of the Gavrinis slab (upper section of figure).

If so, the reconstituted stela would have stood about 14 m high, 3.7 m wide and 0.8 m thick, weighed about 100 tons and been decorated on the central portion of one face. It would have been second in size only to the Grand Menhir Brisé, 'er-Grah', which now lies in four fragments beside the Table des Marchands, and was over 20 m in length. It too was deliberately dressed and has an 'hache-charrue' carved on one of its fragments[2].

Because two of the three fragments of the 'new' stela are at Locmariaquer, it is likely that the block originally stood somewhere nearby, perhaps in the company of the Grand Menhir Brisé and the great carved endstone of the Table des Marchands. This means that the Gavrinis slab, of about 7.5 m^3 and weighing 20 tons, was transported 4 km (as the crow flies) across several water courses.

It has been suggested that the discovery implies a megalithic phase that preceded the tombs and involved great decorated stelae which, later, were deliberately thrown down and broken with wedges into fragments used in the building of tombs[4]; as the carvings were hidden to view at Gavrinis, they must have lost all significance. Le Roux is more cautious and envisages coexistence and complementarity of the menhirs and the tombs. Dating is not good enough to distinguish between the two possibilities. Gavrinis was perhaps built around 5,200-5,000 BP, and its use may have ended about 4,500 BP; but we have no idea when the stelae were put up or how long they lasted. Their decoration may provide proof of a very early use of the plough and of bovids for traction in the western-most part of Europe. But many questions about the history and function of these impressive but enigmatic monuments remain unanswered. □

The decorated slabs of Gavrinis (above) and Table des Marchands (below), as they would have fitted together (after C.-T. Le Roux).

Astronomy

A giant black hole at the centre of a dwarf galaxy

from C Martin Gaskell

THE dwarf elliptical galaxy M32, one of the satellite galaxies of the nearby spiral galaxy M31, has recently been shown to have a central dark object with a mass five million times greater than the Sun[1]. This is the most convincing case yet of a massive black hole in the centre of a galaxy.

Signs of violent activity are to be found in the nuclei of many galaxies. They range from modest goings-on in our own Galaxy to the tremendous outpourings of energy in quasars. The source of this energy is believed to be the accretion of matter onto massive black holes[2,3] but the evidence is still only indirect. One obvious way to detect a massive black hole is through its gravitational attraction on nearby stars. In 1978, the late Peter J. Young and his collaborators[4,5] claimed to have found just such an effect; in the very centre of the giant elliptical galaxy M87, the average speed of the stars shoots up dramatically, as though by sudden strong gravitational pull. M87 is certainly a galaxy in which one would expect a massive black hole because it is relatively active, but the claim soon came under attack. Theoretical studies[6-8] showed that the observations of Young and his collaborators[4,5] could be explained without invoking the presence of a black hole (of 5×10^9 solar mass) if the orbits of the stars were predominantly radial (rather than random). Further observations[9] showed a dense concentration of stars in the centre of M87, which also had to be taken into consideration. The presence of a black hole in M87 remains possible but is certainly not necessary.

M32 has perhaps a thousand times fewer stars than a giant elliptical galaxy like M87 and is certainly not an active galaxy. It does, however, show an unexplained concentration of stars towards its centre. Using the 200-inch telescope on Mt Palomar to study the motions of the stars in and near this central concentration, John Tonry has now found that, as with M87, the dispersion in the velocities of the stars rises suddenly towards the centre. But unlike M87, the system of stars as a whole is clearly rotating in M32, so radial orbits cannot be the explanation; there has to be some excess mass there. Moreover, this mass is more than can readily be accounted for by the stars alone; an extra five million times the mass of our Sun is present, according to Tonry. A massive black hole is the most likely explanation.

If there is a black hole of such size in the middle of M32, why is the galaxy totally inactive? The answer is probably that there is nothing to fuel the black hole; gas escaping from the galaxy rather than fal ing into the centre, as it would in a mor massive galaxy.

M32 is by no means unique in having dense central condensation of stars. It ju happens to be very near and is therefo easy to study. To make comparable obse vations on more distant examples will nee better resolution than can be achieved fro the ground. When the Space Telescope (di to be launched towards the end of ne year) turns on the nuclei of these galaxi I, for one, am pretty confident that the too will show signs of massive objects lurl ing in their centres.

Vision

Fireworks in the retina

from David I. Vaney

VISUAL information undergoes a sophisticated coding process in the retina, culminating in the diverse and functionally complex output of the ganglion cells to the brain. The receptive fields of the ganglion cells are shaped by the preceding interneurones, which include a set of neurones without axons, termed amacrine cells. The responses of amacrine cells are poorly documented because it is difficult to record from their small cell bodies, and the responses obtained may not reflect the local interactions between adjacent input and output synapses on the amacrine branches. In a recent series of elegant papers, however, R.H. Masland and his colleagues elucidate the functional properties of one small population of amacrines, those that contain acetylcholine[1]. Their findings suggest that the plexus formed by the branches of these cells provides the substrate for motion detection within subunits of a ganglion cell's receptive field.

In the rabbit retina, about four per cent of the amacrine cells synthesize and release acetylcholine. Their cell bodies are symmetrically distributed on both margins of the inner plexiform layer (IPL, the narrow zone containing processes of ganglion cells and presynaptic interneurones) and their terminals form two dense bands within the IPL[4,5]. These cells are of particular interest to retinal physiologists because they are implicated in the generation of direction selectivity in two types of ganglion cells[6]. Masland *et al.* have neatly side-stepped the problems of electrophysiological recording by studying the morphological characteristics and pharmacological responses of the whole population of these cells, using a sophisticated range of techniques. Although the shape and distribution of these neurones were presaged by previous studies[7-10] which used classical histological methods, this integrated approach provides definitive descriptions and fresh insight.

Masland, Mills and Hayden[1] hav shown that the acetylcholine-synthesizin amacrine cells identified by autoradio graphy are also selectively labelled *in viv* by the fluorescent dye diamidino-pheny indole (DAPI), so that the cells can b identified and mapped in a whole-mounte retina. Tauchi and Masland[2] have impale the DAPI-labelled cells with a micropipet under visual control and iontophoreticall injected the fluorescent dye Lucifer yello into the cytoplasm. This reveals a chara teristic dendritic morphology that has bee compared to a 'starburst' firework[9], an confirms the previous description by Vane using similar methods[11] (Fig.1). Th arborization ranges from 200-800 μm i diameter but is virtually planar, with th distal dendrites narrowly stratified in on of the two bands in the plexiform layer tha contain acetylcholine.

Masland, Mills and Cassidy[3] hav demonstrated that the two morphologic subtypes of cholinergic amacrines respon differently to visual stimuli; thos branching in the inner half (on the ganglio cell side) of the plexiform layer release transient burst of acetylcholine at light ON whereas those with branches in the oute half of the layer release a burst at light OF (Fig.2). This has been establishe convincingly by monitoring the distributio and release of labelled acetylcholine i response to visual stimulation *in vitr* while using a pharmacological agent know to block the transmission of ON response.

The most striking feature of the chol nergic amacrine cells is the extensive ove lap of their dendrites in the plexiform laye each point on the retina is covered by th dendritic trees of 25-70 cells of eac subtype[2,11], an order of magnitude greate than the overlap of the horizontal or gan lion cell arborizations in the cat retina[1]

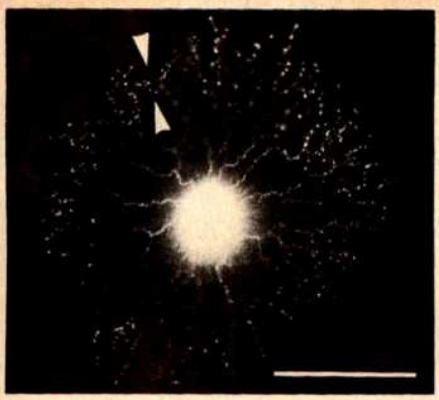

Fig. 1 Cholinergic amacrine cells in rabbit retina filled with the fluorescent dye, Lucifer yellow; the arborization in the inner plexiform layer is sharply focused beneath the blurred cell body. The characteristic appearance of these interneurones resembles a 'starburst' firework[9], an effect created by the numerous varicosities on the fine branches in the distal annular zone (between arrows). Scale, 100 μm. (Micrograph by D.I. Vaney).

Nearly all the output synapses of cholinergic amacrine cells are found on the varicose branches in the distal zone of the arborization, and make contact with ganglion cell dendrites[10]. Although the 50-80 terminal dendrites of a cholinergic amacrine are closely spaced in the plexus, a group of distal terminals may actually be separated from an adjacent group by a thin dendritic branch 200-800 μm long. Groups of terminals may thus be electrically isolated from each other and so form multiple subunits within a single arborization[12]. Tauchi and Masland[2] propose that the functional unit of cholinergic action is an aggregate of such subunits from overlapping dendritic trees. The transient local release of acetylcholine from these restricted regions of the plexus, at light ON and OFF, could provide the temporal and spatial resolution required for motion detection within the receptive field of single ganglion cells (Fig. 2).

The cholinergic plexus is so dense that there is a dendritic varicosity every few microns and, theoretically, the spatial resolution of the system could be as fine as the separation between varicosities. In practice, however, the resolution of the cholinergic plexus is limited by the less dense mosaic of presynaptic bipolar cells,

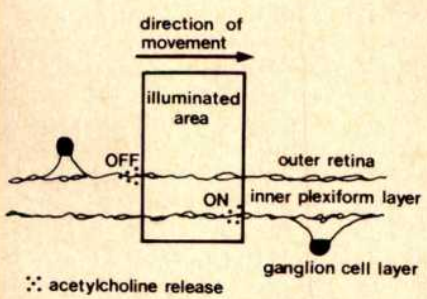

Fig. 2 Local release of acetylcholine from amacrine cell terminals in response to a moving stimulus (modified from ref.3).

which makes the overlap of branches appear curiously redundant. Moreover, dendritic replication seems a cumbersome way of producing transmitter amplification "capable of powerful local action"[2]. Such arguments assume that the cholinergic amacrines are functionally equivalent, but this need not be the case[3]: one scheme for producing direction-selective (DS) receptive fields in ganglion cells requires that the cholinergic subunits are anisotropic[6].

DS ganglion cells respond with vigorous excitation when a stimulus is moved through the receptive field in the preferred direction, whereas motion in the reverse ('null') direction inhibits them, evoking little or no response[13]. The ON-OFF DS units in the rabbit retina form four groups, each with a range of preferred directions that does not overlap the other groups. Cholinergic amacrines provide substantial direct input to DS ganglion cells and, if potentiated by the cholinergic agonist physostigmine, their excitation can overcome the null-direction inhibition[6]. It is not known, however, whether the nonlinear interactions between the excitatory and inhibitory inputs take place in the ganglion cell itself or in the presynaptic neurones. In the latter case, the release of acetylcholine would itself be directionally selective. DS ganglion cells in one group may thus receive cholinergic input from different subunits to those in the other three groups, and this would further rationalize the great overlap of the cholinergic amacrine cells.

The apparent simplicity of directional selectivity has seduced retinal physiologists for over twenty years but its mechanism still eludes them. The advances made by Masland and his colleagues provide new tools for dissecting the phenomenon and suggest that satisfaction is now within reach. □

Tectonics

Whence British Columbia?

from E. Irving

IDEAS about the origin of the western cordillera of North America are undergoing an evolution that resembles, in miniature, that which occurred in global tectonics about 30 years ago, when mobility replaced fixity as the basis for geological thought. The palaeomagnetic measurement of very large displacements among continents in the mid-1950s was followed by a decade of scepticism, until evidence from the oceans made the case for global mobility unnassailable. Similarly, measurements in the early 1950s of very large displacements in deformed belts within the confines of a modern continent met a large measure of disbelief; the orthodox view was that mountain belts were formed more or less where they are now. In the North American context, attitudes soon changed as geologists came to realize that the western cordillera was made up of a patchwork of dissimilar blocks which came together in the mid-Mesozoic (150 – 100 Myr ago) from sundry and not accurately known places. The notion of mobility therefore began to be accepted in a loose qualitative sense.

Recently, geologically young displacements have been found further and further eastward in the cordillera, especially in the Canadian sector, as if the assembled patchwork of blocks had moved northwards as a whole minicontinent during the Laramide Orogeny (80 – 50 Myr ago), when the Rockies formed. This turn of events has not been received with enthusiasm by geologists because they see little or no evidence for it in the rock record. However, it is possible that much of the direct evidence for this massive event has been obscured by deep blind thrusts, as yet unrecognized, along which large-scale horizontal transport has occurred. Rather than investigate the suggested movement of the western minicontinent, most workers have focused on easier problems concerned with its earlier assembly — with local rather than regional geology. Chamberlain and Lambert in their paper on page 707 of this issue[1] step back from the local scene and try to describe the Laramide event in its entirety.

Their scheme is based on two premises. First, the assembled minicontinent (dubbed by them 'Cordilleria', although I would have preferred the more accurate name 'Baja British Columbia' following Stone's[2] terminology) was situated much further south than at present, as indicated by palaeomagnetism[3,4]. Second, Cordilleria was driven northwards because it was attached to an oceanic plate[2], the Kula Plate[5].

Within this general kinematic framework Chamberlain and Lambert envisage two stages. To begin with, there was an interval of closure as Cordilleria moved from somewhere offshore in the Pacific Ocean towards mainland North America, a small oceanic

basin being consumed between them. Geological evidence for this lost ocean is to be found, according to Chamberlain and Lambert, in granitoid rocks formed when the oceanic crust melted as it sank beneath Cordilleria. They argue that the volcanoes that formerly surmounted these granitoid bodies were responsible for the first appearance of airborne volcanic ash in the Alberta Basin to the east about 100 Myr ago. I cannot comment on how well their proposal agrees with the geological evidence, but it does not agree with palaeomagnetism, according to which Cordilleria, at that time, was as much as 2,000 km south of Alberta[6]. Moreover, it could not have moved so early if, as Chamberlain and Lambert argue, it moved with the Kula Plate, because the latter did not form (by splitting from the Farallon Plate) until 85 Myr ago[7]. Cordilleria actually began its journey after Chamberlain and Lambert suppose it to have arrived; this does not disprove their scheme, but means only that the timing needs revision.

During the second envisaged stage, Cordilleria has reached mainland North America and procedes to slide sideways (strike-slip motion) along the Rocky Mountain Trench. It is this trench that Chamberlain and Lambert choose as the present-day boundary between Cordilleria and North America. The trench is a linear series of narrow valleys situated west of the Rocky and Mackenzie Mountains and stretching some 2,000 km from the Alaskan border, through Canada and south to the continental United States.

There is evidence of up to 1,000 km of motion along or close to the northern part of the trench[8] but across the southern trench there are similarities in Phanerozoic rocks that have usually been taken to preclude strike-slip motion. Chamberlain and Lambert regard these similarities as superficial and the consequence of wholesale Laramide thrusting across the trench, which has obscured the deeper break. In their search for this break, they point to the Proterozoic Malton gneiss complex, located astride the southern trench. They claim to have demonstrated geochemical and age differences between rocks of the complex to the east and west of the trench, and argue that the trench is a window of disrupted basement rocks exposed through overlying Laramide thrust-sheets. The earlier interpretation — that the malton gneiss 'locks' the trench, denying motion along it — is neatly turned on its head, so that it becomes evidence for motion rather than against it. Geochemists will want to see the analyses and structural geologists will wish to reassess the disposition of these remote rocky outrops, but the argument is arresting, and not lightly set aside.

I am glad that Chamberlain and Lambert have grasped this nettle. It is not difficult to pick holes in their scheme (it could hardly be otherwise with so complex a problem) but they are certainly looking at the problem in the correct way. Theirs is a useful and timely contribution which will assist discussion of the nature of the Laramide Orogeny. □

Genetic screening

The heredity of haemophilia

from Miranda Robertson

GENE therapy is not yet a reality. But the technology that may one day make possible the molecular repair of genetic defects is already providing a range of diagnostic and screening tools that must complicate the task of genetic counselling even as they widen the choice open to the parents of a potentially defective child. The easiest kind of genetic disease to detect by molecular means is one in which the defective gene is known and the rate of spontaneous mutation is low. This is the case for some of the hereditary anaemias, for some of which it is now possible to make gene probes that will distinguish a mutant from a normal globin gene even where the disease is due to a single point mutation. The case of haemophilia, in which the defective gene is also known and has recently been isolated and cloned, is more complicated, as a report from Gitschier *et al.* on page 738 of this issue clearly shows[1].

The commonest form of disease is haemophilia A, which affects about one individual in 10,000. The defect is in the gene encoding factor VIII, one of the cascade of plasma proteins that interact in blood clotting: haemophiliacs die from internal haemorrhage unless treated wth exogenous factor VIII. The gene for factor VIII is on the X chromosome, so usually only males are affected, females being protected by the normal gene on their second X chromosome. Females may thus be symptomless carriers: a woman whose father is haemophiliac is of necessity a carrier of the gene; one whose brother or uncle is haemophiliac may be. Treatment with factor VIII from donor plasma is effective but carries the risk of hepatitis and more recently — but very rarely — of acquired immune deficiency syndrome (AIDS); moreover about 15 per cent of haemophiliacs develop antibodies to the replacement factor VIII.

In the circumstances many female carriers would rather have an abortion than an affected child. Factor VIII, however, cannot be assayed in an unborn child until 18-20 weeks into pregnancy, and in the absence of any way of distinguishing the mutant from the innocent maternal X chromosome, some carriers have opted for early abortion of all male fetuses, accepting the 50 per cent chance that a normal child will be destroyed.

The announcement late last year that the gene for factor VIII had been isolated, characterized and cloned[2,3] opened up the possibility of precise identification of the gene defect and, with it, reliable detection of carriers and accurate prenatal diagnosis within the first 8-11 weeks of pregnancy, when abortion is safer and less traumatic. As it turns out, however, the factor VIII gene is proving less cooperative than might have been hoped.

Ideally, a mutant gene is distinguished from a normal one by a radiolabelled DNA probe that detects the mutation itself. In practice, this is really only applicable where a few identified mutations have spread through a population and probes can be tailored to each of them; where a high incidence of genetic disease is due to a high rate of spontaneous mutation, the molecular defect may be different for each affected family. This now seems to be the case for haemophilia A[4]. Moreover, as a point mutation can disable the factor VIII gene as effectively as a major deletion[4], relatively gross screening, which would only pick up a truncated gene, will miss many defects whose consequences are severe.

The alternative to direct detection of the mutation is to identify the mutant gene in individual families by means of natural sequence variations (polymorphisms) present in the population as a whole. Such polymorphisms have no effect on the function of the gene, and simply serve as markers by which one factor VIII gene can be distinguished from another. Gitschier *et al.* have discovered such a polymorphism in the factor VIII gene, and have been able to use it in carrier detection.

As a screening tool, detection of polymorphisms has several grave disadvantages by comparison with direct detection of mutations. First, because any given polymorphism may be present in perfectly normal genes as well as the mutant gene, accurate diagnosis means having enough pedigree information to establish which polymorphic variant of the gene carries the haemophilia mutation in a given family. Given adequate pedigree information, the value of a polymorphism will then depend on two more factors. The first is the number of polymorphic variants — usually there are only two; and the second is their frequency in the population at large. If there are only two variants (say, I and II) and one of them (say II) is infrequent, then a particular carrier is quite likely to be homozygous — that is, both her factor VIII genes are likely to be variant 1, although

only one of them will contain the mutation; the polymorphism will then be uninformative. (In the case of autosomal defects — where the mutation is not on the sex chromosomes — the position is further complicated by the possibility that the father may also carry the polymorphism in a normal gene; but this problem does not arise in X-linked diseases such as haemophilia because a boy inherits only one X chromosome, from his mother.)

Polymorphisms are most easily detected by bacterial enzymes (restriction enzymes) that cut DNA at specific sequences. A variation in the target sequence will prevent the enzyme from cutting at that point, and change the sizes of the fragments into which the gene is cut by the enzyme. Gitschier *et al.* experimented with 37 restriction enzymes, and found only one polymorphism in the 90,000 base pairs of the factor VIII gene that they searched[1]. This is, as they point out, remarkably low compared with, for example, globin genes. The polymorphism that they did find is revealed by the restriction enzyme *Bcl*I, and has two alleles, present at roughly 70 and 30 per cent in the population. This makes it reasonably informative: five of eight tested carriers were heterozygous.

Much more informative, however, is the polymorphism recently reported by Oberle *et al.*[5]. It lies outside the factor VIII gene itself but is in the DNA that flanks the gene and so is usually inherited with it. Termed St14, the site has 10 polymorphic variants.

The disadvantage of this marker, as with any linked marker, is that genetic recombination can occasionally separate the marker from the gene giving a false result in a screening test. Nevertheless, St14 and *Bcl*I combined with another linked marker, DX13, provide a powerful genetic screening tool in those families where the necessary pedigree data are available.

Even with routine screening, given the high rate of *de novo* mutation and the existence of a normal carrier state, haemophilia A is not going to disappear from human populations. There is much talk of using genetically manipulated bone marrow to correct genetic defects where, as in haemophilia, the site of action of the gene is the plasma. This would entail the introduction of a normal factor VIII gene into the patient's own bone-marrow cells, which do not normally express the gene. At this stage, such therapy could not be justified in the face of unknown risks, for a disease treatable by more conventional, albeit imperfect, means. Nor is it clear whether the problem of antibody production against factor VIII could be avoided, for instance by very early bone-marrow therapy. In all likelihood, we shall see.□

Mathematics

Feigenbaum's fixed function

from Ian Stewart

FOR several years there has been a flurry of activity on the topic of 'deterministic chaos' whereby quite simple systems, described by equations having no explicit random terms, nevertheless exhibit behaviour that seems to be stochastic. Using ideas from renormalization group theory (originally invented to handle problems in quantum field theory), Mitchell Feigenbaum of Cornell University was led to conjecture some very specific 'universal' properties of such systems. Feigenbaum's conjecture was proved in full rigour by M.Campanino, H. Epstein and D. Ruelle (*Commun. math. Phys.* **79**, 261; 1981 and *Topology* **21**, 125; 1982) and by Oscar Lanford (*Bull. Am. math. Soc.* **6**; 1982). Both proofs made heavy use of complicated (though exact) numerical estimates, which required computer assistance. Remarkably, Lanford — who works at the Institut des Hautes Etudes Scientifiques in Bures-sur-Yvette — has now improved the proof so that only a calculator is required.

Feigenbaum's conjecture arose from a numerical study of the behaviour of the nonlinear recurrance equation $x_{n+1} = kx_n(1-x_n)$, as the constant k increases from 0 to 4. An initially stable fixed point bifurcates into a pair of points of period 2, which in turn split into periods 4,8,16,... and so on. By the time k reaches a value around 3.7, an infinite number of these bifurcations has occurred; this is called a period-doubling cascade. Such cascades are of interest in a variety of applications, notably fluid turbulence. Feigenbaum was interested in the rate at which successive steps in the cascade developed. Let k_n be the value of k at which the nth period-doubling occurs. The ratio of gaps between consecutive bifurcation points is $\delta_n = (k_{n+1} - k_n)/(k_{n+2} - k_{n+1})$; as n tends to infinity the value of δ approaches 4.6692016.... That is, the successive bifurcation points accumulate according to a geometric progression at a rate measured by δ. On repeating the calculation for other nonlinear recurrence equations, Feigenbaum discovered that the values of δ were identical. This coincidence has important implications for experimental confirmation of mathematical models based on nonlinear recurrence equations (discrete dynamical systems), because by observing the values of k at which the first five or six period-doublings occur, one may obtain an experimental estimate for δ, to be compared with a very precise theoretical prediction.

Further investigation suggested a reason for the 'universality' of δ. If $f(x) = kx(1 - x)$ is the function being iterated in the recurrence equation, then it turns out that the second iterate $f^2(x) = f(f(x))$ has almost the same shape of graph as f, provided the axes of the graph are similarly positioned and sealed, and provided attention is confined to a suitable range of values of x. The clue to the universality lies in finding a function g for which this scaling process is exact. In other words, g must satisfy the Feigenbaum-Cvitanovic functional equation

$$g(x) = -g(g(-ax))/a$$

for a positive constant a (representing the required scale factor). The difficulty is to show that such a function g exists.

To do so, one starts with a function that satisfies this equation to a very high degree of approximation and uses it to construct a sequence of functions, by a process of renormalization, that converges to the desired solution. Abstractly one thinks of the desired g as living in a space X of functions: the renormalization operator T transforms any function h in X into a new function Th. The operator T is chosen so that the Feigenbaum-Cvitanovic equation boils down to the requirement that g be a fixed point (or fixed function) of T. Standard theorems, concerning fixed points of operators on function spaces, then finish the proof.

The difficulty is to obtain a sufficiently close initial estimate. It is here that the computer comes in. Although in the normal run of things the numbers held in a computer are subject to rounding error, it is possible to keep track of the largest size such errors can be, and hence keep exact estimates of the degree of accuracy of the calculations. In the present case, the initial choice of function h is somewhat complicated and so, therefore, are these estimates.

Lanford has succeeded in simplifying the procedure to the point at which the estimates may be performed using a hand-held calculator (here a Hewlett-Packard HP-15C, accurate to nine decimal places). The proof remains delicate, but is much simpler than its predecessors. Note, however, that to apply g to period-doubling, some additional properties must be established, which can still only be obtained using Lanford's computer-assisted proof.

The essence of the problem seems to be that the Feignenbaum fixed function g cannot be related in any very direct way to more standard functions, such as polynomials, for which methods of calculation can easily be found. Functional equations themselves have been something of a mathematical backwater. The prospect of applying them to nonlinear dynamics now makes it important to develop new and better techniques to handle their solutions. In such a way may new mathematics be born from a good physical problem. □

Mushroom cloud the result of a meteor?

SIR — On 9 April 1984, a number of airline pilots witnessed a mushroom cloud above the northern Pacific Ocean, about 400 kilometres off the east coast of Japan. The cloud was first witnessed by the pilots of Japan Airlines flight JAL 036 at 14:06 GMT (23:06 local time) while flying route A-90 eastbound near the checkpoint PAWES. The location of the first sighting was 38.5° N, 146.0° E. The pilot reported that a large spherical cloud rose from the cloud deck below his aircraft and expanded rapidly to its full height of 60,000–70,000 feet and its full diameter of 200 miles in something between 1 min 50 s and 2 min 30 s. There was a heavy deck of clouds at the 14,000 feet level, but visibility was fair because of moonlight. About 12 s later, near 42° N, 151° E, they felt light turbulence. JAL 036 dispatched a May-day call at 14:21 GMT, put the crew on oxygen, and descended. JAL 036 was diverted to Elmendorf Air Force Base in Anchorage, Alaska, where radioactivity tests were conducted, but no trace was found. There was no communications breakup, nor any problems with the aircraft instruments.

Radioactivity tests conducted on other aircraft reporting the cloud also found no trace. Subsequent interviews with those pilots showed that the cloud exerted no fireballs or flash of lights. However, slight luminosity of the cloud was reported by several pilots. The pilot of KLM 868 reported that at first the cloud was opaque, then as it got larger it became possible to see stars through it. The phenomenon was visible for about 55 min.

The event was investigated by the US Department of Defense, Japanese Defence Agency, Federal Aviation Administration (FAA) and many others. All investigations concluded that it was not a nuclear explosion and it was possibly a natural phenomenon, but they failed to give a reasonable explanation.

We have investigated the event by querying FAA pilot interviews, newspaper reports, weather satellite photographs, and geophysical data from various institutions. Geophysical data include seismic, hydrophone, atmospheric electricity, telluric current, geomagnetic, and microbarograph data. However, none of the data we have studied contains a detectable signal from this event. Measurements of SO_2 in the ozone layer made by the National Aeronautics and Space Administration were also negative, suggesting that it was not a volcanic event.

We also obtained comment and opinions from experts in various related fields about this event. Some of the possible explanations we have pursued are:

(1) A gaint cumulus cloud.
(2) A vapour plume from the Kaitoku Seamount, 1,500 km south-west of the event.
(3) Burning of rocket fuel causing the ionization of cloud particles and the subsequent formation of a plume.
(4) A meteor causing the ionization of cloud particles and subsequent formation of a plume.

Of these possibilities, we have concluded that only the meteor plume has sufficient energy to explain the event. Meteors can enter the Earth's atmosphere at almost any angle. The speed of a meteor ranges from 15 to 110 km s^{-1}, and its height ranges from 150 km to ground level. Meteors slow down considerably upon entering the Earth's atmosphere. Normally, when a meteor does reach the ground as a meteorite, it travels the final portion of its trajectory as a dark body; it is rarely luminous below heights of 10 to 20 km.

A meteor's energy is very high. For example, the muzzle velocity of a 30-calibre bullet is about 840 m s^{-1}. A meteoroid the weight of a bullet (10 g), entering the lower atmosphere at a speed of 30 km s^{-1} has as much kinetic energy as a bullet leaving a muzzle. At this speed, even cloud particles striking at the surface of the meteor can produce a shattering effect. Collisions with atmospheric particles ionize atoms and produce visible luminosity.

Our hypothesis is that a meteor encountered the cloud deck and almost simultaneously shattered into pieces. Most of the kinetic energy was converted to heat which evaporated cloud particles, and the hot gas formed a plume. Because of the high speed of the meteor, the shattering took place over a distance spanning a few tens of kilometres, thus forming a large plume. The large distance over which the shattering occurred explains why only a slight disturbance was felt by the pilot and why microbarographs in Japan failed to detect the signal. It explains why there was neither a fireball nor a flash of light associated with the event; and it also explains the slight luminosity of the mushroom cloud.

If our explanation is correct, the pilot's experience on the night of 9 April may be the first close encounter of an aircraft with a meteor. We would welcome readers' comments on this event.

A mechanism for prion replication

SIR — The putative causative agents of some infectious diseases which attack the brain, such as Creutzfeldt-Jakob disease of man and scrapie of sheep, have been called[1] 'prions'. Prions consist of protein, and apparently they contain no nucleic acid[1], although this contention has been challenged[2]. As reviewed recently in News and Views[3], two alternative mechanisms have been proposed for the replication of prions. (1) Activation of transcription of a host gene coding for prion protein. (2) 'Reverse translation' or protein-directed protein synthesis. There is no direct evidence for either of these mechanisms and therefore the replication of prions remains an enigma, although possible mechanisms for self-replication of proteins have been proposed[4].

We wish to propose an alternative possible mechanism for the replication of prions, which could operate if prions are indeed devoid of nucleic acid.

Prions consist of a single major protein component called[5] PrP, of relative molecular mass 27,000-30,000. We propose that PrP is a very stable slow-acting proteolytic enzyme, which may produce brain pathology precisely because of its protease activity. We further propose that the mechanism by which PrP 'replicates' is proteolytic attack of a precursor protein (which we call pre-PrP) present in many cells, and certainly in the brain, having an as yet unknown normal function. This precursor is folded in a configuration that has no proteolytic activity but, being a 'substrate' of PrP, it can be proteolytically cleaved with production of a fragment (or domain) which is PrP itself. The newly released PrP is then able to digest other pre-PrP molecules, thus bringing about multiplication of an apparent 'infective agent'. This proteolytic multiplication is reminiscent of other well-known cases in which a proteolytic enzyme (such as pepsin) acts on a precursor (such as pepsinogen) splitting off a portion to yield more of the same active protease.

The model we propose is consistent with the 'autocatalytic' time course of the diseases in question, in which there is a long incubation period followed by rapid disease progression. Moreover, the prior existence of pre-PrP in the body would account for lack of immune response (characteristically observed in these diseases), and ought to be detected also in normal cells, either directly or through its messenger.

We hope experiments will be devised to test this hypothesis, which may have relevance to other so-called 'slow infections' and degenerative diseases of the brain.

Biology Titles from Croom Helm

MICROFUNGI ON LAND PLANTS: An Identification Handbook

Martin B. Ellis, *formerly Principal Mycologist, Commonwealth Mycological Institute, Kew, and* ***J. Pamela Ellis,*** *formerly of Nottingham University*

For amateurs and professionals alike, this book will be an indispensible reference work, enabling the identification of 3,300 microfungi. It is thus a landmark in the mycological literature, featuring numerous keys and 2,000 original drawings, many from specimens collected by the authors.

£45.00 hbk 0-7099-0950-0 816 pages April 1985

THE MOLECULAR BASIS OF CANCER

Edited by Peter B. Farmer, *MRC Laboratories, Carshalton and* ***John M. Walker,*** *Hatfield Polytechnic*

This is a text providing state-of-the-art descriptions of our knowledge of cancer at the molecular level. Dealing with causative agents, methods of cancer detection and treatment, it will be of use to undergraduates, medical students and postgraduates entering cancer research.

£25.00 hbk 0-7099-1044-4 352 pages
£12.95 pbk 0-7099-1068-1 March 1985

EVOLUTIONARY THEORY: The Unfinished Synthesis

Robert G.B. Reid, *Department of Biology, University of Victoria, Canada*

This book proposes a holistic approach to evolutionary theory. It evaluates the modern and historical alternatives to Darwinism, stresses the importance of the individual organism in the evolutionary process and explains the evolutionary significance of associative and regulatory changes.

£25.00 hbk 0-7099-2282-5 416 pages June 1985

THE BIOLOGY OF MUTUALISM: Ecology and Evolution

Edited by Douglas H. Boucher, *Department of Biological Sciences, University of Quebec at Montreal*

This book discusses mutualism from theoretical standpoints which may be applied to many different organisms and ecosystems. The ecological importance of mutualism is demonstrated and a variety of ideas are developed to provide a text of interest to biologists and ecologists.

£37.50 hbk 0-7099-3238-3 400 pages June 1985

DIET-RELATED DISEASES: The Modern Epidemic

Stephen Seely, David L.J. Freed *and* ***Gerald A. Silverstone,*** *University of Manchester, and* ***Vicky Rippere,*** *Institute of Psychiatry, London*

A likely cause of lethal diseases such as arterial disease and some cancers, plus non-lethal complaints such as asthma, migraine and allergies, is the diet. This book reviews the ways in which diet can cause or aggravate illness, with emphasis on the mechanisms of pathology.

£19.95 hbk 0-7099-3364-9 288 pages
£ 9.95 pbk 0-7099-3365-7 April 1985

FISH ENERGETICS: New Perspectives

Edited by Peter Tytler, *Department of Biological Sciences, University of Stirling, and* ***Peter Calow,*** *Department of Zoology, University of Sheffield*

Aspects of fish energetics are explored through the main theme of adaptational aspects of energy budgets, evaluated in terms of metabolic costs and fitness benefits of component processes. Of interest to physiologists, ecologists and evolutionists and applicable to fisheries and aquaculture.

£27.50 hbk 0-7099-3410-6 352 pages April 1985

FISH ENDOCRINOLOGY

Allen J. Matty, *Department of Molecular Sciences, University of Aston*

As an up-to-data account of fish endocrine glands, their products, and roles in physiology, form and behaviour, movements and migration, this book will be of interest to biology students and fish research workers. It includes a review of the applied use of hormones in fish farming and aquaculture of particular relevance to the fish-farming biologist.

£22.50 hbk 0-7099-1729-5 272 pages June 1985

THE BIOLOGY AND MANAGEMENT OF MOUNTAIN UNGULATES

Edited by Sandro Lovari, *Institute of Zoology, University of Parma*

This book presents original material on the biology and management of most Eurasian mountain ungulate species. Half the book deals with chamois, the commonest species, and there are chapters on conservation of endangered species. It will be of interest to vertebrate zoologists and those with an interest in mountain wildlife.

£25.00 hbk 0-7099-1688-4 288 pages April 1985
20 half-tones

ENVIRONMENTAL STRESS AND BEHAVIOURAL ADAPTATION

John Davenport, *Marine Science Laboratories, University College of North Wales*

A student text which describes and evaluates those facets of behaviour which allow animals to minimise the effects of environmental stress. While covering a range of animals, the text describes the effectiveness of the behaviour, energetic costs, homeostasis and the evolution of the behaviour via apparent selection pressures.

£14.95 hbk 0-7099-0829-6 128 pages
£ 6.95 pbk 0-7099-0854-7 December 1984

GENE MANIPULATION AND EXPRESSION

Edited by Robert E. Glass, *Department of Biochemistry, University of Nottingham, and* ***Jaroslav Spizek,*** *Czechoslovakian Academy, Prague*

This is a collection of papers on prokaryotic gene expression and manipulation from a symposium held in Bechyne, Czechoslovakia, in 1984. It will interest researchers in prokaryote molecular biology, microbial genetics and genetic engineering.

Prov. £30.00 0-7099-3818-7 300 pages July 1985

THE EVOLUTION OF MAMMALIAN CHARACTERS

Doris M. Kermack, *Imperial College, and* ***Kenneth A. Kermack,*** *University College, London*

'Every teacher of vertebrate palaeontology will long be grateful to the Kermacks for this scholarly essay and there will be many a teacher of palaeontology who will now acquire the courage to lecture on Mesozoic mammals once armed with this volume.' *Geology Magazine*

£15.95 hbk 0-7099-1534-9 160 pages 1984

PRINCIPLES OF ECOLOGY

R.J. Putman *and* ***S.D. Wratten,*** *University of Southampton*

'This is an excellent book, well set out and relatively easy to follow without making a great number of assumptions about the reader's previous knowledge of the subject... This book would be a useful text for undergraduates and lecturers alike and represents a comprehensive and modern analysis of the field.' *Habitat*

£22.50 hbk 0-7099-2016-4 383 pages
£10.95 pbk 0-7099-2050-4 1984

FISH MIGRATION

Brian A. McKeown, *Simon Fraser University, Canada*

A major review of fish migration of interest to workers in animal behaviour, behavioural ecology and fisheries. It covers various patterns of migration, orientation and navigation, energy costs, physiological adaptations, and ecological and evolutionary aspects of migration.

£19.95 hbk 0-7099-1761-9 240 pages 1984

MEDICAL AND VETERINARY ENTOMOLOGY

D.S. Kettle, *formerly of the University of Queensland*

This is a definitive and comprehensive text for advanced students of zoology, tropical medicine and veterinary science: a major reference for professionals in both pure and applied entomology.

£27.50 hbk 0-85664-839-6 664 pages 1984

The ragged edge

Reflections upon what is to be found in books, besides the text.

DR JOHNSON said about cucumbers that they should be well sliced, and dressed with pepper and vinegar, and then thrown out as good for nothing. This is more or less what happens when scientific information of similar insipidity is processed into books, that are catalogued and at once fade, all but a few of them, from human consciousness. To browse among the review copies that each week fill some yards of shelf space in offices of journals such as this quickly induces a desolating sense of the futility of man's endeavour. Who will actually read this tome containing the *Proceedings of the Fifth Annual Conference on Isoelectric Focussing in Polyacrylamide Gels*? Will the narrative perhaps go with more of a swing than the sinking feeling in one's viscera portends? It will not. It will be what Lewis Carroll subtitled *The Hunting of the Snark* — an agony in five fits. Why do they do it then, those battalions of authors and editors? I think it was a historian who defined research as reading two books that have never before been read in order to write a thesis that will also never be read. Perhaps Byron hit the nail on the head:

'Tis pleasant, sure, to see one's name in print;
A book's a book, although there's nothing in't.

There is material here from which more than one PhD thesis could be hewn. If there is little pleasure or improvement to be had from the texts of most books, can we find it elsewhere between the covers? There is not much fun in the index, the contribution all too often, it seems, of the author's wife. The best one can hope for is a diverting typo or two: what for instance are these congenial metabolic diseases to which this one keeps referring? And what are the particular virtues of freeze-frying? But no, there are more abundant pickings for the sociologist of science nearer the title page. The dust-flap of course often yields a morsel for the connoisseur. Here is one that comes to me at second-hand, by way of the *New Yorker*; it commends the book, a dictionary, gift bound in tooled cowhide, and notes that it is "alphabetized for easy reference". Good idea, comments the *New Yorker*. But it is more likely that you will merely be assured that you hold in your hand an integrated wide-parameter, in-depth state-of-the-art overview, that will enable the student to digest this seminal cornerstone of a rich and pregnant field; it will set new benchmark standards as a very nearly unique quantum jump, an indispensable framework, comprehensive yet concise, directed as much at the specialist research worker as at the undergraduate, and essential reading for astronomers, cytologists, palaeontologists, cytopalaeoastronomers, palaeocytologists and astropalaeontologists. But since the credit for such gems of the blurb-writer's craft cannot be laid on the author, let us start at the beginning with the epigraph. This may be in Latin or even Greek (in which the author does not have to be fluent), but if in English it should preferably be totally inscrutable. Thus: "A philosopher does not need a torch to gather glow-worms by at mid-day" — Ernest Bramah.

There follows the preface with a list of acknowledgements in which wives and family feature by reason of their fortitude in sharing for several weeks the ardours of a scribe's life. More particularly, wives without exception have typed the manuscript, compiled the index, read the proofs or supplied candid and perceptive criticism. How many such wives are wives still by the time the book is in print? The late Queenie Leavis was said to have discovered only on publication that she was not co-author of one of her husband's blockbusters. There has been a rash of lawsuits in recent years, from which emerged sorry stories of help-meets, who not only filled fountain-pens, typed manuscripts and cooked meals, but also earned money to see the husband through his PhD and were then returned to store for their pains. The scientific wife is a social species ripe for a PhD of her own.

It is customary for the author also to render thanks to a colleague or two for critical reading of the text; it would be an almost indecent breach of tradition not to conclude with the arch avowal that what errors remain are his — but the implication is that they are his friends' just the same. (As Charles II said in response to Rochester's famous mock-epitaph, "He never said a foolish thing/Nor ever did a wise one" — his words were his own, but his deeds were his ministers). There is then much citing of sources from which material has been gouged. I have only once seen a trickle of bile, such as many authors must have suppressed with difficulty; it comes from Jonathan Gathorne-Hardy's splendid treatise on the British nanny: "I must also formally acknowledge the following publishers, institutions and people for their permission, often after substantial payment, to quote from the books whose copyright they control...". The sycophantic expressions of gratitude to patrons have alas largely vanished, for the realization has grown that institutions, even those as munificent as the National Institutes of Health, have no mechanism for receiving homage or converting it into gratification. To thank the NIH has always seemed to me a little like the action of the small boy who was observed by the Reverend Sydney Smith to be stroking the shell of a tortoise in order, as he said, to please the creature; "why", said Sydney Smith, "you might as well stroke the dome of St. Paul's to please the Dean and Chapter". More entertainment was to be had from writers' relations with patrons of an earlier age. Dr Johnson's dissatisfaction with Lord Chesterfield's performance in the office is recorded in the *Dictionary*, in which he defines a patron as "one who countenances, supports or protects. Commonly a wretch who supports with insolence, and is paid with flattery". He enlarged on this in his celebrated letter to Chesterfield, in which he drew the parallel between the patron and one who observes the struggles of a drowning man and only when he reaches the shore encumbers him with help. Analogies in the support of modern science suggest themselves.

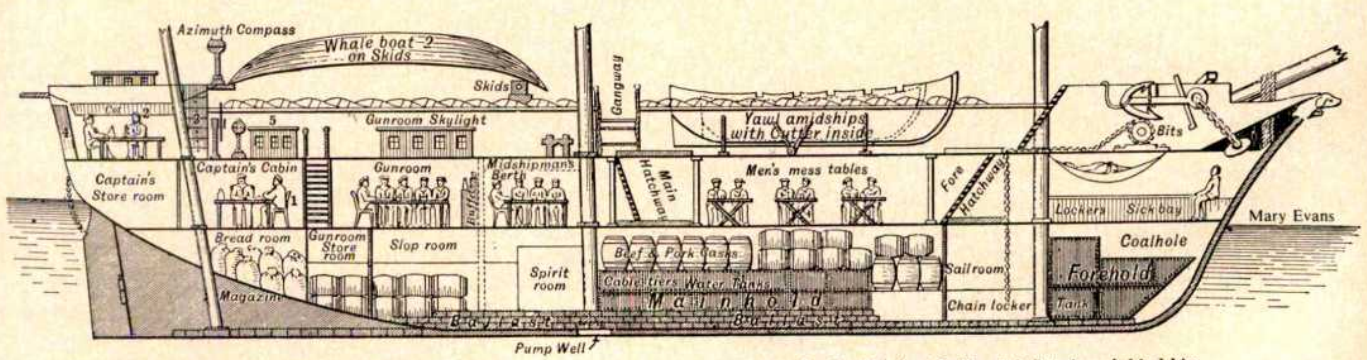
Not the least of the author's problems is the dedication. A spouse, mistress or auntie can at least be relied on to accept. (I have even seen, indeed contributed to, a multi-author volume in which the editors dedicated their collection of other men's flowers to their wife.) The most embarrassing of undesired and undesirable favours is the *Festschrift*. Some years ago an aging and eminent physicist, sensible of the approaching danger, declared in an article with the title of "Fest me no Schriften" that he did not wish to become a pretext for the unloading of unrefereed and possibly otherwise unpublishable contributions by his former students and colleagues (whom he probably did not like anyway). The Duke of Wellington once declined a dedication, explaining that he had been obliged to make a rule to do so "because, in his situation as Chancellor of the University of Oxford, he had been much exposed to authors".

As to the foreword, its object is to praise the book, and a hypocritical show of modesty can be avoided if the services of an elder of the subject can be secured. The leaden phrases that fall so easily from the pens of such illuminati are all too familiar. An ingenious ploy was contrived by Newton, who when President of the Royal Society set up a hand-picked committee to prepare a report on the rival claims of Leibniz and himself to the calculus, and then himself wrote an anonymous and fulsome foreword, commending the conclusions. But let us end with a more wholesome example, that of Boswell, who had no need of specious humility in launching his *Life of Johnson*. In what he candidly termed the "Advertisement" to the first edition, he begins: "I at last deliver to the world a work which I have long promised" and concludes, "nor will I suppress my satisfaction in the consciousness, that by recording so considerable a portion of the wisdom and wit of 'the brightest ornament of the eighteenth century', I have largely provided for the instruction and entertainment of mankind". But then his subject was better than the oxides and oxyacids of sulphur.

A pilgrim's progress

W.F. Bynum

The Correspondence of Charles Darwin, Vol.1 1821-1836.
Edited by Frederick Burkhardt and Sydney Smith.
Cambridge University Press: 1985. Pp.702. £30, $37.50.
A Calendar of the Correspondence of Charles Darwin, 1821-1882.
Edited by Frederick Burkhardt and Sydney Smith.
Garland: 1985. Pp.690. $100, £80.
Darwin Pedigrees. By R.B. Freeman.
R.B. Freeman, University College London: 1984. Pp.84. £8.



IN THESE contracting times, there is comfort in the appearance of the first volume of a set which, the publishers tell us, will take a score of volumes and most of the rest of the century to complete. The project to locate, edit and publish the complete correspondence of Charles Darwin has already been underway for a decade, supported by large grants from several American funding bodies, including the National Science Foundation, the National Endowment for the Humanities and the Andrew W. Mellon Foundation, and overseen by both British and American advisory committees. The editorial team has already involved more than 20 scholars, designated by a hierarchical variety of titles: editors, associate editors, assistant editors, research associates, research assistants and managing editor. The team has a decided Anglo-American flavour, neatly encapsulated by the two senior editors: Frederick Burkhardt, the American scholar who has masterminded the whole project, and Sydney Smith, the Cambridge zoology don who has done so much over the years to secure the magnificent Darwin archives for the Cambridge University Library. The Darwin family has always been exceptionally cooperative and generous in their dealings with Charles Darwin's Alma Mater, and it is pleasing to see the family represented on the British advisory committee through Darwin's grand-daughter, Lady Nora Barlow.

The Correspondence of Charles Darwin, then, has been, and will be, expensive to produce. Will it be worth it? After all, Francis Darwin included a number of the more important letters in his three-volume biography of his father (1887), which he followed up by *More Letters of Charles Darwin* (two volumes, 1903). Charles Darwin's daughter Henrietta Litchfield edited additional ones in her *Emma Darwin: A Century of Family Letters* (two volumes, 1905), Nora Barlow has given us the Darwin-Henslow correspondence (1967) and other scholars have published additional bits and pieces. With about 2,800 letters to and from Darwin already in print, is this present project worth the time and money? The answer is short and unqualified: yes. In the first place, 2,800 letters represent but a fraction of the 13,925 the group has already identified and calendared, and many more will undoubtedly surface.

A Calendar of the Correspondence of Charles Darwin, 1821-1882 gives us a foretaste of the pleasures in store during the coming years and will immediately prove a useful reference tool to historians working on many aspects of nineteenth-century science. The letters are listed and described, and their contents briefly summarized. They come from more than 200 institutions and private collections, and a biographical register lists over 4,000 correspondents and individuals mentioned in the series. Because Darwin lived for so many years in the relative isolation of Down House, he was probably more dependent on the postal service than any other great scientist. The output is staggering: more than 500 letters survive for 1862, almost 600 for 1874 and even in 1881, with his health visibly failing, the surviving correspondence tops 600 items. The last letter listed in the *Calendar* was written two days before he died.

Darwin, however, was not simply an ardent cultivator of the epistolary art, he was also a distinguished one. His letters are often filled with memorable phrases and shrewd insights and are a joy to read. In no future volume of the complete correspondence are the delights likely to be greater than those contained in the first. This is partly because the time span is longer, from the first surviving letter, written to the 12-year-old Darwin by Mary Congreve, to a letter of 30 December 1836 from Robert FitzRoy to Darwin, discussing publication plans for the diaries, journals and reports prepared in conjunction with the voyage of the *Beagle*. Sandwiched between are more than 300 letters to and from Darwin, and a sprinkling of letters about or affecting him (such as George Peacock's letter of August 1831 to J.S. Henslow, asking him to recommend a naturalist to accompany FitzRoy). They detail a pilgrim's progress, from a spirited young lad variously called Mr Charles, Bobby and Charley, to a mature naturalist, settled in London to work through the large collections of specimens (zoological, botanical, mineralogical and palaeontological) he had acquired on his five-year voyage around the world. The Darwin that emerges is not radically different from the one which numerous biographers and historians have described, but the assembled correspondence does present an uncluttered vision of his early personality, development, and family and social relationships. Two or three points are worth stressing particularly.

First, from the earliest years of the correspondence, Darwin was investing great quantities of libidinal energy engaging with Nature: partly in hunting and fishing, but also in collecting and studying the objects of the natural world. A long, important and largely previously unpublished series of letters between Darwin and his cousin William Darwin Fox, makes clear that insects were Darwin's first scientific passion: "I am dying by inches, from not having any body to

1. *Mr. Darwin's Seat in Captain's Cabin* 2. *Mr. Darwin's Seat in Poop Cabin with Cot slung behind him*
3. *Mr. Darwin's Chest of Drawers* 4. *Bookcase* 5. *Captain's Skylight*

Side elevation of HMS Beagle, *1832. Doubts about her size (90 feet in length, 242 tons) were a recurring feature of Darwin's letters prior to the voyage; thus (to W.D. Fox): "My objection to the vessel is its smallness.... As to its safety I hope the Admiralty are the best judges".*

talk to about my insects", he wrote in 1828; in 1831, on hearing he was off on the *Beagle*, another collecting friend Frederick Watkins wrote to Darwin, "Woe unto ye Bettles of South America, woe unto all tropical butterflies". Despite Henslow's inspiring Cambridge lectures in botany, and despite Darwin's brief geological tour of Wales with Adam Sedgwick, the Darwin who set out on the *Beagle* was first and foremost an entomologist. He very quickly became much more of a geologist, partly through the influence of Lyell's *Principles of Geology* (three volumes 1830-1833), the first volume of which FitzRoy gave him just before the *Beagle* set sail (the other volumes being sent to him in South America), but mainly through the sheer impressiveness of the geological formations and activity the voyage offered. "There is nothing like geology", he wrote home in 1834; "the pleasure of the first days partridge shooting or the first days hunting cannot be compared to finding a fine group of fossil bones, which tell their story of former times with almost a living tongue."

The Wedgwood connection — Susannah (1765–1817), daughter of Josiah Wedgwood the founder of the pottery dynasty, and Charles Darwin's mother, with her brother (centre).

Darwin's transformation from beetle collector to rounded naturalist is strikingly demonstrated in the volume. Equally significant, however, is the light it sheds on his circle: family, more distant relations and friends. The letters remind us that the sage of Down House was once a carefree young man who lay in the strawberry patches and played Housemaid and Postillion with Fanny Owen. His letters to her are lost, but Fanny's to Charles survive (mostly with strict instructions for him to burn them instantly once he has read them). One wonders what he felt when, barely a year at sea, he received his sister's letter informing him that the girl he described as "la belle Fanny", "the prettiest, plumpest, Charming personage that Shropshire possesses" was engaged to another. Fanny's letters suggest Charles was infinitely better off with Emma Wedgwood, still a shadowy figure in Volume 1. Her time will undoubtedly come in Volume 2.

This lapse into the language of romance is entirely appropriate, for these letters reflect a real world very like the one created by Jane Austen. Darwin's sisters took it in turn to write him each month, and their long and newsy letters are full of the stuff of the social history of upper middle class, provincial England during the 1830s. They send him news of the Reform Bill and the cholera epidemic, but also of engagements and marriages, births and deaths, balls and visits. His sisters despair as the voyage stretches from two to three to five years; and Darwin's own stiff upper lip begins to quiver as seasickness persists, the novelty fades and (after the visit to the Galapagos Islands), the scientific returns decrease exponentially. "In short, I am convinced it is a most ridiculous thing to go round the world, when by staying quietly, the world will go round with you." He penned this prophetic sentiment in the penultimate letter he wrote home, in July 1836.

This volume is teeming with life and exuberance. There is little of the ill health that was to plague Darwin's later years, and, because his correspondents are allowed to speak for themselves, much about his early circle, from his irascible and fascinating brother Erasmus to his quietly supportive father to his wonderfully demonstrative sisters. The letters are finely edited and presented, even if the explanatory editorial apparatus could profitably have been fuller. Several appendices provide additional information for these years, including the main events of his life, a list of books and people on board the *Beagle*, and biographical details of those with whom he corresponded or who are mentioned in the letters. The family connections can now be additionally sorted out with the aid of Richard Freeman's new book, *Darwin Pedigrees*. This reprints the scarce pedigree first produced in 1888 by H.F. Burke, and incorporates Freeman's own researches, particularly on later Darwins and on female members of the family.

For some years now, historians have referred (sometimes disparagingly) to the Darwin Industry. All it needed, it seems, was an injection of foreign capital to show itself alive, well and an immensely fruitful activity. □

Happy repitition

David L. Hull

The Survival of Charles Darwin: A Biography of a Man and an Idea.
By Ronald W. Clark.
Random House/Weidenfeld & Nicolson: 1985. Pp.449. $19.95, £14.95.

BIOGRAPHIES of Charles Darwin have become as stylized and predictable as kabuki theatre — Darwin's comfortable childhood, his lazy days at Cambridge, the happy accident that put him on board the *Beagle*, his return to England after his arduous voyage, his marriage and retreat to Victorian gentility at Down House, his mysterious illness, the long gestation of the *Origin of Species*, Wallace's bolt from the blue, T.H. Huxley taking on "Soapy Sam" at the 1860 meeting of the British Association for the Advancement of Science, the eventual triumph of Darwin's theory, Darwin's later publications, his death and burial at Westminister Abbey. Clark's biography is no exception, although he does strew this familiar narrative with interesting titbits. For example, anyone reading Darwin's *Life and Letters* might notice that Darwin called his residence near the village of Downe in Kent "Down House", instead of "Downe House", and wonder why. Clark explains that the village was "Down" until 1842 when the government added the "e" to distinguish the village in England from the county in Ireland. There was, after all, the continuing Irish Problem. Darwin refused to adopt the new spelling for his own house.

Clark does not stop with Darwin's death in 1882. His book is the biography of a man, but it is also the biography of an idea. He traces the decline of evolutionary theory towards the end of the nineteenth century, its rough treatment at the hands of such Mendelians as William Bateson, the resurgence of Lamarckism, the "Monkey Trial" in Tennessee, the increasing influence of mathematics on the theory and the formation of the Modern Synthesis. He concludes with two chapters, one entitled "Molecular Biology Takes Over" and a second in which he describes recent controversies over the tempo of evolution and over cladistic analysis. These discussions are necessarily somewhat cursory, and some evolutionary biologists might protest that molecular biology has not taken over their field. The most that can be said is that molecular data have been incorporated into traditional views of the evolutionary process. With respect to the pace of evolution, Clark shows that emphasis on slow, gradual evolution has alternated periodically with more saltative views. Eldredge and Gould's punctuational model is but one more swing of the pendulum.

Another theme that recurs in the book is the social responsibility of scientists. Scientists do not publish in a social vacuum. Other experts read their work but so do theologians, reporters, high-school teachers and politicians. For example, the

anonymous reviewer of Darwin's *Descent of Man* (1872) in the London *Times* chastized Darwin for being "reckless" in publishing such "disintegrating speculations" in such perilous times. Fifty years later and an ocean away, Bateson was to be given a similar lesson when he claimed at a meeting of the American Association for the Advancement of Science that the "origin and nature of *species* remains utterly mysterious". As might be expected, newspaper headlines declared triumphantly "Darwinism Disproved".

Another 50 years on the scenario was replayed when critics of sociobiology warned that statements made by E.O. Wilson and company could easily be used by racists and

Bromley Public Libraries

Down House, at Downe in Kent, Darwin's home from 1842 until his death in 1882.

sexists. These criticisms in turn were taken up by Creationists as more proof that evolutionary theory is false. Even more recently, advocates of a new theory of biological classification termed "cladistics" have proclaimed that cladistic classifications are not about evolution but about patterns of character distributions, no matter how thay may have arisen. Rumours of Darwin's death in South Kensington were a result. More recently still, Tom Bethell in *Harper's* has complimented cladists for having a truly scientific outlook. "Only evolutionary agnostics like Patterson and Nelson and other cladists seem willing to live with doubt. And that, surely, is the only truly scientific outlook." As far as Bethell is concerned, the proper attitude towards evolution is the one that Huxley advocated for the existence of God — not proven. On these standards, very little has been proven in science, including relativity theory, quantum theory, not to mention continental drift. The authenticity of the Shroud of Turin is quite another matter. There is no doubting here.

Once again, Creationists are sure to make ample capital out of this intramural dispute among scientists. But what are scientists to do? No matter how judiciously they present their views, no matter how technical the journal, their statements can always be misused by those whose political or religious convictions outweigh considerations of intellectual integrity. If nothing else Clark's history of Darwinism shows that scientific disputes continue, as do marriages and divorces according to Dr Pangloss, in happy repitition. □

Philip Kitcher

The Nature of Selection: Evolutionary Theory in Philosophical Focus.
By Elliott Sober.
MIT Press: 1984. Pp. 383. $33.75, £30.

VIRTUALLY no philosopher is immune to the fear of irrelevance. Despite the reassurance that one is grappling with problems that have challenged the Western intellectual tradition since the time of the Greeks, there is always the quiet voice that asks "Does anyone care?". So it is tempting to announce that philosophy is — and perhaps has always been — the servant of the sciences, and to immerse oneself in the theoretical problems that arise within some more self-confident domain of inquiry. Even this may not put an end to the whispered doubts. If philosophers turn meta-scientists, do they manage to contribute anything that a reflective practitioner could not have achieved more easily? Is philosophy only useful when it tidies the corners that talented scientists are too busy to set in order for themselves?

A long and distinguished tradition in the philosophy of science reveals the impact of combining philosophical understanding with deep knowledge of the sciences. The tradition is strongest in the philosophy of physics, where reflections on space, time, cause and chance have proven valuable both to science and to philosophy. More recently, there has been a fruitful alliance between philosophy and psychology, in which students of cognitive science have looked to philosophers for conceptual guidance, offering in return new perspectives on old problems about mind, language and knowledge. The publication of Elliott Sober's new book shows that biology's turn has now come.

On reading a draft of *The Nature of Selection* in the autumn of 1983, I formed the opinion that it would illuminate both biology and philosophy. That impression is amply confirmed by study of the published version. Sober has focused evolutionary theory for philosophers, and thereby provided new material for inquiry into the general problems of the philosophy of science, the problems of explanation, confirmation and theory structure. He has also addressed a number of major conceptual problems that currently confront practising biologists. In his hands, some disputes about natural selection are reformulated; others are dissolved.

Sober's main project is to understand the causal notions that figure in evolutionary theory. He starts from the conviction that many contemporary debates about the evolutionary process persist because the protagonists have failed to understand the character of the causal claims that they and their opponents are making. The first part of the book is devoted to an analysis of the concepts of selection, adaptation and fitness, and to a delineation of the role that these concepts — as well as the concept of chance — play in evolutionary theory. The second part develops the analysis in the context of a dispute to which Sober has made substantial contributions, the controversy about units of selection. Substantial though that previous work was, the present discussion supersedes it.

On Sober's account, evolutionary theory is best construed as a theory of forces. Evolution is a process in which typically (though not invariably) gene frequencies change along a lineage, and evolutionary theory attempts to specify the forces that produce the changes. An immediate consequence of this perspective is that the old problem about the evolutionary tautology is broached and quickly disposed of. (Those who are tempted to use the term "tautology" in discussions of evolution ought to be required to read Sober's second chapter.) A more important result is the distinction between selection *of* and selection *for*. Selection of *objects* contrasts with selection for *properties*. The distinction can be made by considering the electorate of the United States. American voters appear to select candidates who are bereft of foresight and understanding. Yet there is no selection for lack of foresight. The property selected for is surely telegenicity.

Although there are several other discussions in the first part of the book that will interest scientific readers, it is probable that they will think of the second part as where the action is. Sober's approach to the problem of units of selection starts with a chapter, allegedly designed to alienate all parties to the controversy, in which he tries to uncover confusions and fallacies in all the major positions. He continues with an analysis that makes explicit appeal to the concept of cause: a necessary condition for X-selection (group selection, genic selection, species selection and so forth) is that there should be some property of Xs that is a positive causal factor on the survival and reproduction of organisms. (Sober eventually generalizes, allowing for entities other than organisms to serve as "benchmarks" of selection.)

However, the concept of cause cannot be

● The Royal Historical Society has published a collection of correspondence to complement Jack Morrell and Arnold Thackray's *Gentlemen of Science: Early Years of the British Association for the Advancement of Science* (published in 1981 by Oxford University Press and reviewed in *Nature* **294**, 19; 1981).

In *Gentlemen of Science: Early Correspondence* Morrell and Thackray have gathered together "what [they] judge to be the 294 letters of greatest significance to the student of early Victorian science and culture", focusing upon letters written by and to William Vernon Harcourt, a pivotal figure in scientific matters during the early and middle nineteenth century.

Oxford University Press

NEW AND FORTHCOMING

The Physical Basis of Organic Chemistry

Howard Maskill

A rigorous but not over-mathematical account of the physical properties of modern organic chemistry, containing many worked examples and end-of-chapter problems.

0 19 855192 4, £30, 480 pp., illus., June 1985
0 19 855199 1, £14.95 (Paperback)

Engineering Rheology

Roger I. Tanner

This book is based on kinematics, and includes computer methods, thermal effects, stability and turbulence, and applications to lubrication, calendaring, spinning and extrusion

0 19 856144 X, approx. £50, 464 pp., illus., Clarendon Press, June 1985

Thermodynamics of Fluid Systems

L. C. Woods NEW IN PAPERBACK

'superb . . . No one concerned with thermodynamics . . . can afford to be without this book' **Journal of Fluid Mechanics** (from reviews of the hardback)

0 19 856180 6, approx. £12.50, 372 pp., Clarendon Press, June 1985
Oxford Engineering Science Series 2

Basics of Communications and Coding

William G. Chambers

A concise yet wide-ranging introduction to communications theory, covering both traditional material and modern topics not usually included at this level.

0 19 853195 8, £25, 256 pp., Clarendon Press, May 1985
0 19 853194 X, £12.50 (Paperback)

Turbulence and Diffusion in Stable Environments

Edited by J. C. R. Hunt

Discusses theoretical, computational, and experimental research aiming to improve understanding and methods of quantitative modelling of turbulence and diffusion in stratified flows.

0 19 853604 6, approx. £28, 300 pp., Clarendon Press, June 1985
Institute of Mathematics and its Applications Conference Series New Series 4

Boolean-valued Models and Independence Proofs in Set Theory NEW EDITION

Second edition

J. L. Bell

'. . . a very useful introduction to the subject.' **Mathematical Reviews** (on the first edition)

This expanded second edition provides a motivated account of the central independence results in set theory using the method of Boolean-valued models. Many exercises are included.

0 19 853241 5, £16, 192 pp., Clarendon Press, June 1985
Oxford Logic Guides 12

Risk

Man-made hazards to man

Edited by M. G. Cooper

This accessible book examines the growing subject of 'risk management' from the different viewpoints of a number of distinguished scientists and applied scientists.

0 19 854154 6, £15, 160 pp., Clarendon Press, May 1985
0 19 854155 4, £9.95 (Paperback)

Animal Intelligence

Edited by L. Weiskrantz

Reviews the current state of knowledge in this subject area, looking at new insights into animals' capacities, and highlighting those issues which are still controversial.

0 19 852124 3, £32.50, 216 pp., illus., Clarendon Press
Oxford Psychology Series 7

Insects in Camera

Christopher O'Toole, with photographs by Ken Preston-Mafham

This book—with its novel format, nearly 300 magnificent colour photographs taken live in the field, and very readable essays and captions—provides an all round, up-to-date approach to insect behaviour for both the layman and the specialist.

0 19 217694 3, £14.95, 168 pp., 287 colour plates (in 64 double page spreads)

Immigrant Killers

Introduced predators and conservation of birds in New Zealand

Carolyn King

This book deals with one of the world's best known conservation horror stories—it surveys the 1000 year history of introduced predators to New Zealand, and tackles the difficult problem of protection of the remaining bird fauna.

0 19 558115 6, £29.50, 244 pp., illus., May 1985
OUP Auckland

Natural Inorganic Hydrochemistry in Relation to Groundwater

An introduction

J. W. Lloyd and J. A. Heathcote

Sets out to provide a comprehensive but simple account of groundwater chemistry—a subject of growing importance—with engineers and hydrogeologists especially in mind.

0 19 854422 7, £32.50, 304 pp., illus., Clarendon Press, June 1985

An Atlas of Hyperstereograms of the Four-dimensional Crystal Classes

E. J. W. Whittaker

Aims to clarify the nature of the symmetry operations, crystal families, crystal systems, and geometrical crystal classes of the four dimensions, making use of hyperstereographic projection.

0 19 854432 4, £32.50, 216 pp., illus., Clarendon Press, May 1985

LAND-USE AND PREHISTORY IN SOUTH-EAST SPAIN

A. Gilman, *California State University* and **J.B. Thornes,** *Bedford-Royal Holloway College, London*

This book is based on a major research programme which has aimed to provide an economic foundation for reinterpreting the Neolithic-Bronze Age sequence of South-East Spain in terms of emergent social complexity. This is an innovative combination of archaeological, historical-geographical and geomorphological evidence, and is the first book to offer a coherent evolutionary model for the archaeological sequence of the region's prehistory.

THE FIGHT FOR FOOD

factors influencing agricultural production
Harold E. Croxall and **Lionel P. Smith**

This book presents a clear picture of the factors governing agricultural productivity, including weather, soil, biology and ecology, and human, social, economic and political factors. The authors discuss the complex interactions that produce the wide variety of changing situations in which farmers must operate.

1984 234 pp Hardback £15.00/$25.00 Paperback £4.95/$7.95

CHROMOSOMES TODAY: VOLUME VIII

Edited by M.D. Bennett, *Plant Breeding Institute, Cambridge* **A. Gropp** *Medizinische Hochschule, Lübeck* and **U. Wolf** *Universität Freiberg, i. Br.*

The proceedings of the 8th International Chromosome Conference, held in Lubeck, West Germany in September 1983. These conferences are the premier forum for the presentation of research and review papers in both plant and animal (including human) chromosome-related research. This volume therefore offers the hard-pressed biologist ready access to these fast-moving fields.

1984 400 pp Illustrated Hardback £30.00/$50.00

LIPIDS IN PLANTS AND MICROBES

J.L. Harwood and **J.N. Russell,** *University College, Cardiff*

A concise but wide-ranging comparative review of the structure, metabolism and functions of lipids in plants and microbes. Their differences from animal lipids are clearly brought out and with the increasing importance of microbes and plant cell cultures in the food industry, biotechnology and medicine, the book is timely.

1984 169 pp 64 line illustrations Hardback £19.50/$29.50 Paperback £7.95/$12.50

CLASS EXPERIMENTS IN PLANT PHYSIOLOGY

Hans Meidner, *University of Stirling*

This book presents detailed protocols for over 100 class experiments in plant physiology. Some 40 university teachers have contributed their best tried and trusted class experiments, each of which has again been minutely tested by Professor Meidner who has then rewritten and edited them into a uniform style. The result is a source book of unrivalled authority and reliability.

QUATERNARY PALEOCLIMATOLOGY
methods of paleoclimatic reconstruction
R.S. Bradley, *University of Massachusetts, Amherst*

The paleoclimatology of the Quaternary is of widespread interdisciplinary interest. This comprehensive volume provides an authoritative and unified introduction to the methods used to reconstruct past climates. Climatologists, paleoecologists, palynologists, oceanographers, glaciologists, geomorphologists, geologists and archaeologists will all find the book highly relevant to their needs in building up pictures of former climatic conditions.

HEMISPHERICAL PROJECTION METHODS IN ROCK MECHANICS
S.D. Priest, *Imperial College, London*

Hemispherical (or 'stereographic') projection methods have many applications in rock mechanics. The aim of this book is to explain in simple terms methods that allow the plotting and analysis of the structural features that control the behaviour of jointed rock masses. It is designed to take the reader in easy stages from an elementary level to a comprehensive understanding of relatively advanced new methods. The treatment relies firmly on worked examples, exercises and many diagrams; only elementary mathematics and an ability to visualise structures in three dimensions are assumed as background.

March 1985 144 pp 89 line illustrations Paperback £8.95/$14.95

ROCK MECHANICS
for underground mining
B.H.G. Brady, *University of Minnesota,* and **E.T. Brown,** *Imperial College, London*

Rock mechanics is now established as a key field of interest to many engineers and earth scientists, and is central to work in mining and geological engineering. Indeed, rock mechanics can now justly be regarded as the basic mining science, and this book should help to improve its integration with other mining subjects. Its purpose is to present the subject in a manner that will show how it can be used in mining method selection and mine design. Based on extensive professional, research and teaching experience, this book will provide an authoritative and comprehensive source of reference.

May 1985 550 pp 351 line and 7 tone illustrations Hardback £40.00/$60.00 Paperback £15.95/$29.95

GEOMORPHOLOGICAL HAZARDS IN LOS ANGELES
R.U. Cooke, *University College London*

Bringing together for the first time a wide range of information derived from field observations, interviews, manuscript records, local agency reports and published sources, this book presents a unique analysis of the ways in which a rapidly developing metropolis has come to terms with complex geomorphological hazards. As the Los Angeles experience in managing such problems is probably more advanced than in most democratic urban communities elsewhere, it should provide useful insights for other urban communities.

CHAPMAN AND HALL

Chemistry Sourcebooks

Bench-top reference volumes specifically tailored to the everyday requirements of individual researchers.

Derived from the Dictionary of Organometallic Compounds, these ten Sourcebooks provide easy access to the key data on the most important and most useful organometallic compounds.

Each Sourcebook contains compounds divided according to metal element: thus allowing individual researchers to carry the data relevant to their own specialization within just one or two volumes.

Every Sourcebook has:-

- ☐ clear and concise dictionary format
- ☐ comprehensive and complete indexing
- ☐ an additional structure index
- ☐ data on over 1000 organometallic compounds
- ☐ information derived from the acclaimed DOMC
- ☐ attractive bench/desk top presentation
- ☐ excellent value – you need only buy the information of direct reference to your research interests

Each Sourcebook is of similar structure:- Preface; Introduction; Structure index; Entries in molecular formula index; Molecular formula index; CAS registry number; Index.

The Sourcebooks are paperbacks 276 × 210 mm in size, and are to be published in May 1985.

For a FREE full colour brochure, please write to:-
The Promotion Department, Chapman and Hall, 11 New Fetter Lane, London EC4P 4EE.

Reader Service No.31

taken for granted, and Sober invokes the philosophical literature on probabilistic causation to provide a more detailed analysis. His final suggestion is that C is a positive causal factor in the production of E in a population, if, for things in the population, the occurrence of C does not lower the probability of occurrence of E on any background of causally relevant conditions, and raises it on the background of at least one causally relevant background condition. (Roughly: smoking is a positive causal factor in the production of heart attacks if, whatever constellation of traits an individual has, smoking would make that person more prone to have a heart attack.) Sober is aware of the limitations of this analysis, which he forthrightly describes as "circular" (p.291). It would be more appropriate to treat the proposal as a recursion clause for extending our ability to identify positive causal factors. For it is this extended ability that we need to tackle the controversies about units of selection. I shall postpone the question of whether the "circularity" is bothersome.

The last chapter brings the philosophical account of causation to bear on four debates about levels of selection. Sober offers analysis of Dawkins's celebrated rowing analogy, and a diagnosis of why we should not be rushed into thinking that the gene is the one and only unit of selection. However, Sober is careful to point out that his arguments help us understand the idea of "selfish DNA" (developed by Doolittle, Sapienza and others). He also attempts to provide conceptual underpinnings for the claims about macroevolution and "species selection" that have been advanced by Stanley, Gould, Eldredge and Vrba. Here, too, is a discussion of Hamilton's ideas about inclusive fitness and local mate competition, and an extended exploration of proposals about group selection.

The account of inclusive fitness seems to me to be the least useful part of this chapter. Sober starts by suggesting that Hamilton "consolidated an insight that had been available within population genetics for some time" (p.336). Quickly adding that he does not mean that Hamilton underwrote Haldane's apocryphal quips about sacrificing himself for two brothers or eight cousins, Sober continues by reminding us that the fitness of a trait is standardly defined as the average fitness of the bearers. So Hamilton's insight can be reduced to a rather elementary idea: "There are many ways for a gene to be advantageous *on average*" (p.336).

This evaluation strikes me as parallel to the view that Darwin consolidated an insight of Malthus. Hamilton does not seem primarily interested in identifying the fitnesses of individual alleles or of allelic pairs. (That approach was later adopted by Dawkins, and is the target of much of Sober's criticism.) Inclusive fitness was introduced because of the apparent inadequacy of the classical notion of fitness for *phenotypic* traits, an inadequacy that is most obvious in traits that reduce the expected reproductive success of their bearers. When we average over the set of individuals with any such phenotype we are likely to find that the (classical) fitness lies below the mean for the population. For the lucky recipients, the kin whose reproductive success is boosted by the fact that others have the phenotypic trait in question, *are not themselves bearers of the trait*. They only enter into the set over which it is appropriate to average when we compute the chances for spreading the gene(s) that underlie the phenotypic trait, and thus calculate — as Haldane did in rough-and-ready fashion, and as Hamilton did systematically — the way in which reduced genetic representation through descendants is offset by increased genetic representation through kin.

In general, I find Sober's discussion of inclusive fitness confusing because his use of "altruist" can cover both individuals who bear genes that might (in the right circumstances or in the right combination) dispose them to sacrifice their own reproductive interests to those of others, and individuals who actually do make these sacrifices. The treatment of group selection is another story. Sober's analysis of this tricky notion is one of the high points of the book.

The distinction between group and individual selection is introduced with an apt example. We are to imagine a set of internally homogeneous populations with different average heights. We observe that tall individuals are reproductively more successful than short ones. We note also that groups of taller individuals leave more descendants than groups of shorter individuals. How do we tell if we have a case of individual selection or a case of group selection?

Everything turns on whether the causally relevant factor is the property of being tall or of being in a group with a large average height. To recognize the difference, we shall need to consider a larger ensemble of populations, asking how short individuals would have fared if they had found themselves in tall groups, and so forth. The probabilistic treatment of causality allows the conditions to be stated precisely.

Sober's work will have been done if the controversies about group selection can now be resolved by appeal to the empirical evidence. There is one obvious possible snag. The probabilistic conditions bear reference to causally relevant background conditions. If reductionists and anti-reductionists disagree on the properties that can be invoked as genuine causally relevant background conditions, then Sober's analytic apparatus may fail to bring resolution. Faced with a putative case of group selection, the reductionists produce what they are happy to count as a causally relevant property of individuals, given which the group characteristic makes no difference to the probability of survival and reproduction. If their opponents contend that the alleged property is contrived, an artefact rather than a genuine cause, then Sober's analysis will have to be extended by explicating the notion of a causally relevant background condition. So we cannot tell in advance if all the conceptual work has been done. But even pessimists should be confident that Sober has taken us a long way forward.

The Nature of Selection is not merely a book that clarifies dramatically some vexed issues. It also points to new questions and, perhaps, to refinements of causal notions that it introduces. In its achievement and in its open-endedness it deserves comparison with the work that Sober singles out as having started his own train of thought. George Williams's *Adaptation and Natural Selection* has been important to philosophers as well as to biologists for its combination of biological insight and philosophical acumen. Sober's is the answering philosophical voice, the voice of a first-rate philosopher and a knowledgeable student of contemporary evolutionary theory. His book, like Williams's, merits broad attention among both communities. It should also inspire others to continue the conversation. □

Philip Kitcher is Professor of Philosophy at the University of Minnesota. His latest book, Vaulting Ambition: Sociobiology and the Quest for Human Nature, *will be published in September.*

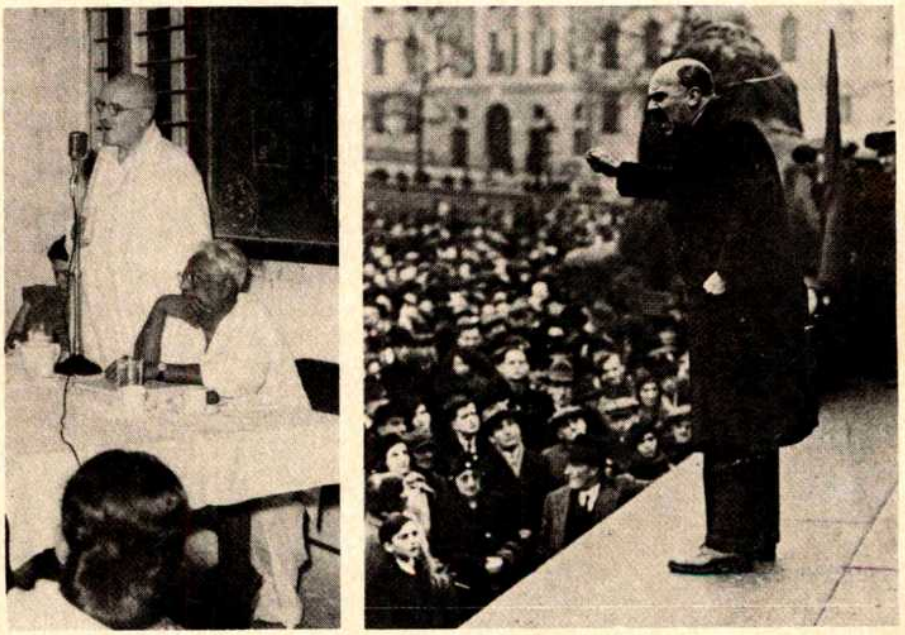
Larger than life

R.C. Lewontin



On Being the Right Size and Other Essays.
By J.B.S. Haldane. Edited by John Maynard Smith.
Oxford University Press: 1985. Pp. 187. Pbk £4.95, $6.95.

I MUST confess that when I first met J.B.S Haldane I thought him a bit of a humbug. Dressed in his *dhoti*, smoking a twisted black Burmese cigar and addressing a group of admirers in a Dutch café, he seemed unreal. Nor was I alone in that opinion. Once in an American department store where we had gone to buy some things for Helen Spurway, Haldane pulled out an Indian rupee note, announcing to the sales clerk "I'm a Hindu, you know". As he left, she turned to me and said "That's funny. I could have sworn he was one of those high-class Englishmen".

But, of course, Haldane was vastly more than a showman. He was the most incisive and wide-ranging intellect I have ever known, original, iconoclastic, a master at making connections between apparently unrelated phenomena, and by far the best popular science writer who has ever addressed an English-speaking readership. All these aspects are displayed in this collection of his essays, chosen with great judgement by his former student and colleague John Maynard Smith, essays ranging from the origin of life and the gods, to the Last Judgement, somewhere around the year 36,000,000. In between Haldane explains in plain English what "hot" means, how the organism is produced by interaction of its genes and its developmental environment, why one can survive for hours shut up in an air-tight box and how capitalism has made a commodity out of health. Written as clearly as they are, these essays tempt the reader to take them all at one sitting, but I advise against it. The best prescription is one a day followed by deep thought.

Haldane the humbug shows up occasionally, as when he quotes extensively from the Norse epic *Volospa* in the original, a bit of flummery that can only be meant to give an impression of fluency in an esoteric language. Yet it seems so unnecessary. Haldane was a person of genuinely wide learning, as shown, for example, in the essay "Is History a Fraud", where a variety of historical detail is displayed in the service of a central idea: the superiority of the practical over the merely intellectual. It is a sign of the contradiction that marked Haldane's world view that he could prefer Pasteur above Darwin because the former solved a "practical problem of living", yet at another time could praise an idea as "interesting, even if not true".

Haldane the critical scientist comes out best in "The Biology of Inequality" which shows a subtlety of understanding of the relationship between gene, environment and organism that is, even today, absent from the thinking of most biologists. Yet here again is a contradiction. Haldane makes clear in this essay that it is not the phenotype, but the pattern of reaction to a contingent environment that is inherited. Yet earlier, in "The Future of Biology", he writes of "the main gene that determined his father's mathematical powers". Nor was it simply wisdom acquired in the ten years between these essays. To the end of his life, Haldane remained committed to a hereditarianism in regard to human psychic development, a biological determinism that may seem strange in

Public faces — Haldane addressing a "United Front" meeting in Trafalgar Square, 1937 (right), and at the Indian Statistical Institute, Calcutta. The pictures are reproduced from J.B.S., *Ronald Clark's biography which was re-issued in paperback last year by Oxford University Press.*

someone who claimed to be a revolutionary socialist. The key to this apparent paradox can be found in what appears to be Haldane's preoccupation with religion.

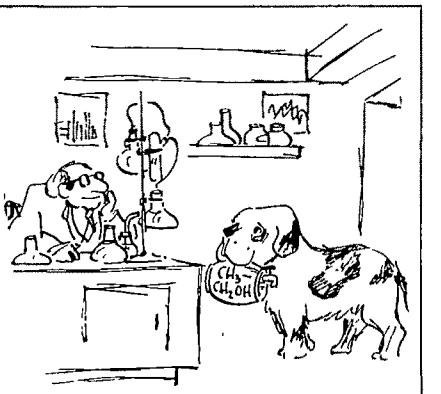
In essay after essay in this collection Haldane returns to the subject of religion. It is not simply that the editor has chosen essays on religious subjects, such as "When I am Dead", "God-makers" and "Science and Theology as Art Forms". Haldane brings in Christianity, Hinduism, religious myth in general and an Egyptian fakir in particular as integral to the points he is making about history and science. To understand why this is so, we must realize that Haldane was born in the last years of Victoria's reign and his intellect was formed in the Edwardian period. The primary intellectual struggle in his view, a view shared by Marxists of the 1930s, was the struggle between materialism and philosophical idealism. Marxism for Haldane, as for H.J. Muller, meant the fight to overturn the superstition, both scientific and social, that marked nineteenth century ideology, and its replacement by a materialist, scientific society. Part of that materialism was a belief that biological technology including eugenic measures could be instrumental in putting society on a better basis. The view seems naive to us now. If biology is to be relevant to reorganizing society, it must be the biology of what is in our heads, not what is in our gonads. Nevertheless, we must side with Haldane's desire to replace mystifying social myths by rational realities. □

R. C. Lewontin is a Professor of Biology in the Museum of Comparative Zoology, Harvard University.

Schools of thought

Struther Arnott

Graduate Research: A Guide for Students in the Sciences.
By Robert V. Smith.
ISI Press, 3501 Market Street, Philadelphia: 1984. Pp.182. Hbk $21.95 (North America), $24.95 (elsewhere); pbk $14.95 (North America), $17.95 (elsewhere).



HERE is a programme instructing the ambitious mediocracy how to apprentice themselves to the trade of being a (US) scientific worker. It begins at the same inspirational level as it continues with the thought that "it is crucial for graduate students in the sciences to master this skill [in research] *because their advanced degrees depend upon it*". It concludes with the optimistic and self-congratulatory assurance that "you should expect to find a good position".

This is a "how to" manual with a vengeance: how to get started; how to choose a research field and a mentor; how to manage time and libraries; how to write dissertations and papers; how to get grant support and a job; even how to note rather than to take cognizance of and how to prepare a consent form for research on human subjects. Thank goodness the chapters on ethics and creativity are not "how to" ones. But there we are regaled with a re-run of Kekulé's reverie which produced the structure of benzene. Inexplicably absent is the crucial part of the dream where some of the dancing chains of atoms joined ends to form rings. Such persistence in missing the point is a general characteristic of this book.

There is a tidy-minded part of me which was impressed by Dr Smith's thoroughness in mustering many useful thoughts about our graduate schools. I and my colleagues surely would want our doctoral students, potential and actual, to be aware of the management structures in our (usually very large) universities, to be familiar with the various opportunities for financial support, and to be chary of over-involvement in teaching and in passive attendance at courses and seminars. However, not all the wise saws and modern instances are as pleasing. Few of us would dispute that "excessive television is a deterrent to purposeful observation" but would any of us want to be saddled with protégés needing such banal advice or with disciples who would formulate the hypothesis that "sensory deprivation in human subjects is associated with increased alienation and manifested as loneliness" only after a survey comparing deaf and blind widows with widows having normal hearing and sight?

The author does assert at one point that "research... requires certain personal traits and practices. Some characteristics must already be part of the individual, some can be improved with practice". I agree completely. What strains my credulity is the implication that a beginning graduate student typically could have postponed until reading this book the acquisition and development of the traits of a successful scholar or researcher. Yet expectation of perpetual opportunity for educational rehabilitation has been a pervasive ingredient of public policy in the United States for at least a generation. Only recently has there been general recognition of the consequences, such as high schools staffed with inadequately rewarded — and therefore indifferent or demoralized teachers — graduating, not very discriminatingly, 75 per cent of their entering classes. Better paid college professors can thereafter, much more expensively, try to remedy ingrained habits of intellectual indolence. Professors condemned to be ushers do not resist this marketplace philosophy nor strive to maintain system in national educational arrangements. The result is loss of rigour, in secondary and in higher education, and buffeting of both by fads and fashions. My own institution recently suffered from a neap tide of interest in computer science which briefly was the proclaimed major subject of more than half the freshman class in our School of Science. Today, that tide is receding, exposing a floundering population dismayed by its lack of quantitative training, analytical skills and capacity for sustained hard work.

A committee of the American Association of Colleges now has demanded baccalaureate programmes which would ensure that their alumni would reason well, would read, write and speak with distinction,

Reproduced from Science Goes to the Dogs, *a new collection of cartoons by Sidney Harris published by ISI Press. Price of the book is $7.95.*

would understand numerical data and the scientific method, and would have historical consciousness and knowledge of the language of the fine arts. Graduate schools, anxious for distinction, will demand at least this, as well as evidence of ability to study in depth which, as the AAC report describes, requires sequential learning, building on blocks of knowledge that lead to more sophisticated understanding and encourage leaps of the imagination and efforts at synthesis.

Now indeed may be the time for us to attend to the quality and configuration of our graduate schools. The main places of employment for holders of the PhD degree are colleges and universities. Population trends will ensure a 15 per cent fall in the traditional university student population by 1995. Scepticism about the value of some academic qualifications could accelerate this decline substantially. A shift in public policy towards investment in earlier stages of education could make the descent precipitous. Even without a revolution in public policy, there may be less than 100,000 academic positions to be filled in the next decade. Success will fall to those graduate schools which order their requirements and incentives so as to be able to recruit more discriminatingly. In such an environment, Dr Smith's book would be useful only to foreigners curious about some of the minutiae of the academic research environment in the United States.

Angles on knowledge

David Miller

The Limits of Science.
By Nicholas Rescher.
University of California Press: 1985. Pp.225. $34.50, £31.50.

THE question of whether there are any limits to empirical science is one that, since Kant anyway, has never been far from the centre of the theory of human knowledge. Logical positivists persuaded themselves (and others) that meaningful investigation is restricted to the results of observation, experiment and induction. Less extreme sufferers from scientism have held that there is no knowledge but scientific knowledge. On the other side it has been suggested that the traditionally conceived method of science as one of "rational triangulation from the empirical data" (as Rescher describes it on p.198) sets more of an external limit to science than an internal one.

In this work, much of which is collated from his innumerable previous books, Rescher approaches the issue from a number of angles: whether there are topics wholly beyond the mandate of science ("no" in Chapter 7, "yes" in Chapter 12); whether science could be perfected, even in principle ("no" in Chapter 9); whether there are problems within its domain that science is in principle unable to answer ("no" in Chapters 4 and 8); whether there are significant questions that for practical (technological) reasons science cannot handle ("yes" in Chapter 10); whether science progresses steadily towards theoretical perfection ("no" in Chapter 5); whether it progresses at an instrumental level ("yes" in Chapter 6); whether extraterrestrial science might be scientifically more advanced than ours (question dismissed in Chapter 11).

The discussion throughout is thoroughly unsatisfactory: superficial, confused, philosophically unsophisticated, repetitive, neologistic, above all deeply antipathetic to theoretical speculation. For example, in the account in Chapter 11 of how our science and alien science might be related, a discussion whose only real conclusion is that there is nothing of interest to say, we read:

> A tiny creature living its brief life span within a maple leaf could never recognize that such leaves are deciduous . Science is limited to the confines of discernibility: as Kant maintained, the limits of our experience set limits to our science [p.197].

So much for the power of ideas. Yet in Chapter 8 Rescher seems properly to appreciate that science is not confined to what we can experience but a method of going wildly beyond it. In a similarly glum mood Rescher seems to suppose that because other planets might be physically very different from ours, scientists there might use

> mathematics very unlike ours . their 'geometry' could be something rather strange, largely topological, say, and geared to flexible structures rather than fixed sizes or shapes [p.177]

Just like some of our mathematics by the sound of it.

Can current science tell us anything about future science, about extraterrestrial science, about possible limits to scientific inquiry? The answer seems obviously that it might be able to, but that what it tells us might be wrong. Rescher persistently muddies this issue, gliding from the platitude that "no adequate justification can be found for the view that science has barriers" (p.130) to the assertion that it has no barriers. He seems not to have appreciated that if "present science cannot speak for future science , [if] there can be no basis for claims of inherent unanswerability" (p.129), then present science cannot speak for present science either, and there can be no basis for its assertions about the natural world. Yet Rescher is unwavering in his belief that the results of science can be justified. We are told that the advance of science amounts to obtaining "a firmer warrant for our claims", not "more of the truth"; and we are warned of the "fallacy . that moves from a picture-of-nature's being a *better-warranted picture* to its being a *better picture*" (pp.73-74). Only someone who confuses justification with truth, and thinks that all moves have to be justified, could see this move as a fallacy rather than as an attempt to discover the truth.

The question of the existence of insolubilia is itself eventually resolved in Chapter 8 as follows:

> How could we possibly establish that a question *Q* will continue to be *raisable and unanswerable* in every future state of science . ? [If we] argue that the answer to *Q* lies 'in principle' beyond the reach of science, it is difficult to see how we could maintain it to be an authentic scientific question [p.128].

In other words, science has no limits except where it has limits.

Most of the topics treated in this book are treated more than once, as though the different chapters had originated from different authors. The writing is always verbose, and horrible hyphenated words ("issue-killer" on p.17, "question-disallowing" on p.22, "hole-internal" on p.131, for example) abound. On p.52 the same 130-word quotation appears twice: in the text and in a footnote appended to it. The word-processor has a good deal to answer for. In most other respects the book is well produced. □

David Miller is Senior Lecturer in Philosophy at the University of Warwick

• P.B. Medawar's *The Limits of Science*, first published in the United States by Harper & Row, and recently in Britain by Oxford University Press, was reviewed in *Nature* **312**, 203 (1984).

Word and number meta-magic

David E.H. Jones

Metamagical Themas: Questing for the Essence of Mind and Pattern.
By Douglas R. Hofstadter.
Basic Books: 1985. Pp.852. $24.95. To be published in Britain later this year by Viking.

DOUGLAS Hofstadter is widely and justly celebrated for his book *Godel, Escher, Bach*, and for his co-production with Daniel Dennett of *The Mind's I*. Between June 1981 and September 1983 he succeeded Martin Gardner in running *Scientific American's* "Mathematical Games" department. He gave his contributions the anagrammatical title of "Metamagical Themas". All 26 of these essays are reprinted in this book. Each now has a postscript of subsequent reflections and developments; in addition there are seven new, specially-written "Themas".

Hofstadter claims that his Themas form a scatter of random dots around his intellectual "home territory", which is concerned largely with thinking, thinking about thinking, and thinking about language. There are Themas on self-referring and self-replicating sentences, and ones on the search for consistent patterns and styles in music and in geometrical artforms. Hofstadter's own research into artificial-intelligence programming is reflected in several Themas, such as those on the pattern-recognition of sameness underlying difference, in particular the recognizable sameness of letters of the alphabet throughout unimaginably many variations of form and fount.

Other Themas continue the tradition of "Mathematical Games", dealing with such topics as Rubik's cube, the mathematics of chaos, computer languages, psychological games with numbers, and logical dilemmas and paradoxes. A rather special cluster of Themas locates a societal region in Hofstadter's territory: his concern over mass gullibility, innumeracy and some political issues. Each Thema is complete in its own right, but most are buttressed and extended by others elsewhere in the book. It's a format ideal for browsing; rather like his previous books, in fact. There is an excellent bibliography, with short notes on the works cited.

To illustrate Hofstadter's style and matter, I'll outline one Thema in greater detail, No.23 "On the Seeming Paradox of Mechanizing Creativity". Could a computer be creative in the human sense? Or must it always be, in effect, a huge fast-scanned dictionary of clichés? After considering the background to this question, Hofstadter introduces an example of

Wiley

LOWER PALAEOZOIC OF NORTHWESTERN AND WEST-CENTRAL AFRICA

edited by **C.H. Holland,** *Department of Geology, Trinity College, Dublin*

Provides the first compilation in the English language of the stratigraphy, palaeontology, sedimentology, palaeogeography, and palaeoclimatology of the Lower Palaeozoic found in northwestern and west-central Africa. Geological formations discussed include the Lower Cambrian trilobite-bearing sequences of Morocco, those showing evidence of late-Ordovician glaciation in west-central Africa, and the Silurian-Devonian sequences of Morocco and Algeria. Much of the vast area of difficult country covered is desert or mountain and very sparsely populated, making the area poorly documented. Most of the material has been gathered from scattered sources, much of it only available in French, making this a very valuable reference source.

Series: Lower Palaeozoic Rocks of the World, Volume 4

0471 10357 8 554pp February'85 £69.00

IMPOUNDED RIVERS

by **G.E. Petts,** *University of Technology, Loughborough*

Presents a comprehensive geographical analysis of the effects of dams and their associated reservoirs upon the world's rivers. Attention is focused upon the river system downstream of the dam, including its floodplain, estuary or delta, and even the near-shore coastal zone. The author demonstrates with the aid of worldwide examples that dramatic and far reaching environmental changes are the consequence of damming rivers and identifies the considerations that are necessary at the planning stage for the effective evaluation of alternative schemes.

Series: Environmental Monographs and Symposia.
Convener and General Editor. Nicholas Polunin, CBE

0471 10306 3 328pp December'84 £24.50

SOILS AND QUATERNARY LANDSCAPE EVOLUTION

edited by **J. Boardman,** *Humanities Department, Brighton Polytechnic, East Sussex*
Sponsored by **The Quaternary Research Association**

Examines a period of spectacular environmental change, the Quaternary, with respect to soil-landscape relationships in Western Europe, the British Isles and North America. The possibilities for using soils as climatic indicators in the same way as fossils are discussed. The major themes emerging from the book are: the importance of soil stratigraphy in understanding Quaternary sedimentary sequences; the problems of soil-dating and the significance of soil colour; and the growing realisation of the importance of cold-climate processes in soil formation in Western Europe.

0471 90528 3 402pp April'85 £33.00

SPOT TEST ANALYSIS: Clinical, Environmental, Forensic and Geochemical Applications

by **E. Jungreis,** *The Hebrew University of Jerusalem*

Deals with the contemporary utilization of simple spot and screening tests in the clinical, forensic, geochemical soil, food and water testing and occupational safety protection. Equipped with detailed procedural data, it is ideal for use as a laboratory reference source. The book discusses the advantages and disadvantages of quick and inexpensive preliminary spot tests.

Series Chemical Analysis, Volume 75

0471 86524 9 330pp March'85 £76.00

REGULATION AND DEVELOPMENT OF MEMBRANE TRANSPORT PROCESSES

edited by **J.S. Graves,** *Medical University of South Carolina*

Written by distinguished researchers in physiology, biochemistry, genetics, and pharmacology, this state-of-the-art assessment describes the means by which cell membrane transport systems are regulated in both epithelial and nonepithelial cells. It leads readers from a physiological description of regulation towards a more mechanistic level of understanding and is designed to acquaint the reader to the mechanisms involved in the regulation of transport systems, and to stimulate further research.

Society of General Physiologists Series, Volume 39

Contents: Regulation of Membrane Transport; Regulation of Epithelial Transport; Membrane Transport During Differentiation.

0471 81038 X 304pp March'85 £48.30

NONVESICULAR TRANSPORT

edited by **S.S. Rothman,** *University of San Francisco,* and **J.J.L. Ho,** *V.A. Medical Center, San Francisco*

Presents a range of articles on varied topics that consider evidence for the existence of nonvesicular transport for processes that have generally been considered to be carried out by means of vesicle mechanisms, particularly for the movement of proteins and neurotransmitters across membranes. The contributors base their hypotheses on knowledge of the kinetic, thermodynamic, and compartmental characteristics of a process in real space-time, independent of specific models that attempt to explain it.

0471 86570 2 406pp March'85 £90.60

TRANSAMINASES

edited by **P. Christen,** *Universitat Zurich* and **D.E. Metzler,** *Iowa State University*

This is a unique source of comprehensive information covering the properties and functions of transaminases (aminotransferases) and their co-factor pyridoxal phosphate (a derivative of vitamin B6), from a variety of sources. It provides the most up-to-date information on the three-dimensional structures of the aspartate aminotransferases as well as chapters on reaction mechanisms, suicide inactivators, metabolic functions, cell-biological features, and clinical significance.

Series: Biochemistry: A Series of Monographs, Volume 2

0471 08501 4 670pp March'85 £158.00

RECOMBINANT DNA METHODOLOGY

by **J.R. Dillon,** *Laboratory Centre for Disease Control, Ontario,* **A. Nasim,** *National Research Council,* and **E.R. Nestmann,** *Environmental Health Centre, Ontario*

Presents an in-depth look at recombinant DNA methodology, geared for senior undergraduates and graduate students majoring in the biosciences. Basic techniques and alternative methods in recombinant DNA methodology are discussed. The book focuses on the application of techniques, including introductory and background material for each technique, and provides the "how" and "why" of the manipulations to give training and understanding in the field. It presents tested, step-by-step methods for different techniques and experiments, and covers site-directed mutagenesis and yeast cloning. Tips on trouble-shooting are also provided.

Reader Service No.14

ACADEMIC PRESS

A Wide Range of Titles for the Spring...

A Volume in the Behavioural Medicine Series

GASTROINTESTINAL DISORDERS:

Behavioural and Physiological Basis for Treatment

W. E. Whitehead and M. M. Schuster

1985, 312pp., $39.00/£31.50 (UK only), ISBN: 0.12.747030.1

This book provides a long-needed interdisciplinary approach to the assessment and treatment of disorders which presently account for 2.4% of all hospital admissions. There are few physicians trained to manage the psychological aspects of these diseases, and the authors here attempt to close this gap by presenting a comprehensive review and evaluation of behavioural and physiological techniques for the diagnosis and treatment of G.I. disorders. This will be an excellent reference manual for clinicians, and will also be essential reading for academic and clinical gastroenterologists, psychologists, psychiatrists, internists, and family practice physicians.

VETERINARY IMMUNOLOGY

P. M. Outteridge

1985, 288pp., $45.00/£36.00 (UK only), ISBN: 0.12 531130.3

This book is about the immunology of animals of veterinary interest, in particular those of economic importance, such as the ruminant. It is directed towards laboratory workers and post-graduate students wishing to apply basic immunology to veterinary problems. The book places some emphasis on the practical problems of vaccination and diagnosis of infectious diseases. An appendix of methods is included to encourage workers to try new techniques.

Society for Applied Bacteriology Technical Series, Number 21

ISOLATION AND INDENTIFICATION OF MICRO-ORGANISMS OF MEDICAL AND VETERINARY IMPORTANCE

Edited by: C. H. Collins and J. M. Grange

1985, 387pp., $55.00/£42.00 (UK only), ISBN: 0.12.181460.2

The isolation and identification of pathogenic micro-organisms, and their detection by cultural or serological methods is essential to the diagnosis, treatment and prevention of infection. This volume is an up-to-date compilation of such methods used by experienced microbiologists.

SYMMETRY IN BONDING AND SPECTRA:

An Introduction

B. D. and C. A. Hollingsworth

1985, 480pp., $39.00/£32.50 (UK only), ISBN: 0.12.221340.8

The necessary mathematical background for the study of symmetry includes vectors, matrix algebra, and group theory. In this book, the authors have included all of the essential maths for the benefit of students who may need it. Since it is the authors' objective to enable students to handle applications to chemical bonding and spectroscopy, only the required parts of group theory are discussed. However, it is symmetry which receives the greatest emphasis in this book, and all advanced undergraduate and graduate students in inorganic chemistry dealing with symmetry, bonding, and group theory should have a copy of this book.

PREFERRED ORIENTATION IN DEFORMED METALS AND ROCKS:

An Introduction to Modern Texture Analysis

Edited by H.-R. Wenk

1985, 640pp., $59.00/£48.00 (UK only), ISBN: 0.12.744020.8

Determination and interpretation of the preferred orientation of crystals in deformed polycrystalline aggregates has been of longstanding concern to both materials scientists and geologists. This volume serves as an introduction for those who wish to enter this field as well as reviews for those who are already engaged in advanced research.

TREATISE ON MATERIALS SCIENCE AND TECHNOLOGY

Treatise Editor: H. Herman

Volume 26, Glass IV

Edited by M. Tomozawa and R. Doremus

1985, 344pp., $69.50/£56.00 (UK only), ISBN: 0.12.341826.7

This is the fourth volume in a series on glass and together these four volumes represent an introduction to the most significant findings in glass science and technology today.

Microelectronics and Signal Processing Series

SECURE SPEECH COMMUNICATIONS

H. Beker and F. Piper

1985, 262p., $39.50/£32.50 (UK only), ISBN: 0.12.084780.9

The ability to communicate by speech over long distances has become a fundamental part of modern society. However, many means for communicating speech are susceptible to interception and/or intentional corruption, and this susceptibility has increased as modern technology has led to the introduction of new methods of speech transmission. This book discusses the problems, describes current techniques, and looks at the principles involved in designing and assembling secure speech transmission systems.

INTEGRATED TECHNOLOGY FOR PARALLEL IMAGE PROCESSING

Edited by S. Levialdi

1985, 256pp., $39.50/£29.50 (UK only), ISBN: 0.12.444820.8

This book is based on a workshop on "Multiprocessor Architectures for Image Analysis," held in Polignano, Italy in June 1983. Papers from leading academic, government, and commercial research centres illustrate the many different approaches being taken to solve problems in designing organized collections of processors of varying complexity and integrating them into chips.

PHOTOGRAPHY FOR THE SCIENTIST

Second Edition

Edited by R. A. Morton

1984, 560pp., $98.00/£76.00 (UK only), ISBN: 0.12.508370.X

Since the last edition of *Photography for the Scientist* there have been considerable advances in photographic technology such as new highly-automated equipment and enhanced sensitivity of emulsions. This book, an update of the previous edition, provides all the necessary information for the scientist who needs to record and communicate research findings through this medium.

FUNDAMENTALS OF AIR POLLUTION

Second Edition

A. C. Stern, R. W. Boubel, D. B. Turner, and D. L. Fox

1984, 544pp., $39.50/£33.00 (UK only), ISBN: 0.12.666580.X

Solutions Manual

1984, 48pp., $7.50/£6.00 (UK only), ISBN: 0.12.666581.8

Fundamentals of Air Pollution, Second Edition, a textbook for undergraduate and graduate level courses in air pollution, covers elements, sources, effects, measurement, monitoring, meteorology, and regulatory and engineering control of air pollution. Existing knowledge of these topics is reviewed, and the book is updated to include acidic deposition, long-distance transport, atmospheric chemistry, and mathematical modelling.

BRINES AND EVAPORITES

P. Sonnenfeld

1984, c.580pp., $75.00/£60.00 (UK only), ISBN: 0.12.654780.7

The book leans heavily on the physics and chemistry of brines and precipitates. It will thus be of interest not only to sedimentologists dealing with salt sequences but also to low-temperature geochemists. Chapters on the peculiar properties of associated clays, metals, and organic matter should be of special interest to engineering geologists dealing with mixed-layer clays, to economic geologists searching for base metal deposits, and to petroleum geologists.

DYNAMICAL SYSTEMS AND CELLULAR AUTOMATA

Edited by J. Demongeot, E. Goles and M. Tchuente

1985, 382pp., $39.50/£31.00 (UK only), ISBN: 0.12.209060.8

The study of the dynamical behaviour of cellular automata brings together scientists from many disciplines: mathematics, theoretical biology, computer science and physics to name but a few. This volume summarizes their most recent theoretical and practical work.

BIOGENETICS OF NEUROHORMONAL PEPTIDES

Edited by: R. Håkanson and J. Thorell

1985, 295pp., $42.00/£32.50 (UK only), ISBN: 0.12.317450.3

The volume provides a state of the art review of the mechanisms of biosynthesis of neurohormonal peptides as discovered by the most up-to-date techniques of biochemistry and molecular biology with projections to the future.

A FEMS Symposia Publication

ENVIRONMENTAL REGULATION OF MICROBIAL METABOLISM

Edited by I. S. Kulaev, E. A. Dawes, and D. W. Tempest

1985, 420pp., $49.00/£38.00 (UK only), ISBN: 0.12.428580.5

The interaction of microorganisms with their environment is of fundamental interest and importance. Topics covered include the metabolic regulation of heterotrophs and autotrophs, the regulation of cell wall biogenesis and other structures in prokaryotes and eukaryotes, the control of secretion of macromolecules, and the transport processes of solutes and metabolites across membranes.

MOLECULAR CYTOLOGY OF ESCHERICHIA COLI

Edited by Professor N. Nanninga

1985, 376pp., $69.00/£53.00 (UK only), ISBN: 0 12.513950.0

The organism, *E. coli* which is much studied in many disciplines has only recently been known in an integrated way.

This book sets out to reveal the dynamic nature of the structural organization of its organelles and cell parts and to elucidate the mechanisms of cell growth using modern techniques of cell analysis.

A Volume in the Educational Technology Series

DESIGNING USABLE TEXTS

Edited by T. M. Duffy and R. Waller

1985, 432pp., $48.00/£38.50 (UK only), ISBN: 0.12.223260.7

BIOLOGY OF MENOPAUSE

The Causes and Consequences of Ovarian Ageing

R. G. Gosden

1985, 188pp., $37.50/£29.00 (UK only), ISBN: 0.12.291850.9

All the diverse aspects of ovarian ageing in our own species and in animal models have been brought together for the first time in this concise volume. The physiological and biochemical processes responsible for the deterioration of ovarian function, the consequential loss of fertility, and somatic effects of postmenopause are fully explained for biologists interested in reproduction and gerontology and for clinicians concerned with fertility in middle age and hormone replacement therapy.

AUTOIMMUNITY AND THE THYROID

Edited by P. G. Walfish, J. R. Wall, and R. Volpe

1985, 480pp., $44.00/£35.50 (UK only), ISBN: 0.12.731950.6

The proceedings of the International Satellite Meeting which took place after the VIIth International Congress of Endocrinology in July, 1984. The material represents a state-of-the-art presentation of selected aspects of immune regulation and its role in autoimmune thyroid diseases. Also included are the fifty short communications included in the Satellite Meeting itself.

PRINCIPLES OF METASTASIS

L. Weiss

1985, 416pp., $52.00/£43.00 (UK only), ISBN: 0.12.742820.8

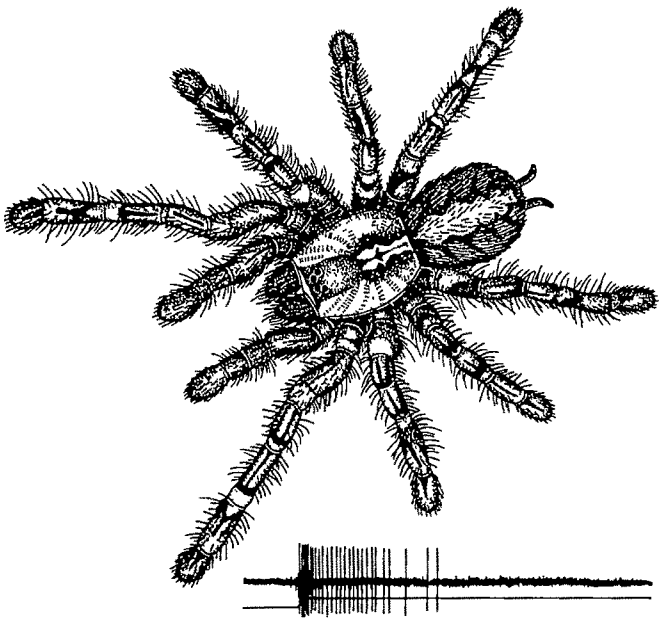
The purpose of this book is to describe the various components of the metastatic process in pathologic sequence and to discuss the underlying principles. Basic and clinical researchers in cancer, and cell biologists will find the format of the book both thought-provoking and informative.

A Volume in the Materials Science and Technology Series

SYNTHETIC MODULATED STRUCTURES

Edited by L. L. Chang and B. C. Giessen

1985, 520pp., $87.00/£70.00 (UK only), ISBN: 0.12.170470.X



This volume is intended primarily as a reference book for workers in the general area of modulated structures; however, it contains sufficient tutorial material to serve as an introduction as well. It is hoped that this book will be useful in offering new perspectives in specialized fields and that others will be stimulated to enter this exciting frontier area of research.

New titles... spun by Springer

Neurobiology of Arachnids

Editor: **F. G. Barth**

1985 162 figures Approx 400 pages
Hard cover DM 198,- ISBN 3-540-15303-9

Contents: Preface. - The Central Nervous System: Structure and Development. - Structure and Function of Sensory Systems. - Senses and Behavior. - The Motor System. - Neurobiology of a Biological Clock.

Leukemia

Editor: **I. L. Weissman**

1985 4 photographs, 15 figures, 19 tables X, 316 pages
(Dahlem Workshop Reports, LS 30)
Hard cover DM 48,- ISBN 3-540-13415-8

Leading scientists in the areas of normal and neoplastic hematolymphoid differentiation, clinical aspects of leukemia, and viral oncogenesis met to try to pinpoint the key factors involved in normal hematolymphoid proliferation and differentiation and in how leukemogenic events disrupt these normal controls.

Concepts in Viral Pathogenesis

Editors: **A. L. Notkins, M. B. A. Oldstone**

1984 26 figures XVIII, 409 pages
Hard cover DM 94,- ISBN 3-540-90982-6

The foremost authorities have prepared 53 chapters, each a pithy mini-review editorial of a key topic, stressing concepts and mechanisms, unresolved problems and future directions of viral pathogenesis. These in turn are systematically arranged to provide a conceptual core of up-to-date knowledge. Viral diseases best exemplifying important or novel virus-host interactions - Human T cell leukemia, herpes, diabetes, Kuru and more - are selected for discussion.

Antarctic Nutrient Cycles and Food Webs

Editors: **W. R. Siegfried, R. M. Laws, P. R. Condy**

1985. 362 figures, 256 tables. XIV, 700 pages (Proceedings in Life Sciences)
Hard cover DM 168,- ISBN 3-540-13417-4

Contents: Introduction. - Marine Nutrient Cycles. - Terrestrial and Freshwater Nutrient Cycles. - Marine Food Webs. - Terrestrial Food Webs. - Interactions between Marine, Freshwater and Terrestrial Systems. - Summary and Conclusions. - Participants in the Symposium. - Subject Index.

K. Reise

Tidal Flat Ecology

An Experimental Approach to Species Interactions

1985. 69 figures Approx 210 pages (Ecological Studies, Volume 54)
Hard cover DM 98,- ISBN 3-540-15447-7

Contents: The Tidal Flat Ecotone. - Experiments on Tidal Flats. - References. - Index.

Exploitation of Marine Communities

Editor: **R. M. May**

1984 4 photographs, 42 figures, 14 tables 370 pages (Dahlem Workshop Reports, LS 32). Hard cover DM 48,- ISBN 3-540-15028-5

This volume surveys our current level of understanding of the dynamics of multispecies marine ecosystems and explores some of the implications for fisheries management. It should appeal to those interested in ecology, marine biology, oceanography, economics, population biology, international law, applied mathematics, and resource and fisheries management.

Sedimentary and Evolutionary Cycles

Editors: **U. Bayer, A. Seilacher**

1985. VI, 465 pages. (Lecture Notes in Earth Sciences, Volume 1)
Soft cover DM 65,- ISBN 3-540-13982-6

Contents: Introduction. - Sea-Level Changes: General Consequences. - Sedimentary Trends in Marginal Epicontinental Basins. - Evolutionary and Ecological Replacements in Marginal Epicontinental Seas. - Gastropod Evolution in Lakes: A Program. - The Lower Hierarchy of Cycles: Spatial and Temporal Substrate Gradients. - Ecological and Morphological Gradients. - Addresses.

G. Gottardi, E. Galli

Natural Zeolites

1985 218 figures. Approx 400 pages. (Minerals and Rocks, Volume 18)
Hard cover DM 160,- ISBN 3-540-13939-7

The book's coverage includes: a revised description of zeolite framework topologies and a new zeolite classification system; a detailed consideration of the deviations between real structures and topological structures; the variability of chemical composition, synthesis and ion exchange apacity; data on physical and optical properties, occurrence, and genesis of all natural phases; thermal curves and X-ray powder patterns.

Announcing a New Series:

Current Topics in Medical Mycology

Volume 1
Editor: **M. R. McGinnis**

1985 Approx 88 figures Approx 360 pages
Hard cover DM 260,- ISBN 3-540-96095-3

Contents: F. W. Chandler: Pathology of the Mycoses in Patients with the Acquired Immunodeficiency Syndrome (AIDS) - **G. H. Fleet:** Composition and Structure of Yeast Cell Walls. - **M. N. Guentzel, G. T. Cole, L. M. Pope:** Animal Models for Candidiosis. - **T. Kaaman:** Dermatophyte Antigens and Cell-Mediated Immunity in Dermatophytosis. - **J. W. Murphy:** Natural Cell-Mediated Resistance against *Cryptococcus neoformans*. A possible Role for Natural Killer (NK) Cells. - **F. C. Odds:** Biotyping of Medically Important Fungi - **E. Reiss, M. Huppert, R. Cherniak:** Characterization of Protein and Mannan Polysaccharide Antigens of Yeasts, Moulds and Actinomycetes. - **J. W. Rippon:** The Changing Epidemiology and Emerging Patterns of Dermatophyte Species. - **G. San-Blas:** *Paracoccidioides brasiliensis*: Cell Wall Glucans, Pathogenicity, and Dimorphism. - **D. R. Soll:** The Role of Zinc in *Candida* Dimorphism. - **R. B. Wickner:** Killer Yeasts. - **H. van den Bossche:** Biochemical Targets for Antifungal Azole Derivatives, Hypothesis on the Mode of Action.

Clinical Pharmacology of Antianginal Drugs

Editor: **U. Abshagen**

1985 81 figures XVI, 552 pages
(Handbook of Experimental Pharmacology Continuation of Handbuch der experimentellen Pharmakologie, Volume 76)
Hard cover DM 460,- ISBN 3-540-13110-8

This volume reviews the epidemiology, pathophysiology and especially the treatment of coronary heart disease.

Laboratory Procedures in Clinical Microbiology

Editor: **J. A. Washington II**

2nd edition 1985 117 figures, 131 tables XIV, 885 pages
Hard cover DM 280,- ISBN 3-540-96087-2

This second edition has been updated to include the newest concepts in and approaches to specimen collection, bacterial nomenclature and identification, chlamydial and viral detection, fungal serology, parasitic identification, antimicrobial susceptibility testing and assay, and laboratory safety.

J. Tiwari, P. I. Terasaki

HLA and Disease Associations

1985 23 figures Approx 456 pages
Hard cover DM 236,- ISBN 3-540-96081-3

This book presents an up-to-date and comprehensive analysis of data on HLA and disease associations published during the last 13 years. The total bibliography of about 4000 papers published on more than 530 diseases is the most extensive to date.

Dyskinesia - Research and Treatment

Editors: **D. E. Casey, T. N. Chase, A. V. Christensen, J. Gerlach**

1985 55 figures Approx 40 tables Approx 235 pages
(Psychopharmacology/Supplementum 2)
Hard cover DM 98,- Reduced price for subscribers to the journal "Psychopharmacology" Hard cover DM 78,40 ISBN 3-540-15009-9

Dyskinesia - Research and Treatment summarizes our most current information about research and treatment of dyskinesias, spanning both preclinical (biochemical and behavioral) and clinical aspects. The chapters are written by the foremost authorities in their respective fields with a good balance struck among new, controversial and well established aspects of specific topics Each chapter can be read as a free standing article or in conjunction with the accompanying chapters. The large majority of chapters are about tardive dyskinesia, but several are devoted to anti-parkinsonism drug-induced dyskinesias and idiopathic dystoma and dyskinesias.

Growth and Differentiation of Cells in Defined Environment

Proceedings of the International Symposium held in Fukuoka, Japan on September, 2-6, 1984

Editors: **H. Murakami, I. Yamane, D. W. Barnes, J. P. Mather, I. Hayashi, G. H. Sato**

1985 XX, 484 pages
Hard cover DM 148,- ISBN 3-540-15061-7
Distribution rights for Japan Kodansha Ltd, Tokyo

In this book emphasis is placed on recent advances in primary cultures and the establishment of new cell lines, on factors for growth, attachment and transport, and on lymphoid cells and hybridomas for antibody production.

Rabies in the Tropics

Editors: **E. Kuwert, C. Merieux, H. Koprowski, K. Bögel**

1985 202 figures 363 tables XVIII, 786 pages
Hard cover DM 148,- ISBN 3-540-13826-9

Rabies in the Tropics gives a clear picture of our present knowledge of rabies molecular biology and vaccine research, as well as vaccination and elimination programs. The latest immunological developments for rabies control in man and animals are reported, and the known rabies virus strains are antigenically characterized by monoclonal antibody differentiation methods.
As the only in-depth report of its kind, this work will become a basic reference for the World Health Organization and a necessary addition to the literature for all those involved in the study and control of rabies.

Spring Books

Biochemistry

Proceedings of the 16th FEBS Congress

Edited by Yu. A. Ovchinnikov

The 16th Meeting of the Federation of European Biochemical Societies was held in Moscow in June 1984. The Proceedings, published in three parts, are an edited collection of the papers presented at the 21 constituent symposia. Contributions are by leading biochemists, often summarizing results drawn from their own work. The books thus represent a 'state-of-the-art' report on biochemical research and, as such, should be available in every biochemistry department and library

Progress in HPLC Volume 1: Gel Permeation of Proteins and Peptides

Edited by H. Parvez, Y. Kato and S. Parvez

High-performance liquid chromatography (HPLC) is a powerful technique used for the separation and characterization of peptides, proteins and enzymes. This book provides a comprehensive and critical review of the current analytical application of HPLC to these substances. The chapters are written by acknowledged experts in the field.

June 1985; x+217pp

Polyamines: Basic and Clinical Aspects

Edited by K Imahori, F Suzuki, O Suzuki and U. Bachrach

The Proceedings of a Satellite Symposium of the 3rd International Congress on Cell Biology, Japan, August 1984

Contains over 60 papers on the following areas: the metabolism of polyamines; the effect of polyamines on cellular metabolism; inhibitors of polyamine metabolism and their clinical relevance; application to diagnosis and prognosis

April 1985; xvi+528pp

Neuroscience

Progress in Neuroendocrinology Volume 1: Neuroendocrinology of Hormone–Transmitter Interactions

Edited by H Parvez, S Parvez and D. Gupta

The book provides a comprehensive discussion of the crucial interface between central neurotransmitter regulation and interacting hormonal pathways. Includes contributions on the cellular interactions of neurotransmitters to induce specific release of a peptide hormone, developmental neuroendocrinology and neurohormonal control of the ovarian cycle.

June 1985, x+297pp

Progress in Alcohol Research Volume 1: Alcohol, Nutrition and the Nervous System

Edited by S. Parvez, Y. Burov, H. Parvez and E Burns

This book provides a comprehensive yet concise review of all aspects of alcohol research. Contributions cover the following areas: the influence of alcoholism on the developing nervous system; critical analysis of new theories involving catecholamines and opiates with alcoholism; role of nutritional factors; biochemical analysis of alcohol effects on microcirculation.

The Pain Clinic I: Proceedings of the First International Symposium

Edited by W. Erdmann, T. Oyama and M. J. Pernak

This symposium, held in Delft in 1984, provided an international forum at which clinicians could exchange new ideas and experiences and discuss the latest methods of pain treatment. The book will be of interest and value not only to the pain clinician but also to the many other biomedical specialists for whom the topic of pain is of prime concern.

extreme uncreativity — the blind repetitiveness of instinctive behaviour shown by the wasp *Sphex*. Typically, he gives this behaviour a name: sphexishness. Its opposite, mental flexibility, he calls anti-sphexishness; and to illustrate the notion he positions various machine, animal and human behaviours along a continuum connecting these extremes. The essence of anti-sphexishness, says Hofstadter, is the ability to break out of loops and ruts of all

Hofstadter — love of word-play.

kinds. He has a word for this, too: "jootsing" (jumping out of the system). It depends, he argues, on watching what you're doing, so as to break up any routine which is getting repetitive. This leads into his favourite topic of self-watching and self-referencing systems, recursive theorems and computer-routines, and the use of recursiveness in "creative" computer programs. He ultimately concludes that some sort of Gödel theorem forbids any exhaustive formalization of creative ability. Any conceivable creative genius or artificially intelligent program must ultimately remain a prisoner of its own style — just like the humble *Sphex*.

In the postscript to this Thema, Hofstadter throws out some intriguing remarks about the subtleties of "style" (What makes a tune catchy? Why do tradenames such as "Day-glo" and "Turbomatic" now seem vaguely dated?), and comments on a new rival artificial-intelligence strategy inspired not by recursion but by the ideas of statistical mechanics. The reader is directed to related discussions in other Themas.

Hofstadter is no mere armchair theorist. He constantly supports his ideas by appeals to practical experience or to intriguing psychological experiments. Expounding the Turing test for computer intelligence (can you distinguish the computer from a human being by its responses to questions?), he presents a transcript of an actual Turing test, with a delightful surprise ending. His discussion of the "Prisoner's Dilemma" paradox, a sort of mathematical microcosm of the tension between competition and cooperation, is enlivened by accounts of several experimental studies. Two of them were tests caried out by Hofstadter himself on human subjects, the other two were tournaments between computer programs. The tournaments marvellously illuminate the biological concept of the "evolutionarily stable strategy" — the optimum behavioural strategy towards which a group of competing organisms will evolve over the generations. This is used to suggest how socially cooperative creatures could have evolved from a primitive population of warring egotists.

Hofstadter's style of writing has its own pleasures and pleasantries. He loves playing with words; puns, anagrams and literary jokes abound. This almost dangerous infatuation with word-play at times works against him. Three whole chapters are devoted to self-referencing sentences, a self-indulgence quite unjustified by the limited conclusions reached. Another chapter presents numerous examples of literary nonsense, again without any moral that I can see. Set against the commentaries by (for example) Aldous Huxley, George Orwell and John Updike on nonsense-verse considered as a penetrating subversion of the stifling world of convention, this is very thin gruel.

The most serious lapses, though, are political. Hofstadter declares himself a natural activist, easily "fired up" by various good causes. The ones he espouses here, those of nuclear disarmament and feminism, are badly served by his simplistic enthusiasm. His anti-nuclear Thema is a sadly flat and contrived parable, arguing that if enough people devote enough time to denouncing the arms-race, it will go away. Once world leaders realize the complete symmetry of the U.S./S.U. confrontation (there's that word-play again) all will surely be well. His feminist Themas point out that in normal grammatical English usage, "he" can include "she" and so on. He seeks to make this a matter for resentment among women, and guilt in men, by means of an extraordinary attempted mapping from a region of very high guilt-density, that of race relations. Orwell, in his celebrated essay "Notes on Nationalism", remarks that the political bigot's great sensitivity to specific words and phrases probably has overtones of word-magic — the belief that the world can be changed by proper incantation. Despite his fascination with words, Hofstadter is too rational a soul to be a bigot. He admits that he may be over-acting. Certainly all previous attempts to change society by word-manipulation have merely enriched the language's glittering treasure-house of euphemisms and polite evasions.

But this is to carp. Most of Hofstadter's Themas are concerned with his areas of special knowledge and insight, and sparkle with linguistic fun, provocative insights and intellectual challenges. This random walk through his intellectual "home territory" is highly recommended. □

Life with a lighter touch

Martin Gardner

"Surely You're Joking, Mr. Feynman!": Adventures of a Curious Character.
By Richard P. Feynman with Ralph Leighton.
W. W. Norton: 1985. Pp.350. $15.95. To be published in Britain later this year by W. W. Norton.

"THE stories Feynman tells about himself would make a book", an interviewer wrote in 1963. Here, 22 years later, is that book. It is not an autobiography. You will learn nothing from it about the work on quantum mechanics that earned Richard Feynman a Nobel prize in 1965. What you will learn is a great deal about the flamboyant personality of a great theoretical physicist: his amazing range of interests, his unusual hobbies, his enthusiasms and animadversions, his dislike of pompous fools, his unpredictable behaviour and, above all, his fondness for outrageous comedy.

Feynman's famous three-volume *Lectures on Physics*, and his marvellous little book *The Character of Physical Law*, were based on taped lectures. *Surely You're Joking, Mr. Feynman!* is a taping of Feynman's uninhibited conversations over the years with his friend Ralph Leighton. "That one person could have so many wonderfully crazy things happen to him in one lifetime is sometimes hard to believe", Leighton writes in his preface.

The reason they happened is that Feynman has a knack of creating his own adventures. When, for instance, he was a young man at Los Alamos, working on the top secret bomb, he discovered a hole in the perimeter fence. Anyone else would have reported this to the authorities and that would have been the end of it, but Feynman is incapable of passing up a chance for a lark. Out of the main gate he goes, back through the hole, then out again. He keeps this up until the sergeant at the gate suddenly realizes that some strange character is always going out but never coming in.

Feynman's expert ability to pick locks followed naturally from his lifelong passion for puzzles. To demonstrate how loose security was at Los Alamos, he would secretly open the safes of top scientists, leaving little notes that said such things as "I borrowed document LA4312 — Feynman the safecracker". But such idiosyncracies were not appreciated by everyone, least of all the military. When three psychiatrists tried to test Feynman for Army service they quickly found themselves being tested. "How much do you value life?", one of them asked. "Sixty-four", Feynman answered. The Army's final verdict: mentally deficient. (The chapter on this banter, headed

"Uncle Sam Doesn't Want *You*!", is one of the book's funniest.)

My favourite anecdote, however — it's vintage Feynman — concerns a joke his friends once tried to play on him. In Japan Feynman had learned some Japanese, and in Portugal he gave lectures in Portuguese. At a party someone thought it would be amusing to see how this "man of a thousand tongues" would react if a Caucasian lady, who grew up in China, greeted him in Chinese. "Ai, choong, ngong jia!" she said with a bow. Taken aback, Feynman swiftly decided the best thing to do was imitate the sounds she made. "Ah, ching, jong jien!" he replied, returning the bow. "Oh, my God!" the lady exclaimed. "I knew this would happen. I speak Mandarin and he speaks Cantonese!".

From childhood on, anything mysterious or puzzling instantly aroused Feynman's curiosity. Growing up in Long Island, New York, he taught himself how radios work and he became the neighbourhood's youngest radio repair man. He invented ingenious experiments with ants to work out how their brains were programmed. Intrigued by hypnotism, he allowed himself to be hypnotized. To experience out-of-body hallucinations, he floated in a sensory deprivation tank. Always, wherever he was or whatever he did, the wheels in Feynman's brain never stopped whirring. Every experience posed new challenging questions. What goes on here? Why does this work? Can it be done better? The best example echoes Newton and the apple (no, that story isn't a myth). Feynman once watched someone toss a plate in the air and noticed that its wobble went around faster than the plate. It started a train of thought that eventually led to the Feynman diagrams for particle interactions and to the work that won the Nobel award.

The book swarms with delightful glimpses of the famous: Einstein, Bohr, Wheeler, Wigner, Oppenheimer, Teller, Pauli, Compton, Fermi, Gell-Mann and many others. (It is said that the California Institute of Technology, where Feynman has taught since 1950, hired Murray Gell-Mann so Feynman would have someone to talk to.) And it was, apparently, a casual remark of one of them, John von Neumann, that gave Feynman a sense of political detachment that he claims has kept him happy ever since. You don't have to feel responsible, the great mathematician told him, for the state of the world. Not for its social and political insanities, perhaps, but trying to understand how nature works on her deepest level is a responsibility — perhaps pleasure is a better word for what Feynman feels — that he surely has not taken lightly. □

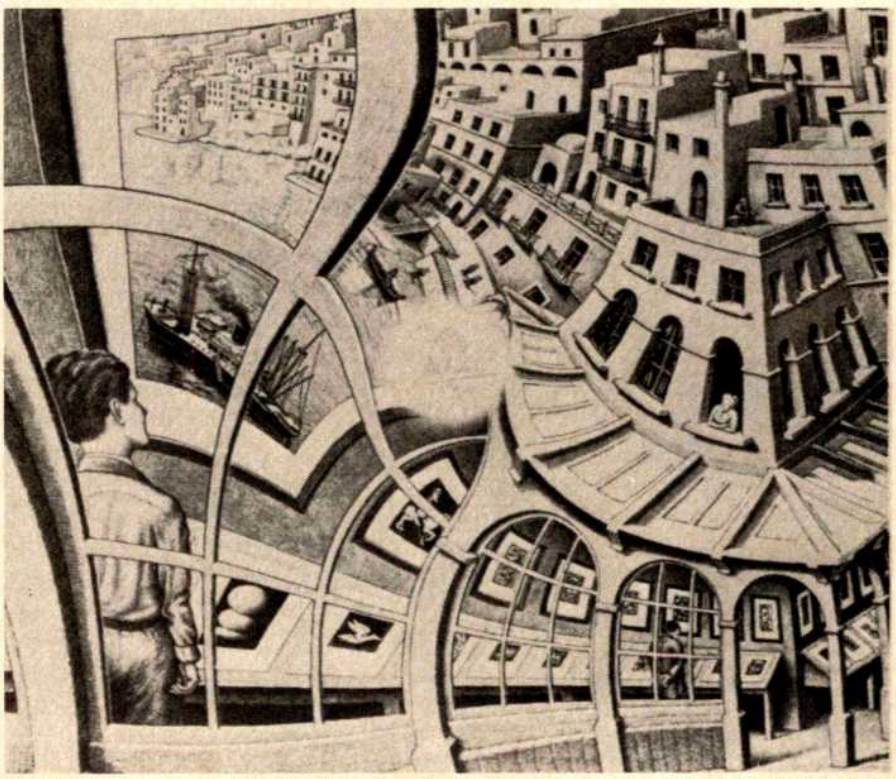
Global matters

David R. Rosseinsky

The Cambridge Guide to the Material World.
By Rodney Cotterill.
Cambridge University Press: 1985. Pp.352. £17.50, $34.50.



"WE are living in a material world" is the burden of a current popular song, and this inviting tome comprehensively portrays its component materials. While — despite the title — not exactly instruction against excessive monasticism (nor yet a coffee-table book, despite the large and colourful jacket) it possibly does have a message underlying its non-mathematical account of materials. Some are materials as in materials science, that is to say mainly solids (metals, polymers, ceramics and the like, together with the new organic superconductors and kindred exotica) but also included are nucleic acids, cells, living systems and their operation. More than a third of the book is devoted to biological materials, metabolism, nerve and brain operation and so on. Perhaps the philosophical drift of this mechanistic outline lies in the concluding sentence — "The nature of the mind remains a mystery". And thereby may the title be nicely justified.

The level of exposition is a mature one, even though for example the concept of potential energy itself has to be established in terms of uphill and downhill travel. Description of nuclear and atomic structures leads on to the complexity of, for instance, the superconductivity mechanism. Experiment is included insofar as it aids the continuity of description. Lively historical exposition is often followed, and individuals are named at a pleasing narrative pace. And there are many fine illustrations, often in colour.

All is not quite perfect, however: we could do without the entropy death of the Universe (yet again), and on the atomic scale some aspects are just wrong rather than oversimplified. Thus p orbitals are not appropriately represented, the hydrogen bond and electron affinity suffer in verbal compression, the invention of the T-jump rate measurement is wrongly ascribed and so on. It is a measure of the book's overall strength, however, that the description of materials, which is the author's *métier*, survives such shortfalls in the physics and chemistry at the beginning.

What will be the readership of such a book? Certainly established physical scientists will benefit (and perhaps feel smart at spotting the occasional slip). But *all* enquiring amateur or professional scientists and technologists of whatever origin or age should enjoy it, and possibly the eye-catching jacket will fulfil the role of the Venus fly-trap depicted there. The price is such as to encourage private investment, and who knows, even as a coffee-table book it could do good by stealth. In Britain the invaluable campaign for "Women into Science and Engineering" goes under the acronym WISE, and for a WISE education, no Material Girl (of the pop song) should be without a copy. □

David R. Rosseinsky is Reader in Physical Chemistry at the University of Exeter.

Churchill Livingstone has books for you this spring

Churchill Livingstone

One of the world's most frequently cited reference books . . . now in an expanded and updated edition

Histochemistry

Theoretical and Applied

Volume Two Analytical Technology

A. G. E. Pearse

Fourth edition 624 pages 299 illus (including 67 colour) hardback £75.00

Key features include:
- new material: some chapters entirely new
- substantially rewritten section dealing with amyloids, reflecting their change in status over the last decade
- formulae and equations revised and re-drawn
- new line drawings and colour illustrations added

An important new series of books . . .
Contemporary Issues in Clinical Biochemistry is an authoritative new series of monographs for the practising biochemist. Each contains detailed accounts of topical areas of investigation by clinical biochemists, with relevant contributions from experts in other fields.

Available now...

Clinical Biochemistry of Alcoholism (Volume 1)

Edited by *Sidney B. Rosalki*

320 pages 31 illus hardback £32.00

Provides an overview of alcoholism in the community, concentrating on its origins and recognition. Effects of alcohol on metabolism and on individual body systems are considered in detail, with particular attention paid to biochemical consequences.

Clinical Biochemistry Nearer The Patient (Volume 2)

Edited by *V. Marks and K. G. M. M. Alberti*

256 pages 77 illus hardback £32.00

Covers: ● in-vivo monitoring in intensive care units ● home monitoring by patients ● legal aspects, costs and implications for future organization and management of clinical biochemistry services

Therapeutic Drug Monitoring (Volume 3)

Edited by *B. Widdop*

372 pages 56 illus hardback £32.00

Guidance is offered on: ● analytical practice ● efficient organization of laboratory resources ● pharmacological and toxic properties of drugs, of their metabolism and distribution ● how these are influenced by age and disease

Also of interest . . .

Recent Advances in Clinical Biochemistry–3

Edited by *C. P. Price and K. G. M. M. Alberti*

312 pages 72 illus hardback £33.00

Edited by two well-known authorities with contributions from 18 experts from the UK, Sweden, Switzerland and West Germany.

Topics covered include: Chemiluminescence in medical biochemistry... Monoclonal antibodies in clinical biochemistry... The investigative value of bile acid measurement in man... Hyponatraemia... The biochemical investigation of respiratory disease... The biochemistry of burn injury... Bedside monitoring: the role of electrodes...

New edition

Biochemistry and the Central Nervous System

Henry McIlwain and Herman S. Bachelard

Fifth edition 668 pages 192 illus hardback £40.00

Within a framework which is primarily biochemical, this text integrates physiological and pharmacological data concerning the central nervous system and its activities in health and disease.

Thoroughly revised and updated — includes new information on:
— amines association with transmission
— amino acids and peptides in neurotransmission
— cyclic nucleotides; mediation and modulation of neurotransmission
— pituitary and hypothalamus
— neurochemical interpretation of the brain

The Urticarias

Edited by *R. H. Champion, M. W. Greaves, A. Kobza Black and R. J. Pye*

256 pages 24 illus hardback £24.00

- Details current, rapidly mounting knowledge on this group of skin complaints
- Points to directions of future progress in their diagnosis, investigation and therapy
- Written by 74 specialists including some of the world's most highly regarded dermatologists

First volume in a vital new series— Current Problems in Tumour Pathology: The Pathobiology of Malignant Disease

Endocrine Tumours

The Pathobiology of Regulatory Producing Tumours

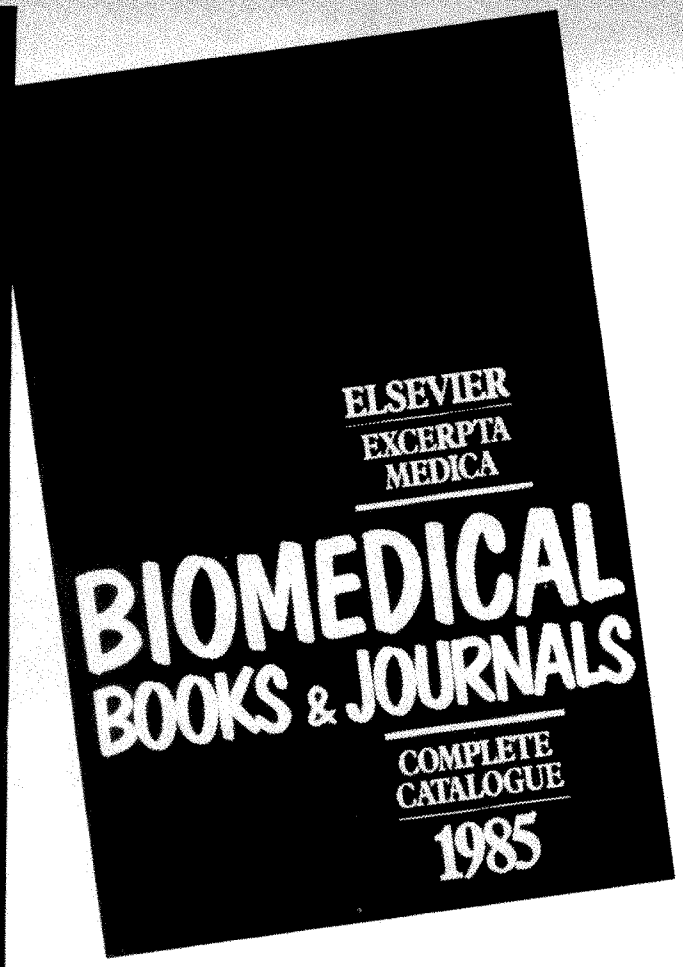
Julia M. Polak and Stephen R. Bloom

304 pages 83 illus hardback £35.00

29 experts from the UK, the USA, Italy, Sweden and Denmark discuss:
- latest advances in molecular and cell biology of regulatory producing tumours
- main features and distribution of regulatory peptides
- clinical and pathological manifestations of neuroendocrine neoplasms

Forthcoming...

Clinical Reproductive Endocrinology



Edited by *Rodney P. Shearman*

Approx. 800 pages illustrated hardback £70.00

Covers all aspects of endocrinology relevant to human reproduction in the neonate, child, adolescent and the adult male and female.

Churchill Livingstone books are available from medical bookshops or, in case of difficulty, direct from the publisher at this address:
Sales Promotion Department, Churchill Livingstone, Robert Stevenson House, 1-3 Baxter's Place, Leith Walk, Edinburgh EH1 3AF. 52GM/NAT

NEW BIOMEDICAL PUBLICATIONS

MIRDAB Microbiological Resource Databank Catalog 1/1985

The first printed edition of MIRDAB contains a total of 601 records of animal cells (general, genetic mutants and hybridomas), plant cells and animal viruses. The information is highly structured to provide specific and relevant data on the cell or virus, its source and availability and an entry to the published scientific literature. Computerization of the data, with a view to future on-line availability when the critical mass warrants it, has enabled the convenient production of an ordered body of information along with two indexes to facilitate rapid retrieval even in the printed catalog.

The Diabetes Annual

edited by **K. G. M. M. Alberti** *and* **L. P. Krall**

This new Annual provides the reader with up-to-date, comprehensive and yet concise, highly critical reviews of the most recent developments in the diabetes area, both clinical and basic.

1985 524 pages
Price: US $ 70.25/Dfl. 190.00
ISBN 0-444-90343-7

Chloroplast Biogenesis

edited by **N. R. Baker** *and* **J. Barber**

TOPICS IN PHOTOSYNTHESIS VOLUME 5.

The aim of this volume is to provide the reader with a knowledge of the major advances in the field of chloroplast development. It comprises a collection of comprehensive review articles on topics of central importance to the understanding of the subject.

1984 xiv + 380 pages
Price: US $ 96.00/Dfl. 259.00
ISBN 0-444-80548-6

Adaptive Mechanisms in Gaze Control

Facts and Theories

edited by **A. Berthoz** *and* **G. Melvill Jones**

REVIEWS OF OCULOMOTOR RESEARCH VOLUME 1

series editors: **D. A. Robinson** *and* **H. Collewijn**

Volume 1 of the new series 'Reviews of Oculomotor Research' provides up-to-date reviews of the behavioural, neurophysiological and theoretical studies concerning adaptation processes in gaze control. The book will be of particular interest to the advanced student, professional research scientist, clinician or teacher.

1985 420 pages
Price: US $ 109.25/Dfl. 295.00
Subscription Price: US $ 92.85/Dfl. 250.75
ISBN 0-444-80483-8

Neural Grafting in the Mammalian CNS

edited by **A. Björklund** *and* **U. Stenevi**

FERNSTRÖM FOUNDATION SERIES VOLUME 5

This volume is the definitive text for workers in the field of neural grafting and for those who intend to explore, or wish to examine, this exciting new avenue of research. The outstanding reviews and original contributions are supplemented by a survey of methodology and an extensive bibliography of most, if not all, of the papers published in the field from 1873 to 1983.

1985 approx. 728 pages
Price: US $ 157.50/Dfl. 425.00
ISBN 0-444-80622-9

The Pharmacology of Inflammation

edited by **I. L. Bonta, M. A. Bray** *and* **M. J. Parnham**

HANDBOOK OF INFLAMMATION, VOLUME 5

series editors: **L. E. Glynn, J. C. Houck** *and* **G. Weissmann**

This is the fifth volume in the already well established series: The Handbook of Inflammation Volume 5 consists of three sections: Effector Mechanisms in Inflammation and Drug Treatment; New Approaches to the Drug Treatment of Inflammation and Monitoring of Anti-Inflammatory Drug Therapy.

1984 approx. 400 pages
Price: US $ 89.00/Dfl. 240.00

Bioenergetics

edited by **L. Ernster**

NEW COMPREHENSIVE BIOCHEMISTRY VOLUME 9

series editors: **A. Neuberger** *and* **L. L. M. van Deenen**

In recent years, research in bioenergetics has increasingly been focused on the reactions involved in the capture and conversion of energy by living cells, in particular those taking place in the energy-transducing membranes of mitochondria, chloroplasts and bacteria. This area, often referred to as membrane bioenergetics, is the main topic of this volume.

Mechanisms of Production and Action

edited by **R. M. Friedman**

INTERFERON VOLUME 3

series editor **N. B. Finter**

This volume is a comprehensive, up-to-date discussion, describing in detail, all aspects of interferon regulation. The work is intended to be a valuable reference volume for libraries and departments of microbiology, virology and immunology. It is also of particular interest to workers in the following fields:– immunology; recombinent DNA, protein chemistry, genetics, molecular biology, pathology, pharmacology, oncology, infectious diseases, and endocrinology.

1985 xx + 396 pages
Price: US $ 92.50/Dfl. 250.00
ISBN 0-444-80581-8

Atlas on Microsurgery of Cerebral Aneurysms

edited by **Zentaro Ito**

This beautiful, carefully designed book is the first to illustrate microsurgical techniques used in the treatment of cerebral aneurysms. The illustrations are complemented by explanations, to enable the neurosurgeon to immediately understand the most suitable operative approach. This work will be a guide in all aspects of surgical techniques in treating aneurysms.

Unwanted Effects of Cosmetics and Drugs Used in Dermatology

2nd Revised edition

edited by **J. P. Nater, A. C. de Groot** *and* **D. H. Liem**

This second edition is even more of an encyclopedia than the first edition, which was recommended in numerous reviews as indispensable for dermatologists in practice, and researchers in dermatology, cosmetics and toxicology alike.

1985 approx. 650 pages
Price: US $ 129.00/Dfl. 348.00
ISBN 0-444-90358-5

Bone and Mineral Research, Volume 3

A yearly survey of developments in the field of bone and mineral metabolism

edited by **W. A. Peck**

The aim of the Bone and Mineral Research Annuals is to provide the research and clinical communities with reviews of the state of the science that are topical, critical and offer insight into future developments.

1984 338 pages
Price: US $ 70.50/Dfl. 190.00
ISBN 0-444-90347-X

Chemistry of Endotoxin

edited by **E. T. Rietschel**

HANDBOOK OF ENDOTOXIN VOLUME 1

series editor: **R. A. Proctor**

Volume 1 of The Handbook of Endotoxin covers the structure, genetics and synthesis of endotoxin and also features some exciting new data on biosynthesis and structure of lipid A.

1984 approx. 420 pages
Price: US $ 89.00/Dfl. 240.00
ISBN 0-444-90384-4

Human Anatomy, Physiology and Pathophysiology

edited by **G. Thews, E. Mutschler,** *and* **P. Vaupel**

This book contains an integrated presentation of human anatomy, physiology and pathophysiology. A General Part deals with functions of the cell and with tissue histology, basic concepts of pathology, transport and excitation processes, and an introduction to medical terminology. A Special Part treats the physiological functions and pathophysiological disorders (diseases) of individual organs.

ELSEVIER - SPRING BOOKS 1985

the practical approach series

DNA cloning (Volumes 1 and 2)

SAVE OVER 10% on two-volume set

Edited by D M Glover, Imperial College of Science and Technology, London

These two volumes supersede previous manuals of cloning techniques by describing recent developments with widespread applications that use *E coli* as the host organism. Chapters cover the use of bacteriophage λ insertion vectors for cDNA cloning and phage λ replacement vector systems to select recombinants for DNA cloning.

Two chapters evaluate *E coli* transformation and methods for *in vitro* mutagenesis of DNA cloning in other organisms, including yeast, plant cells and Gram-negative and Gram-positive bacteria. The last three chapters of Volume 2 offer three different approaches to the introduction of cloned genes into animal cells.

Due May 1985; Volume 1: *200pp (approx); 0 947946 18 7 (softbound); £13.50/US$24.00.* Volume 2: *250pp (approx); 0 947946 19 5 (softbound); £13.50/US$24.50:* Volumes 1 and 2: *0 947946 20 9; £24.00/US$43.00*

Affinity chromatography

Edited by P D G Dean, W S Johnson and F A Middle

A practical manual for biotechnologists and research biochemists of one of the most powerful techniques for separating and purifying molecules and cells. *Affinity chromatography* makes available favourite recipes used by experts in the field. It also includes novel techniques, strategies for developing individual experiments and the theory behind the procedures documented.

March 1985; 232pp; 0 904147 71 1 (softbound); £11.00/US$20.00

Virology

Edited by B W J Mahy, Animal Virus Institute

Virology has been written for molecular biologists, epidemiologists, pathologists and everyone who wants to study animal and plant viruses. Virologists, too, who change their area of specialisation will find the book valuable.

Nine chapters concentrate on how to grow, purify and titrate specific groups of animal viruses. Another chapter describes, in detail, the characterisation and purification of plant viruses. The final chapter covers the techniques of clinical virology, including most standard diagnostic procedures.

April 1985; 280pp (approx); 0 904147 79 8 (softbound); £12.50/US$22.50

Use the reader service card to obtain full details of Practical Approach books and other titles.

The US$ price is valid in the Americas and Japan; the £ price is definitive elsewhere. Prices include postage. Prices are subject to change without notice.

Orders direct to the publisher from outside the UK and Eire must include £1.00/US$2.00 extra per order to cover handling. This charge does not apply to booksellers.

Mutagenicity testing

Edited by S Venitt, Royal Cancer Hospital, Sutton, and J M Parry, University College of Swansea

This laboratory manual of genetic toxicology is a recipe-book of basic techniques for detecting potential mutagens and carcinogens, including those tests laid down by the EEC and OECD.

The book begins by giving the aims and concepts of genetic toxicology. Chapters describe, in great practical detail, nine different tests for detecting mutagenic activity, chromosomal damage and the induction of DNA damage or repair in organisms ranging from bacteria to laboratory rodents. Key references, advice on safety in the laboratory and guidance on presenting and interpreting results are also included.

January 1985; 368pp; 0 904147 72 X (softbound); £14.50/US$26.00

Immobilised cells and enzymes

Edited by J Woodward, Oak Ridge National Laboratory

This is the first book to deal with the practical side of immobilising cells and enzymes.

Clear and precise experimental protocols describe the major methods involved, individual chapters cover specific uses of immobilised cells *eg* in hormone detection and quantitation and in steroid transformation. Other chapters explore their biosynthetic capacity and use in bioelectrochemistry. Throughout, the authors provide specific examples.

Due May 1985; 200pp (approx); 0 947946 21 7 (softbound); £12.00/US$21.50

Plant cell culture

Edited by R A Dixon, Royal Holloway College, London

Plant cell culture provides the knowledge necessary to rationalise the differing responses of different species to culturing and manipulation. Simultaneously it offers effective laboratory-bench methods for particular cases.

The book details how to establish cultures and produce and manipulate protoplasts. The pathways of embryogenesis, organogenesis and regeneration are described, along with vascular differentiation, selection for inhibitor resistance and the formation of secondary products. The book concludes with detailed protocols for cryopreservation of plant tissue and the techniques of phytopathology.

Due May 1985; 250pp (approx); 0 947946 22 5 (softbound); £13.50/US$24.50

Marihuana '84
Proceedings of the Oxford Symposium on Cannabis

Edited by D J Harvey, University of Oxford; Assistant Editors: Professor Sir William Paton and G G Nahas, Columbia University and INSERM

Marihuana '84 contains reviews and papers on the latest marihuana research. The book deals with the pharmacology, metabolism and distribution of marihuana cannabinoids. It places emphasis on their adverse effects, particularly on reproductive functions and the immune response.

Papers cover the analysis of cannabinoids, focusing on the measurement of low levels of them and their metabolites in body fluids. Papers also review potentially therapeutic uses for cannabinoids, *eg* as anti-emetics in cancer chemotherapy.

Due May 1985; 800pp (approx); 0 904147 95 9 (hardback); £55.00/US$99.00 (provisional)

The foot inaudible and noiseless

David Park

Time's Arrows: Scientific Attitudes Toward Time.
By Richard Morris.
Simon & Schuster: 1985. Pp.240. $17.95.

IN THE philosophies of nature that most scientists seem to work out for themselves, time is something of a dark area. Time has extension analogous to space, but the impossibility of experiencing any instant more than once defies analogies — we face great difficulties if we try to define even so simple a word as "now" without tautology. An odd fact is that all this doesn't seem to matter. To use a concept such as *p*H or electric potential we need to understand more or less exactly what is meant, yet we readily navigate the shoals of time even if we cannot explain what we are doing. Our sense of time passing defies explanation in rational terms (how fast does it pass, then?); but we understand perfectly what we are doing when we use a clock.

This being the case, it has often been felt that there is some need for a further explanation of time, and yet in the absence of any practical difficulties one does not quite see what needs to be explained. In *Time's Arrows* Richard Morris adopts a reasonable programme: "We must discover what science can tell us about time before we can know what the relevant philosophical questions are". His remarks on the ancients are mercifully brief. The eye picks out the phrase "the philosopher Pythagoras" and again "Ancient peoples believed that time was cyclic in character" on an early page, and prepares to close in sleep, but pushing on we arrive at Galileo and the incorporation of a time variable, for the first time, in the description of physical phenomena (in this case free fall). Now we are safely in scientific territory. I do not want to encumber this review by enumerating the author's errors, but will mention three examples of the kind of thing that a reader ought not to have to bother with in reading an otherwise illuminating discussion.

- "Galileo was the first to realize that the acceleration of these [falling] bodies was a function of time." Since this remark is made in the context of motion with constant acceleration, I can only attribute it to some demon in the pen.
- "Furthermore, Aristotle said, the velocity at which an object fell was proportional to its weight." This is indeed the conclusion that was widely drawn from passages in Aristotle (for example *Physica* 215[a] and 216[a]), but these make no mention of falling bodies and "Aristotle said" is hardly the way to summarize them.
- In discussing free fall Morris attributes to Galileo the formula $d = \frac{1}{2}at^2$. Galileo never assigned a numerical value to acceleration and wrote no such formula. He did state that d varies as t^2; this is an immediate consequence of the fourteenth-century mean velocity rule. It would have been an interesting paragraph on the history of science if Morris had discussed the fact, surprising today, that the mediaeval scholars did not seek to apply their mathematical formulae to the natural world.

The next chapter is on "Calculus and the Idea of Determinism". After removing the sentence "Today, all of physics and most of higher mathematics are based on calculus", and placing it like a fishbone on the edge of the plate, the reader finds an excellent account of how the invention of the calculus made it possible to extrapolate present motions into the past and future so that the trajectory of a body, as a whole, could become a subject of study. The implications of Laplacian determinism are carefully discussed, though one would have hoped for at least a brief mention of the qualifications of the idea which the researches of the past decade on highly unstable motions have made necessary.

Morris next devotes two chapters to the enormous expansion of the old time-scale stemming from the work of Hutton and Lyell in geology, and Darwin and Wallace in biological evolution, and then moves on to modern physical science. The arrows of the book's title are five in number: the thermodynamic arrow of increasing entropy, the direction of cosmic expansion, the time-asymmetry of weak interactions, the electromagnetic arrow and the psychological arrow. The electromagnetic arrow, which requires that retarded solutions of the wave equation are the only ones to be retained, is the subject of an especially sensible discussion emphasizing that, in a universe containing absorbing matter, either a diverging or a converging wave can be analysed in terms of either advanced or retarded functions; the predicted phenomena are the same in either case, and so the distinction lies outside physics in the mind of the analyst. The psychological arrow involves a real puzzle: how can one understand from all we know of time why consciousness singles out a single instant, now, for its attention?

The last chapters cover the fairly familiar territory of relativity and cosmology. As a whole, this is a somewhat uneven book, serious and thoughtful in places, jejune in others, disfigured by careless errors, but finally, I think, succeeding in what the author sets out to do: to suggest to the reader some of the thoughts that come to the mind of a scientist invited to focus on the word "time". □

David Park is a Professor in the Department of Physics and Astronomy at Williams College, Williamstown, Massachusetts.

But is it art?

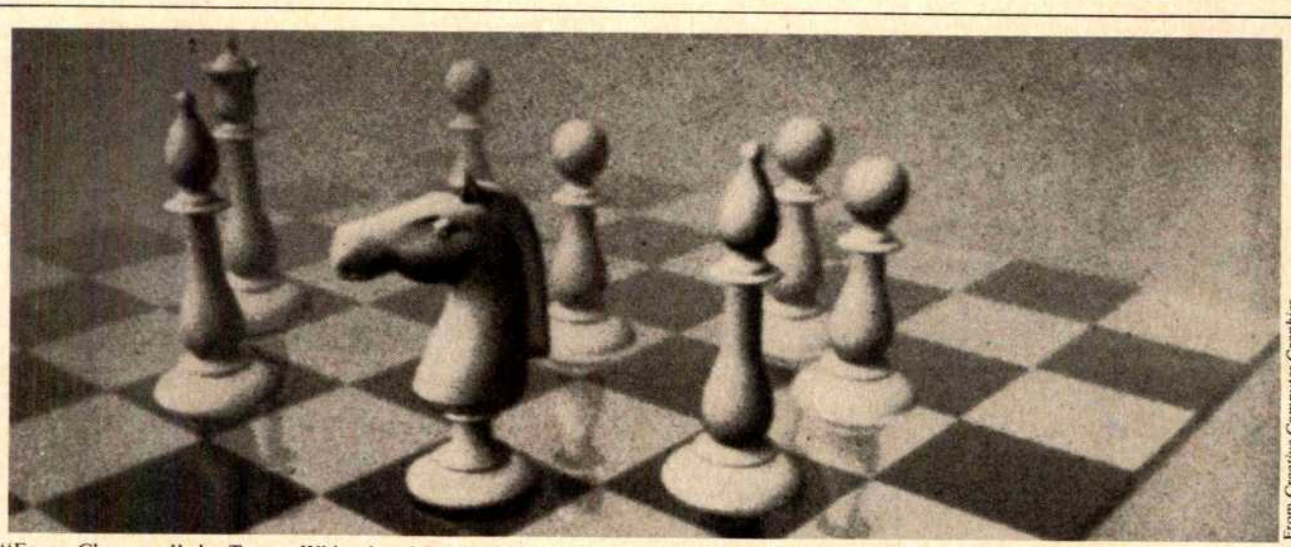
Andrew Dearing

Creative Computer Graphics.
By Annabel Jankel and Rocky Morton.
Cambridge University Press: 1984.
Pp.143. £15.95, $29.95.
Art and the Computer.
By Melvin L. Prueitt.
McGraw-Hill: 1984. Pp.246. Hbk $39.95, £34.75; pbk $29.95, £26.25.

"COMPUTER power" used to refer to the rate at which machines digested numbers. The users were, in the main, scientists, and they generally viewed developments in terms of a new machine's ability to solve bigger problems faster than before. Graphics devices were useful for checking results, but were rarely seen as more than that; there were thought to be better things to do with an expensive computer than use it to draw pictures. Then the price of computers fell, and we finally realized that we could control and understand the computer's calculations better when we could see the problem and the results directly. Equally, quality graphics created a market for personal and small business computers, reaching those for whom numbers held no great appeal, and allowed people working in design, manufacturing and art to discover a new medium with which to express their creativity.

Being creative involves more than producing striking imagery, however. These two books attempt in different ways to examine how computer graphics can be used in this way, and why difficulties are encountered in achieving the desired effects, while presenting a wide selection of pictures that have been produced using the medium.

Jankel and Morton survey many aspects of modern computer graphics technology in order to portray ways in which graphics images can express and communicate ideas, or emulate the natural world. Early chapters trace the history of the discipline, and describe how an object can be modelled within the computer and how these models are converted into images on the screen. Their treatment is non-mathematical, and the novice will have no difficulty following the thread of ideas. Accompanying pictures, which throughout are of the highest quality and generally in colour, complement the text with a refreshing competence and clarity; it would have been all too easy for the authors to rely on the vividness of the pictures to compensate for an anodyne commentary.



Subsequent chapters are devoted to the ways in which computer-generated images are being applied to science, design, art and the media, and used in home computer programs and video games. The authors pay much attention to the technical and human problems of realizing the technique's potential, and there are some amusing insights along the way. One story that appears to be almost apocryphal describes how an attempt to enter a computer-generated print for a New Jersey competition was rejected in 1969, but accepted the following year when the artist presented the same piece as a hand-made silk screen. We often expect too much too soon, and technical novelty must be studied in terms of what is already known, not presented in isolation, before the artist knows how to use the medium and the viewer can understand the context within which he should see the results. Certainly, Jankel and Morton demonstrate that creativity remains the product and responsibility of the craftsman. In spite of the argument that such creativity resides in the programmed sequence of code that produces the image, the best results seem to be those in which computer graphics is used to complement and enhance material obtained using other techniques.

In *Art and the Computer*, Prueitt concerns himself specifically with computer graphics as an art form, and most of his book is used to present a gallery of pictures representative of recent work. He too describes the methods used to generate the images, and analyses their potential as tools for the artist, but somehow neither his pictures nor the commentary really succeed in showing that computer art is yet on a par with more traditional work. Interesting topics are introduced — for example, Prueitt notes how visual appeal often depends on precise use of colour — but he fails to develop the opportunities he has created, and merely repeats his contention that the results can be considered to be art.

It is, however, not sufficient to define art simply as "creative work produced by a person", since that does no more than make us ask what the author means by "creative", and that question is not answered in the book other than by encouraging us to look at the results for ourselves. Yet, although the work reproduced here is twice claimed to be representative of the finest computer-generated art, by its greatest practitioners, over half of the pictures are by the author himself, and are mostly variations on a theme of broken symmetry, resembling pictures viewed in a kaleidoscope or drawn with a child's epicyclic toy. While they show clear technical skill, there is too little sensitivity to the need to define where the art has contributed something new.

Neither of these books offers much that is new to the specialist. Nonetheless, Jankel and Morton have succeeded in portraying the creative use of computer graphics in a way that will interest both layman and professional. Their book should remain an accurate snapshot of the state of this particular "art" in the mid-1980s. □

Andrew Dearing is currently Head of the Molecular Graphics Group at Shell Research Laboratories, Sittingbourne, Kent.

"Foggy Chessmen", by Turner Whitted and David Weimer, produced using scanline algorithms (rather than ray tracing) to produce the shaded effect. Scanline algorithms cannot cope with reflections, and the mirror chessmen are the original ones turned upside down and toned down to give the effect of reflection in a marble chessboard.

Stay current with the latest research

. . . new books from Gordon + Breach & Harwood

Radiopharmacy & Radiopharmacology Yearbook 1

edited by Peter H. Cox
A Gordon + Breach book

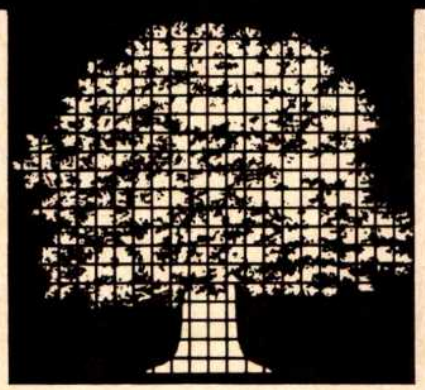
A comprehensive desk-reference annual filled with information on research, new products, manufacturers, publications and scientific meetings.
May 1985 392 pp.
hardcover: 2-88124-114-X $47.00
softcover: 2-88124-113-1 $18.00

L. S. Pontryagin: Selected Works

Volume 1: Research Papers
edited by R. V. Gamkrelidze
Translated from the Russian by Naidu PSV
A Gordon + Breach book

The most important papers of this eminent mathematician, from his early efforts in homology groups, duality theorems, and dimension theory to his later achievements in homotopic topology and optimal control theory.
June 1985 638 pp. hardcover
2-88124-105-0 $255.00

Polymer Yearbook 2



edited by Richard A. Pethrick
A Harwood book

". . . the comprehensive academic library will want to have the series for its annual coverage of polymer science, not otherwise available to an interested reader. The layout, printing, accuracy, coverage and overall quality are excellent."
— Choice
May 1985 420 pp.
hardcover: 3-7186-0274-1 $50.00
softcover: 3-7186-0276-8 $20.00

Nuclear Fact Book

compiled by A. M. Platt, J. V. Robinson & O. F. Hill
A Harwood book

An annual desk reference providing concise summaries and essential facts in

the areas of energy production, consumption and costs as well as nuclear energy production, fuel cycle, and wastes.
April 1985 192 pp. hardcover
3-7186-0273-3 $33.00

Collective Phenomena in Current-Carrying Plasmas

by E. D. Volkov, N. F. Perepelkin, V. A. Suprunenko & E. A. Sukhomlin
A Gordon + Breach book

Written by the famous Khar'kov group, this seminal monograph — published in English for the first time — offers a theoretical and experimental review of anomalous resistance and turbulent heating in current-carrying plasmas.
1984 264 pp. hardcover
2-88124-016-X $90.00

Particle Accelerators and Their Uses

by Waldemar Scharf
Translated from the Polish by Eugene Lepa
A Harwood book

". . . an outstanding contribution to the literature that will be used both by persons working in the field of particle accelerators and by persons in other disciplines who want to know more about this dynamic field." — John P. Blewett & Francis T. Cole
June 1985 approx. 1,000 pp.
hardcover 3-7186-0034-X $195.00

Piezoelectricity

edited by George W. Taylor, Jacques J. Gagnepain, Thrygve R. Meeker, Terutaro Nakamura & Lev A. Shuvalov
A Gordon + Breach book

Covers all aspects of piezoelectricity — from fundamental research to the most recent developments and technology in applications.
April 1985 420 pp. hardcover
0-677-16660-5 $84.00

Introduction to Geomechanics

by J. S. Lee
Translated from the Chinese by Chen Qing-Xuan
A Gordon + Breach book

Treats structural phenomena in the light of a new concept — tectonic systems that fall into various types according to the characteristic pattern they display in the earth's crust.
1984 234 pp. hardcover
0-677-31070-6 $68.00

Contiguity and the Statistical Invariance Principle

by P. E. Greenwood & A. N. Shiryayev
A Gordon + Breach book

Enlarges the scope of contiguity and the related statistical theory by excluding the usual assumptions of independence, Markov character, homogeneity, and so on, and presents a series of new functional limit theorems directed towards inference for stochastic processes.
May 1985 242 pp. hardcover
2-88124-0138-5 $39.00

Chaos in Dynamic Systems

by G. M. Zaslavsky
Translated from the Russian by V. I. Kisin
A Harwood book

Clarifies the most revolutionary significance of stochasticity in such areas of statistical physics as nonlinear wave fields, dynamic Hamiltonian systems and quantum systems.
February 1985 388 pp. hardcover
3-7186-0225-3 $195.00

The completely new
DICTIONARY OF ORGANOMETALLIC COMPOUNDS

. . . and the experts are unanimous!

"This extraordinarily useful compendium is one that no chemical enterprise having the slightest involvement in organometallic chemistry would want to be (or would be wise to be) without."

Professor F A Cotton
Texas A & M University

"In future, if I wish to know whether a certain organometallic compound or type of compound has been made, or to form an impression of the properties of certain types of compound, I will turn first to this *Dictionary*."

Professor C Eaborn
University of Sussex

"One of the most fundamental problems facing the organometallic chemist today concerns rapid information retrieval concerning specific organometallic compounds . . . The *Dictionary of Organometallic Compounds* . . . provides the most expedient approach yet available to these questions."

Professor M Rausch
University of Massachusetts

". . . chemists have long felt the need for such a compilation of data on organometallic compounds . . . an indispensable addition to any chemistry library."

Professor H Sakurai
Tohoku University

"It is difficult to imagine a better recommendation for scarce library funds in institutes and organisations concerned with organometallic chemistry; the hours saved in information retrieval will soon repay the initial outlay."

Professor M I Bruce
University of Adelaide

"I found the volumes very easy to use and the individual sections excellently put together and covering the essential material for each element in a sensible, authoritative, up-to-date and accurate manner. All libraries where chemists work who are interested in metal complexes whether from the synthetic, structural or catalytic point of view, should have a copy of the *Dictionary of Organometallic Compounds*."

Imagined worlds: visions of theoretical physics

David Bohm

Imagery in Scientific Thought: Creating 20th Century Physics.
By Arthur I. Miller.
Birkhäuser: 1985. Pp. 320. $24.95.

THE ultimate origin of creative developments in science, art and in other areas of life will probably remain a mystery, no matter how far our knowledge may progress in the future. Nevertheless, it seems reasonable to suppose that a great deal of light can be shed on the subject by a careful analysis of the process in which new ideas develop in actual historical case-studies. In *Imagery in Scientific Thought* Arthur Miller does this for the field of science, tracing the relationship of creative thinking and the construction of new scientific concepts from pre-scientific knowledge. To this end, he focuses on the work of Poincaré, Einstein, Boltzmann, Bohr and Heisenberg, because these physicists were specifically influenced in their research by their consideration of the nature of thinking itself.

In the book, Miller makes the key point that the major change that took place through the work of these scientists was the development of a fresh attitude towards mathematics and the imagination. Thus, Poincaré's view on the subject was that Euclidean geometry arose necessarily from man's earliest thought because it was needed for his survival. For Poincaré this implied the basically conventional nature of the axioms of geometry. To obtain real content, they have to be enriched with lower-level physical hypotheses. The introduction of such hypotheses is through *invention*, and this comes out of an intuition that cannot be defined explicitly but must be felt. This is a kind of Baconian inductivism with gaps supplied by intuitively guided inventions. Physical theories then express in the most convenient manner the "true relations between real objects" along with the invariant laws pertaining in these relationships.

Einstein adopted much of Poincaré's approach, and explicitly expressed his debt to Poincaré in calling attention to the need to "pay strict attention to the relation of reality and our concepts". However, he rejected Poincaré's *a priori* organizing principles along with his closely related assumption of a fundamental role in our thinking for Euclidean concepts. Rather, he regarded concepts in general as admissible "only to the extent that observable facts can be assigned to them without ambiguity". Thus, for Einstein, the question of whether Euclidean geometry is valid was basically *physical* (for example, that of whether it is possible to attach the Euclidean concept of length to a quasi-rigid measuring rod in an unambiguous way).

Einstein considered science to be essentially a refinement of everyday thinking, in which images are of course involved. He felt it necessary to analyse serious thinking (in contrast to "dreaming") as a series of such images ordered by a recurrent image that constantly turns up. Such an ordering element can relate many different series of hitherto unconnected elements, and this ordering element he regarded as a concept.

Though he seems to have started from Poincaré's approach of building a theory step by step by posing hypotheses to explain the experimental data, Einstein realized by the end of 1904 that the "known facts" were too restricted to solve the problem of an electromagnetic world picture. Instead he shifted to an appeal to general axioms and theories of principle, similar in structure to those of thermodynamics. These were the principle of relativity of motion and the principle of the invariance of the speed of light. Here, Einstein's thought was affected by the views of Boltzmann. For Boltzmann, our mental pictures, which he regarded as abstractions from objects actually perceived, must be clearly and unambiguously imaginable. A striking example of this is Einstein's highly imaginative picture of an observer who moves along with a light wave and sees only a static configuration of fields. The implication of this picture violated Einstein's physical intuition that the electromagnetic field is inherently dynamic, and eventually led to his taking the invariance of the speed of light as a basic principle.

Through the consideration of the properties of dynamos (as well as in other ways) Einstein was then led to regard Lorentz's idea of a local time in terms of which Maxwell's equations were invariant (to first order in v/c) as similarly indicating a general principle, which was the relativity of simultaneity (and which held to all orders in v/c). Here, Einstein was clearly guided by the notion that our ordinary concepts of time can no longer be related unambiguously to the experimental facts when we consider the full implications of electrodynamics (as he showed with the aid of various hypothetical experiments). So he was ready to go against ordinary intuitive experience when he felt this to be necessary, but he still insisted that concepts have to be *some* kind of abstractions from our pre-scientific perceptual experience which must be unambiguous in the senses indicated above.

This brings us to the contributions of Bohr and Heisenberg. Their analyses of the meaning of the quantum theory indicated to them that there are limitations on the possibility of unambiguous intuitive visualizability of the properties of matter at the quantum level. Bohr emphasized the need to separate the space-time and the causal descriptions. This implied that the ordinary imaginative pictures can be retained, but that they have to be *ambiguously* related to experimental facts. Here, perhaps, is the fundamental difference between Bohr and Einstein, who, as we recall, insisted on the need for the possibility of an *unambiguous* relationship between concepts and the experimental facts. In my opinion, it is unfortunate that Miller does not bring this point out in the book, as it is of crucial importance in understanding the split that eventually came about between Bohr and Einstein, a split that profoundly affected the development of quantum theory and relativity.

Heisenberg's initial approach was, in contrast to that of Bohr, to insist that our customary intuitive visualization (*Anschauung*) could not be extended into the atomic domain at all. Miller follows the further development of Heisenberg's approach in some detail, to show how it led eventually to a new notion of intuition and imagination, which Heisenberg called *Anschaulichkeit*. This referred not to ordinary visualization, but rather to the imaginative display of the meaning of the mathematical formalism (which latter was by then regarded as the most direct and fundamental way possible of putting the truth about nature). This mode of visualization is now most commonly encountered in the Feynman diagrams which do not correspond to reflections of actual physical processes, but which serve primarily to enable physicists to think imaginatively about the meaning of the mathematics. As Heisenberg himself said, this is essentially an extension of the Platonic (and perhaps Pythagorean) approach. It may be summed up in the dictum of Jeans: "God is a mathematician".

If one looks at how modern theoretical physics is actually done, one can see that Heisenberg's approach now dominates, not only in particle physics but also in cosmology. Miller's book provides important insight into how the whole way of doing theoretical physics thus altered radically in a comparatively short time. This insight could, however, perhaps have been extended if the author had brought out, even if only briefly, how several centuries ago a similar change occurred, culminating in the Newtonian approach. To have done this would have indicated that what constitutes commonly accepted scientific practice has constantly been changing, and that it may therefore change again in an equally fundamental way. Tacitly to regard the currently accepted way of doing physics as the last word on the subject is to encourage the same sort of absolutist conclusions that took hold of the Newtonian way of doing physics, and thus help to ossify the current approach too.

The latter part of the book is a survey of various attempts of modern psychologists to account for the creative development of modern physics. It begins with a description of Wertheimer's application of Gestalt

psychology to Einstein's process of thinking in the work that led to the theory of relativity (Wertheimer's work drew upon actual discussions with Einstein himself). Miller then goes on to a broader discussion in terms of new researches based on extensions of Piaget's work on genetic epistemology. Two different versions of genetic epistemology are considered here, the first due to Pylyshin and the second to Kosslyn. Pylyshin and Kosslyn are in agreement in that they develop detailed accounts of how imaginative thought actually proceeds and try to support these accounts on the basis of actual case-studies. Their principal disagreement is on the dynamic role of images. Roughly speaking, Kosslyn assigns a positive predictive power to images, while Pylyshin regards them, in effect, as little more than passive displays of abstract propositional thought.

Although Miller gives what seems to be a fair treatment of this whole subject, I feel that he fails to be adequately critical in that he accepts an assumption that seems to be taken for granted in all the work on genetic epistemology. This is that creativity is primarily to be understood through the development of knowledge, enriched perhaps from time to time by *invention* whose source is (along the lines indicated by Poincaré) ultimately in a mysterious intuition. I would like to suggest that while all of these factors are involved in creativity, its primary source is in *perception*, not only through the senses, but, even more, through the mind (as indicated by the Greek *noesis* and the German *Vernunft*, which latter means intuitive or perceptive reason). Kostler gives an example of this, in the sudden realization of Archimedes that the volume of water displaced by a body is the same as the volume of the body independently of the complex details of its shape. Perhaps we could say that Einstein must have similarly realized somehow that the problem with electrodynamics was essentially the same as with thermodynamics; that is, to find principles that are independent of a detailed dynamical description of all the complex processes that are actually at work in concrete experimental situations. It seems to me that a study of the history of the subject from such a perspective is necessary, if we are to have a proper account of how the mind gets out of the "rut" of thinking in terms of old concepts that have long been taken for granted.

I feel that in spite of certain inadequacies Professor Miller has made a valuable contribution to our understanding of creativity in twentieth-century physics. His book is well worth reading by all those who are interested in the history and philosophy of science, or in the understanding of the nature of creativity and its relationship to the process of thought. □

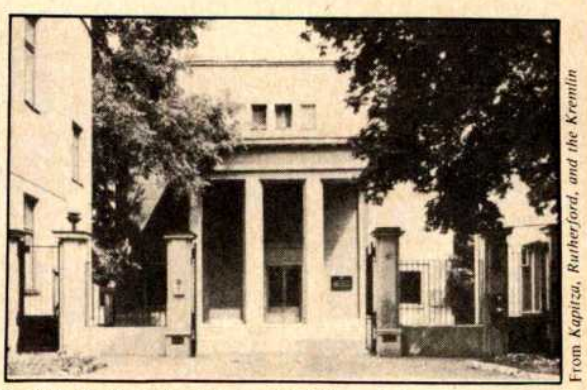
From Cambridge to Moscow

Nevill Mott

Kapitza, Rutherford, and the Kremlin.
By Lawrence Badash.
Yale University Press: 1985. Pp.129. $20, £20.

LAWRENCE Badash has dedicated this book to the memories of Ernest Rutherford (1871–1937) and Peter Kapitza (1894–1984). The story of the relationship between the two men is well-known. Kapitza, a brilliant young pupil of A.F. Joffe in Leningrad, lost his wife and two children in the influenza epidemic of 1921, and, in an effort to rescue him from his deep grief, friends arranged a trip abroad. They were successful; Kapitza knew where he wanted to go and arrived that year in Rutherford's Cavendish Laboratory. The Mond Laboratory was built for him and a Royal Society chair became his. There he developed equipment for producing strong magnetic fields and low temperatures, work on which was to culminate in the award of a Nobel Prize in 1978. The friendship between the two men must have been very deep, particularly as these branches of physics were far away from Rutherford's beloved nucleus.

Kapitza, as I remember, used to boast that he was the only Soviet citizen whose passport was endorsed for unlimited travel in and out of the Soviet Union. In 1934 he went with his second wife Anna to the congress in Leningrad which celebrated the one-hundreth anniversary of the birth of Mendeleef. They took their car to Bergen, and motored through Norway and Finland. I remember this, as I was invited to the conference, probably because I had helped Frenkel with the English version of his book on liquids, and Kapitza suggested that my wife and I should join them in their car (in the event there seemed not to be enough room for us and the luggage, and we went by boat). Once there, Kapitza was told that his country needed him and he must stay. Anna went back to Cambridge, joining him with the children more than a year later.



In the book Badash tells the story of Rutherford's efforts to help him, reproduces many of Kapitza's agonized letters to his wife and to Rutherford, and records how eventually much of the Cambridge equipment was bought by the Soviet government, and how, two years later, he was able to settle down to work in his new Institute for Physical Problems of the Academy of Science. He had the help of two of his technicians from Cambridge, who spent several years with him in Moscow.

Kapitza's misery in his first year, which might have seriously endangered his health, was not because he was unwilling to work for his country; he always protested that he wanted to. It was because, until the Institute was ready, there was nothing he could do. To be cut off from work was dreadful for him. If he could have returned to Cambridge, supervised the transfer of equipment to Moscow, finished off certain researches and indeed been treated like a loyal Soviet citizen, he would not have complained, or at any rate not so bitterly. But — and this is what made life intolerable — he was given no trust. People were afraid to talk to him and so he had few friends. An official was detailed to look after him, and promised much, but when Kapitza's winter clothes were posted to Moscow from Cambridge he could not even get the parcel through customs without Kapitza having to pay a huge import duty. Kapitza was denied Western newspapers, but letters to and from his wife seemed to get through, as did telephone calls. I was once in R.H. Fowler's house when a call came through from Kapitza, which lasted a very long time. Apparently he could at least do that, and trunk calls must have been cheap.

A letter from Kapitza to Rutherford in the early days of the Institute records vividly the difficulties of doing research at that time under the Soviet system:

> You see Soviet industry is growing at a terrific rate and all is done to make its growing organised and well planned, so that all the system of supply and production is also well planned and organised. But the supply of the factory, which is operating according to a definite plan, must be anticipated in details at the beginning of the year, and evidently represents its demands in very large figures. Such a system is indeed quite unsuitable for the supply of laboratories. I have written and spoken to the

From *Kapitza, Rutherford, and the Kremlin*

Peter Kapitza (about 1925) and the Institute for Physical Problems, Moscow.

authorities that the labs must be supplied in a different way, and I think that the people here begin to recognise that the system of supply must be altered for the scientific institutions. But, at present, if for instance we require four bars of phosphor bronze, the need of which we had not anticipated in the beginning of the year, we must get it as an exception and the permission of the sub-secretary of the Heavy Industries is required and this means a lot of correspondence, which is equally extensive if we require 10 kilograms, 10 tons or 10 loads of stuff. And so even if the Institute is given sufficient money, and even if the industries are quite decent, we are actually very badly supplied.

He believed, however, that things would get better. But later he wrote:

My colleagues the scientists are very scared of me and behave like pigs. My institute is attached to the Academy of Science, of which I am not a member but they govern my institute. The president is Karpinsky, he is ninety years old. During meetings of the Council he sleeps with a happy and kind smile on his face.

It is for insights such as these, showing the reactions to Soviet bureaucracy of a great man who had experienced Cambridge, that I recommend this book. Parts of it are compulsive reading. How much the bureaucracy has changed since then is not discussed but in any case Kapitza came to terms with it, became a Hero of Socialist Labour, received several Orders of Lenin and was throughout a sane and courageous voice in Soviet science. One wonders if he would have survived the early days without Rutherford's moral support, and Rutherford's efforts — though unsuccessful — to secure his release, which are here described by Badash. Kapitza repaid some of his debt in his "Recollections of Lord Rutherford", published in the *Proceedings of the Royal Society* in 1966.

Kapitza, then, was back to work by 1936. The author remarks that the timing was fortunate, for Rutherford, upon whom he depended so much for aid and encouragement, died in October 1937. □

Sir Nevill Mott is Emeritus Professor of Physics at the University of Cambridge.

Between machination and merit

Robert Fox

The Beginnings of the Nobel Institution: The Science Prizes, 1901–1915.
By Elisabeth Crawford.
Cambridge University Press: 1985.
Pp.281. £22.50, $34.50.

A FEW days after Alfred Nobel's death in December 1896, his close relatives gathered expectantly for the reading of his will. They were in for a shock. For Nobel had bequeathed to his family a mere one million crowns. The rest of his vast estate, amounting to 30 times that amount (over £1½ million), was to be invested to provide five annual prizes, for physics, chemistry, medicine or physiology, literature, and what Nobel (a convinced pacifist, despite the fortune he had made from explosives) called "contributions to the fraternity between nations". Predictably, the will was contested. But the adjustment that was made in favour of the family was meagre, and in 1901 the first prizes were awarded essentially in accordance with Nobel's wishes.

Elisabeth Crawford traces the difficult birth of the Nobel system and the labyrinthine processes by which the awards were made in physics and chemistry between 1901 and 1915. The sheer size of the prizes, each of them worth about 30 times the annual salary of a university professor, was enough to ensure intense public interest. And the element of spectacle was further enhanced by national as well as personal rivalries which made it difficult for the brash newcomer to integrate with the rather chaste reward system of European science as it existed at the beginning of the century. Tradition demanded, of course, that the cruder rivalries should be concealed. But Crawford penetrates this facade to excellent effect. Drawing on her intimate knowledge of the relevant Nobel archives (open since 1974, in accordance with a new 50-year rule) and of the context and content of Swedish science in the early twentieth century, she casts radically new light on the complex interaction between the dispersed international networks of nominators and the subject committees in Sweden.

Few readers will be surprised by Crawford's demonstration of the keen opposition between the various national traditions in science, for, by 1900, science was emerging as a battle-field on which the European powers were only too ready to try their strength, not least with the disturbing new force in research, the United States. The French, it seems, were especially prone to nominate their fellow-countrymen, far more so than the Germans, who have a commendably low score on Crawford's ingenious index of chauvinism. (Britain's record was mixed, with the physicists appearing distinctly more chauvinistic than the chemists.) However, Crawford's evidence suggests that it was the Swedes themselves who injected the greatest element of competitiveness. Here, the main antagonists were Svante Arrhenius, already distinguished internationally for his work on the theory of solutions, and the mathematician Gösta Mittag-Leffler. The two men were poles apart in their political sympathies and in temperament and lifestyle. Arrhenius was liberal, popular and modest to the point of insecurity about his scientific abilities, whereas Mittag-Leffler was conservative, flamboyant and more respected than liked. As Crawford shows, Arrhenius and Mittag-Leffler intervened rather irregularly, but whenever they felt moved to support a personal preference, or to thwart the candidate of a rival, they acted with rare zest.

In this running confrontation, Arrhenius had a notable early success when he saw to it that the first prize in chemistry went to J.H. van't Hoff, whose work on electrolytic phenomena complemented his own. In 1909, Arrhenius successfully backed another ionist, Wilhelm Ostwald, and, using more negative tactics, he managed to delay an award for his rival Walther Nernst until 1921 (15 years after the first nominations for Nernst had been received). Mittag-Leffler, by contrast, saw his main mission as the advancement of mathematical physics. It was he who secured at least a share in the physics prize for H.A. Lorentz in 1902. And it was only misfortune which denied him his greatest triumph: his long campaign in favour of Poincaré had still not succeeded when Poincaré died in 1912.

Ann Ronan

Arrhenius — "modest to the point of insecurity about his scientific abilities . . .".

These episodes and the intolerance they imply are far from edifying. But generally Crawford's book is reassuring. It provides ample evidence that although animosity, national interest and the stage-managing of nominations all played their part, scientific merit was nevertheless consistently rewarded. It is arguable that a blunder was made in 1908, when the French experimentalist Gabriel Lippmann emerged as a successful compromise candidate, following Mittag-Leffler's mishandling of his own campaign in favour of a joint award to Planck and Wien. But while Lippmann was no Planck, even this decision rewarded excellence of a kind. Like the overwhelming majority of the decisions discussed by Crawford, it seems a beacon of wisdom when compared, say, with the award of the first prize in literature to the poet Sully Prudhomme as a sop to French pride. All told, the physicists and chemists of Europe and North America come out of this intriguing and well-told story with a good deal of credit. □

Robert Fox is British Academy Reader in the Humanities at the University of Lancaster.

On trans-scientific turf

Owen Gingerich

Beyond Velikovsky: The History of a Public Controversy.
By Henry H. Bauer.
University of Illinois Press/Harper & Row: 1985. Pp.354. $21.95, £24.25.

"THE thousands of words spilled to refute and condemn his theories gave them a sort of status, even if only that of divinely inspired nonsense." So the London *Times* summed up the controversy surrounding the work of Dr Immanuel Velikovsky when he died in November 1979.

Basically, Velikovsky claimed that in the ages before Christ a large body had been ejected from Jupiter and had gone into orbit around the Sun, eventually to become the planet Venus. On its way, it came close enough to the Earth around 1500 BC to cause the pharonic plagues of *Exodus* and may other miraculous phenomena recorded in the Old Testament, including the day the Sun stood still at Gibeon. Relying on eclectic interpretations of world-wide mythology, Velikovsky amazed his readers with his erudition and dismayed astronomers by his flagrant disregard for Newtonian mechanics.

The hue and cry against Velikovsky's theory came primarily in two waves. When his principal work, *Worlds in Collision*, appeared in 1950, heralded by sensational abridgements in *Harper's, Colliers* and the *Reader's Digest*, astronomers stirred up such a tempest that Velikovsky's place in the best-seller list was assured. Having learned that any publicity is good publicity, the scientists quickly lapsed into indignant silence, hoping that the interest in Velikovsky's theories would atrophy under their careful lack of attention. Their scheme may well have worked except that Velikovsky was "rediscovered" by the anti-establishment generation of the 1960s, for whom he became something of a folk hero. The scornful attacks of the early 1950s, and especially tales of a threatened textbook boycott against his publisher, Macmillan, helped build up an image of a scientific martyr, a modern-day Galileo alternately jeered and ignored by the entrenched scientific establishment.

Thus, by 1974, several of us agreed that a forum should be provided for Velikovsky to meet his scientific critics, and for the scientists to put on the record a clear statement of their objections. The actual encounter, at a meeting of the American Association for the Advancement of Science in San Francisco, proved to be a memorable non-meeting of minds, with a highly polarized audience full of partisans unlikely to be swayed by arguments or counter-arguments from either opposing camp. Scientists who had advocated silence on the matter went away with an "I told you so" attitude. Nevertheless, this second wave of criticism was harder for Velikovsky's supporters to cope with, and Velikovsky felt particularly stung by the witty and articulate attack made by Carl Sagan. In colourful terms, Sagan described such things as the "fly ablation problem", that is, the difficulty of flies originating on the Venus–comet in entering our atmosphere just in time to cause the pharonic plague of pests.

Today, although Velikovsky's catastrophism is rapidly being forgotten, the fierce controversy that swirled for three decades can still teach us something about the nature of science and trans-scientific challenges. It is such questions that Henry H. Bauer, Dean of the College of Arts and Sciences at the Virginia Polytechnic Institute, has explored. A personal and somewhat idiosyncratic account, *Beyond Velikovsky* contains material to infuriate or at least exasperate everybody. Nevertheless, it is the most balanced and informative analysis yet to emerge from the whole affair.

Bauer argues that science does not find absolute truth, but only a high degree of probability. This prevents scientists from claiming that any particular sequence (such as Velikovsky's) is impossible, only that it is staggeringly unlikely. However, Velikovsky never claimed that his scenario was probable, only that it happened. Hence, counter-arguments that it was improbable completely missed the point. Velikovsky was staking his claims on an entirely different turf — "trans-scientific" in Bauer's terminology — and so the normal type of scientific argument lost its force against Velikovsky and his supporters. In their frustration, scientists were frequently reduced to appeals to authority (their own, of course), which went directly counter to their own claims of how science worked.

Unreal Science

SIR,—As a qualified and practising scientist I wish to dissociate myself from your editorial of April 12. You allude to Geller and Velikovsky with terms like "nonsenses", "beliefs beyond science", and "pseudo-scientific ideas", and contrast these with "real science" and "science based on conventional ideas about the way a scientific investigation should proceed", and you declare that "scientists want to fight this distressing drift from the scientific way of thinking".

History is littered with ideas shown to be false by people bold enough to question their contemporary conventional science, often in the face of personal ridicule and even persecution.

Presumably you class Einstein's

Passions run high — a letter in Nature, *28 June 1974, in response to an editorial on Velikovsky.*

Velikovsky, too, was frustrated by the resistance from the scientific community, so he consulted his neighbour at Princeton, Albert Einstein, about the status of his theory. Einstein assured him that it would be better if the theory could *predict* something. Thereafter Velikovsky searched his writings and came up with a series of "advance claims" that he had made, ranging from high temperatures on Venus to radio noise from Jupiter. Unfortunately, Einstein had not made it clear to him (and thus to Velikovsky's followers) that predictions have to be made for the right sorts of reasons to be persuasive. The principles must fit with the coherence of scientific understanding, and they should not be single *ad hoc* instances incapable of supporting further, related predictions.

Bauer analyses both Velikovsky's physical reasoning and his advance claims, and both are found wanting. Although Velikovsky's scenario cannot be denied outright, it is relatively easy to show that his understanding of physical principles was hopelessly faulty. "There is rarely a certain way of identifying a crank", Bauer cautiously asserts, and only after 150 pages does he label Velikovsky one in the sense of a person "enthusiastically possessed by a particular crotchet or hobby". But in a devastating chapter entitled "A Nontechnical Case against Velikovsky" he leaves no doubt that the enthusiastic Dr Velikovsky was also a crank in the more pejorative sense of the word.

Nor do Velikovsky's opponents escape Bauer's criticism. "In retrospect", he writes, "it seems clear that Velikovsky's critics did not grasp the magnitude — or perhaps even the nature — of the task of discrediting Velikovsky in the eyes of the public at large". Bauer charges them with errors of commission — arguing *ex cathedra*, with ridicule, *ad hominem* — as well as with errors of omission. In the latter category is, primarily, the failure to capitalize on the unoriginal character of Velikovsky's scheme.

There is, however, one logical path that, curiously enough, Bauer has not explored. Although science cannot prove that a Velikovskian scenario is impossible, it might well prove that it did not happen. At the San Francisco confrontation, Peter Huber provided evidence from Babylonian records that Venus in 1600 BC behaved just as it did in the centuries immediately before our own era. I remarked at the time that if Huber was right (as I certainly believe), Velikovsky's scenario was finished. Velikovsky tossed one of his *ad hominem* barbs at Huber, labelling him a self-confessed amateur in Babylonian. Huber, who is one of the world's leading statisticians and a redoubtable cuneiformist on the side, quickly proved on the stage how ignorant Velikovsky himself was of cuneiform languages. The Velikovskyites were naturally reluctant to admit defeat by a single stroke, so they have since worked hard to discredit the Babylonian data,

New Titles from Chapman and Hall

Electron Beam Analysis of Materials

M H LORETTO

The microstructure of materials controls many of their important physical, mechanical and electrical properties. In order to understand and control these properties it is essential to assess microstructure at a resolution down to the atomic level.

This book describes in detail the many electron beam techniques developed for the assessment of microstructure, and provides an overview for student and practitioner alike.

Announcing a change of publishers

TROPICAL PEST MANAGEMENT

An international quarterly on pre- and post-harvest pest management. Founded by The Tropical Development and Research Institute, London, and now published by Taylor & Francis, international scientific and technical publishers

Editor: Dr P. T. Haskell, Cleppa Park Research Station, University College, Cardiff CF1 1XL, UK

Editorial Executive Panel: Professor G. Asprey, Dr G. T. Jefferson, Mr P. Humphreys, Dr M. F. Claridge, Dr T. Gabriel (Book Reviews Editor); based at the University College, Cardiff

Tropical Pest Management is established as a leading international journal. Taylor & Francis will maintain close links with the founding institution, TDRI, and with the introduction of new Editors the journal will broaden its scope to include pre- and post-harvest pest management in the Tropics and Subtropics as well as the wider aspects of farming systems, rural development, extension techniques, human resources and public health. Each issue contains a news and information section to keep readers up-to-date with the recent developments in tropical pest management.

Tropical Pest Management is essential reading for anyone practically involved in pest management: farmers, rural development workers, pest control officers, agrochemical and farm equipment manufacturers.

Subscription rate 1985 Vol. 31

which were unavoidably contaminated with copyists' errors (and hence Huber's statistical approach). Ambiguous data often characterize the cutting edge of science, and discussion of the point would have added another dimension to Bauer's analysis.

With the decline of interest in Velikovsky, another, surprisingly similar, challenge is facing the scientific establishment: so-called "Creation Science" whose extreme form calls for a 6,000-year-old Earth geologically shaped by Noah's flood. Fossil footprints of a giant humanoid beside indisputably genuine dinosaur prints in the rocks of the Paluxy Creek, Texas, are taken quite seriously by many of these fundamentalist, Biblically-literalistic people. Bauer's closing chapters on "Means of Persuasion" and "Some Realities about Science" offer sound advice about pitfalls to be avoided in these "trans-scientific" debates, where probabilities, values and desirability are at stake. How successfully his analysis can be brought to bear upon this new challenge remains to be seen. But arguing that the creationist ideas have been heard before does not seem to be a cogent strategy. Rather, we must argue that even if science is "never completely final, always subject to question and doubt" (as Einstein put it), nevertheless it is of a piece, not easily shredded, and the process of building this coherent tapestry is what science is all about.

Beyond Velikovsky is awkwardly repetitive, not as complete as it might appear at first glance and in its own way rather too polemical. Its system of references, numbered but unattributed in the text itself, is seriously distracting. Nevertheless, the account is detailed, thought provoking, and the best yet written on a bizarre episode that continues to smoulder in the annals of science. □

Continental epic

Robert M. Hazen

Landprints: On the Magnificent American Landscape.
By Walter Sullivan.
Times Books, New York: 1984. Pp.384. $22.50.

"THERE is no epic tale to compare with the account of how the North American continent came to be." So begins *Landprints*, one of the finest popular earth science books to appear in decades. In this recounting of the 3,500-million-year evolution of the mountains and valleys, rivers and deserts of North America, Walter Sullivan, the science editor of the *New York Times*, has achieved a masterly blend of geomorphology, historical geology, geophysics, structural geology, palaeontology and geodynamics.

The book consists of 37 short, self-contained essays on the principal features of the American landscape. Inspiration for this geological feast came from the author's frequent transcontinental flights; as Sullivan observes, many of the continent's landforms are best viewed from the air. The first two dozen chapters, therefore, focus on striking geomorphological features — parallel ridge systems, meandering rivers, volcanic craters and cones. The White Mountains, Wyoming basins, Hawaiian Islands and the Grenville Province are among the many areas which are examined first in terms of their distinctive aerial appearance, but then also from the standpoint of their underlying geological structure and history. In this way Sullivan gradually introduces current views on plate tectonics, continental subduction, and the regional folding and faulting that are associated with mountain building.

The last third of the book emphasizes the dramatic alterations of the Earth's surface imposed by man. Farms and mines, cities and suburbia have all left their distinctive imprint on North America, and Sullivan discusses both their geological and environmental significance. He explains why East Coast cities grew up along a former continental shelf margin (the "fall line"); he shows how rock erosion influences soil chemistry, which in turn controls the predominant crops of American farms. From aerial observations of the distinctive patterns caused by centre-pivot irrigation, hydroelectric dams and strip mining, Sullivan proceeds finally to consider the possible consequences of man's actions on his environment.

Landprints is graced by a magnificent collection of photographs and other illustrations. Aerial and Landsat photos — more than 150 of them — display the variety and splendour of North American topography, both natural and man-made. Views of ancient craters, barrier islands, dune fields and the crazy-quilt of America's farms, photographs of road-cuts, regional maps and schematic diagrams of geological processes, all enrich the presentation.

This is a beautifully produced book, too, with clear typography, a felicitous layout and sturdy binding. The writing is stylish and informative, in the best tradition of popular scientific literature; Sullivan brings to his subject an infectious sense of wonder and enthusiasm — he entertains as he teaches. Anyone interested in science, particularly those who travel frequently by air, will be well rewarded in reading this continental epic. □

Earth science in a fabulous place

Peter J. Smith

Atlantis in the Light of Modern Research.
By Zdeněk Kukal.
Elsevier: 1984. Pp.224. $57.75, Dfl. 150.

How the childhood memories come flooding back! The idea of Atlantis was introduced early into my genteel upbringing, presumably as a spur to the imagination much as a spot of breakfast is supposed to set the digestive processes rolling. Plato's lost world beat its competitor, Little Noddy, hands down, losing its status as prime imaginative wonder of the world only under the impact of the higher Blytonian *Island of Adventure* and, later, the more robust yarns of Percy F. Westerman and Arthur Conan Doyle. Besides, in the black-and-white world of the teens, fiction was fiction and fact was fact, but fiction masquerading as fact (as, by then, we all knew Atlantis to be) was strictly for the gullible. When we became adults we put away childish things, did we not?

But no, actually, some of us didn't. N.F. Zhirov of the Soviet Union, reputedly the world's most devoted "atlantologist", is even now engaged in a review of all of the estimated 3,600 works on Atlantis published to date. A Dr E. Sykes is said to edit *Atlantean Research*, a periodical containing such gems as "Atlantis, land of giants" and "Atlantian script". Pierre Benoit wrote the most famous of all novels about the place. And Zdeněk Kukal, a member of the Geological Survey of Czechoslovakia and author of more than 200 legitimate papers and books on matters geological, now presents the results of 20 years' study of the scientific aspects of Atlantis.

What these four representatives of a much larger motley demonstrate, of course, is that Atlantis has a number of distinct faces. There is Atlantis as jumping-off point for harmless fantasy, which sees Plato as an early science-fiction writer. To the extent that fantasy is therapeutic, here surely lies Atlantis's most abiding contribution to the welfare of the human race, although Kukal ignores all that because it is not science. Then there is Atlantis as advanced civilization. But is it likely that there was really, as Plato claimed, a ten-million-strong community that could write, work metals and breed domestic animals many millennia before the time for which there is evidence of such things elsewhere? Kukal thinks not.

That leaves Atlantis as a physical, geographical and geological entity, albeit one that, according to Plato, suffered "violent earthquakes and floods, and in a single day and night of misfortune . . . disappeared in the depth of the sea" about 11,500 years ago. Not that Plato's sea should be taken too literally, it seems, for of the 40-odd possible locations of Atlantis given in the literature (ranging from the United States to the Black Sea and from Iceland to Zimbabwe) almost half are on land. As far as the ocean floor is concerned, however, Kukal has to admit that echo sounding, deep-sea drilling, dredge and grab sampling, underwater photography and bathymetric descents have revealed not one whiff of Plato's place.

From this discouraging beginning Kukal goes on to assess in some detail whether we could just have missed the sunken state (possibly), whether city walls and metal artefacts could have survived 11,500 years of submergence anyway (highly unlikely), whether Atlantis could have been any of the fictitious islands shown on early maps (no), whether it could have been any of today's real islands (geologically impossible) and whether there are any areas of subsidence in the Atlantic or Mediterranean which might qualify (not really). He then considers whether the supposed Atlantis could have been destroyed by earthquake or tsunami (theoretically possible), storm flood (probably not), volcanic eruption (yes), slow tectonic movement (no), cosmic impact (no evidence) or rising sea level (yes, but not "in a single day and night").

There is something faintly ludicrous about all this; it is a bit like mounting a scientific search for the invisible man simply because H.G. Wells happened to write about one. On the other hand, in describing the search for Atlantis, Kukal does manage to impart a lot of earth science — the geology of islands and oceans, the nature of glaciation, the role of sea-level changes, the processes of weathering and much else besides. The means may not justify the ends, but they make a fascinating story all the same.

I began the book with an inclination to mock, but ended up with a grudging respect for Kukal. He has produced a fine and objective refutation of a "theory" that may be inherently ridiculous but is nevertheless important because it has duped thousands of people over the centuries. Atlantis was a deliberate fiction and a particularly successful one at that, for it still attracts attention after 2,500 years. The advanced civilization of Atlantis was Plato's Utopia; its physical and political structure was the best Plato could envisage; and its destruction was by processes known to him. There can be no other conclusion, although one almost wishes that after 20 years of work Kukal could have proved otherwise. Of course, the only people to accept his verdict will be those who believed it in the first place. Those who don't never will. All will continue much as if Kukal had never been. □

Swimming through the cell

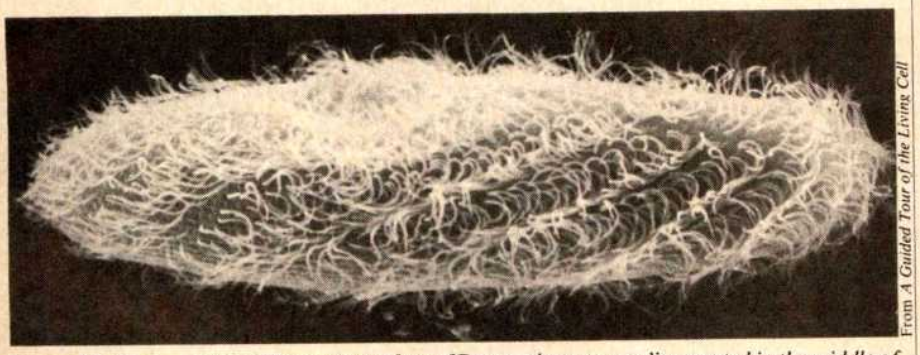
Tim Hunt

A Guided Tour of the Living Cell, Vols 1 and 2.
By Christian de Duve.
W.H. Freeman:1985. Pp.423. $55.95, £39.90 per set.

Here is the latest biological work from W.H. Freeman in the Scientific American Library. It spans two volumes, but is a seamless whole and the two jackets are identical except for the words "One" and "Two". Like its predecessors in the series, *A Guided Tour of the Living Cell* is beautifully produced and written, and its author uniquely qualified to show us around. Christian de Duve is one of the great pioneers of cell biology; together with Albert Claude and George Palade, he was justly awarded the Nobel Prize in medicine in 1974 for his "discoveries concerning the structural and functional organization of the cell".

You may remember a film called *The Incredible Voyage* in which heroic brain surgeons operated on the patient by shrinking themselves down to a microscopic size and making their way to the site of the damage in a tiny submarine which was injected into a vein. The operation successfully completed, they escaped by means of the tear duct after many a frightening adventure, the worst an ugly encounter with a macrophage. In his books de Duve shrinks the reader even further, to the point where the very organelles of the cell are as huge caverns to the observer. What is more, we are protected only by a diving suit (a magic suit, it's true, made of the material that coats the leprosy bacillus) as we swim around the cell with the Master as our guide. The idea sounds perilously twee, and when the introduction reveals that these are the books of a series of childrens' Christmas lectures, the heart sinks even further. However, my initial suspicion wore off within a few pages and the idea works brilliantly well — they must have been fabulous lectures!

Not surprisingly, de Duve is at his best describing the workings of the membrane systems of the cell, and particularly in describing lysosomes. As he says "understanding, not description, is the true purpose of scientific exploration", and in this chapter understanding comes as if by enchantment. We are lucky in other ways besides. de Duve's language is plain, his images concrete and familiar, and the text is strewn with wise words. Several times I found myself warming, seeing things said that do not often appear in books of any kind, let alone relatively elementary texts. Other agreeable features of the general style are de Duve's readiness to admit ignorance and to point out



puzzles, and his unfailing grace in explaining the (usually classical) origins of terms.

However, the *Incredible Voyage* approach has its limitations, most evident in the biochemical parts of the books. Very few people really enjoy biochemistry, probably because of its rather abstract nature. It's a subject that's fun to *do*, but not so much fun to read about. de Duve adopts two "outlandish terms" (sic) the "Janus Intermediate" and the "Oxphos Unit". The Janus Intermediate "arises from a nucleophilic attack by an oxygen containing building block (X–OH or X–O$^-$) on ATP or some related energy-rich molecule, which we will designate provisionally as A–B, in order to avoid going into complex chemistry"; later we learn that "Janus...is Mercury and Aquarius all in one". You see? The excellent colour graphics make it more palatable, but whereas other parts of the book repeatedly opened my eyes, I found the biochemistry and bioenergetics not only unilluminating but even baffling in places. I never really did get the Oxphos unit.

In his introduction, de Duve is apologetic about his approach to biochemistry, as if he knew he was taking a bit of a risk and hadn't quite got it the way he would have liked. It would be interesting to know how a non-biochemical reader would fare. It *is* very difficult to know how to deal with biochemistry in a modern account of the cell. Whether you are a strict cell biologist or a full-blooded clone-and-sequence molecular man, enzymes and the reactions they catalyse keep on creeping into consciousness both as tools (don't forget to add the ATP to your ligations) and as the very objects of study; what does the recently discovered "homeoprotein" actually *do*? Yet we shy from the gory biochemical details. Why should this be so? Is it because of a lingering distaste for the blood and guts origin of the subject? Or because our algebra stopped short of the Michaelis–Menten equation, which we were led to think lay at the heart of the subject? Or because the chemical formulae were too big to remember, and the pathways too complex to comprehend except by rote the night before the exam? Or because explanations too often stopped before they really made sense? This is a topic that needs exploring at greater length, precisely because it seems to cause such trouble. de Duve includes some appendices dealing with biochemistry and bioenergetics which would have been helpful in the body of the text, but they are at the end of the second volume so consulting them is not encouraged. Probably you either have to grasp the nettle and give the full treatment, or leave it out altogether.

In the nucleus we are for the most part in conceptual country which de Duve understands very well, but doesn't know like he knows his organelles. de Duve is not alone in speaking of "the nucleus" as standing for almost all of molecular biology; this is common parlance among cell biologists. Yet molecular biology as I understand it has very little to do with the nucleus as such. It stands for a much more highly conceptualized scheme of things that transcends (for the time being) its cellular location. Actually, we don't even understand clearly why there is such a thing as a nucleus; bacteria get along without it and *Saccharomyces cerevisiae* commits mitosis without ever losing its nuclear membrane. Curiously, this kind of issue is not considered here. There is discussion of what the nuclear membrane lets in and out, of nuclear pores and how little we understand of how they work, of how the membrane vesiculates prior to mitosis (we have to wait for this to happen to get out!), but not of why it's there in the first place. (Alberts *et al.* in *Molecular Biology of the Cell* suggest that it's to keep protein synthesis out, thus allowing splicing to occur.) I was disappointed by de Duve's silence on the matter, for elsewhere he almost always has something interesting to say.

These two volumes are an extravagant buy for the individual, but they must go into my college library and I would advise intending biologists who have not done the subject at school to try and get hold of them before they go up to university. For, despite their deficiencies, the books are a splendid introduction to cell biology, and the first hundred pages could and probably should be read with profit and enjoyment by every biologist. □

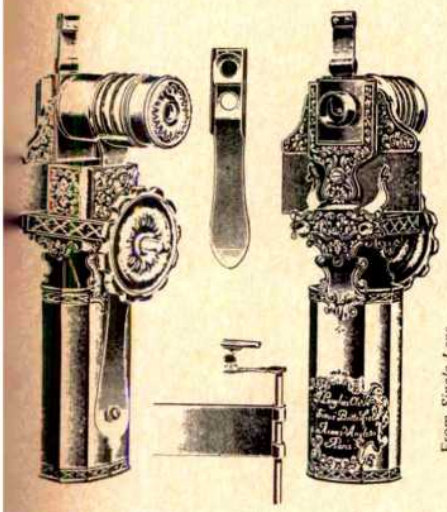
Nature magnified

Peter Evennett

Single Lens: The Story of the Simple Microscope.
By Brian J. Ford.
Heinemann/Harper & Row: 1985.
Pp. 182. £10.95, $14.95.

THE simple microscope, one whose optical system consists of a single lens, operating in the manner of a magnifying glass, has a distinguished place in history and quite remarkable capabilities, little known to the general scientist. The origins of its use are obscure, but by far the best known early work is that of Antony van Leeuwenhoek of Delft, communicated in the form of a series of letters to the Royal Society from 1673 until shortly before his death in 1723. One third of Brian Ford's book is devoted to Leeuwenhoek, his microscopes and specimens.

Using single-lens microscopes, Leeuwenhoek was the first to observe Protozoa, bacteria and spermatozoa: truly microscopic objects. In contrast Robert Hooke, Leeuwenhoek's contemporary working in London who published *Micrographia* in 1665, used a compound microscope (consisting of two lenses, objective and eyepiece). Both men's observations were excellent within their own limits, but while Hooke's work — on relatively large objects such as the flea or the sting of the nettle, for example — extended existing knowledge only slightly (though illustrating it most beautifully), Leeuwenhoek broke entirely new ground. The reason for this was principally his choice of microscope: lens design was then in its infancy and, to put it crudely, one poor lens gave better results than two poor lenses.



In addition to his letters, Leeuwenhoek also sent specimens, in small paper packets pasted to the letters; many of these survive in the archives of the Royal Society. In researching this book, Ford took some of the specimens to Utrecht and photographed them with an original microscope, demonstrating to those of us unlikely ever to lay hands on one the nature and quality of the image of a Leeuwenhoek microscope. A study of the surviving instruments shows that they were capable of resolving features as small as one micrometre, with a magnification of several hundred times — a performance as good as that of many school microscopes of today; indeed, for 300 years single-lens microscopes have been

New in paperback

- The ninth edition of *Henderson's Dictionary of Biological Terms*, revised by Sandra Holmes. Publisher is Longman, price £4.50.
- *The Ecology of Animal Movement*, edited by Ian R. Swingland and Paul J. Greenwood. Publisher is Oxford University Press, price £12.50.

apable of revealing most of the significant tructures that can be resolved by a modern ight microscope.

After Hooke and Leeuwenhoek, the ompound microscope increased in opularity as a "drawing-room" instrunent, presumably because of its impressive ppearance and greater ease of use; Ford lescribes the progress of the simple nicroscope in the form of the cheap flea-glass, the more versatile compass microcope, and the screw-barrel and later lesigns. A simple microscope is little more

From *Single Lens*

Art of the instrument-maker — an elaborately decorated simple microscope produced in Paris, c.1720.

han a device to hold a specimen and a lens n suitable relationship one to the other, its lesign naturally influenced by the nature of the specimen to be examined. Around he middle of the eighteenth century the 'aquatic" microscope was designed, arranged to stand on a table, with a movable ens to enable it to scan sensitive creatures uch as *Hydra* without disturbance. Linnaeus owned one of these, and a similar hough superior example was used by the Scottish botanist Robert Brown in 1827 when he discovered "active molecules" now known as Brownian movement), and a few years later when he described the nucleus and cytoplasmic streaming in the plant cell. Darwin took a microscope of this kind on the *Beagle* expedition in 1831, on Brown's advice, and wrote of his purchase of another in 1848. An essentially similar nstrument is still available as a "dissecting nicroscope".

The simple microscope has not been well documented previously. Brian Ford's book s a clearly written non-technical account of the instruments, the lenses, their performance and use, illustrated with historical necdotes, quotations and drawings, and with a useful bibliography. It will interest anyone who uses a microscope and many others besides. □

Peter Evennett is a Lecturer in the Department of Pure and Applied Zoology, University of Leeds, and Editor of the Proceedings of the Royal Microscopical Society.

Psychiatry: beyond analysis

Anthony W. Clare

The Broken Brain: The Biological Revolution in Psychiatry.
By Nancy C. Andreasen.
Harper & Row: 1985. Pp.278. $16.95, £12.95.

A COMMONLY expressed dictum, usually by psychiatrists, is that there has been a revolution in psychiatry. Back in 1966, the late Sir Aubrey Lewis of the Maudsley Hospital wryly noted the common and invigorating habit of psychiatrists to rejoice "that they live in an age of rapid and impressive advance". Advances there have surely been but whether any of them warrants the description "revolutionary" is highly questionable.

Just after the Second World War, the new antipsychotic phenothiazines and the tricyclic antidepressants were hailed by psychiatrists such as William Sargant in Britain and Nathan Kline in the United States as the harbingers of a revolution in physical treatment which would empty the mental hospitals and re-establish psychiatry within the mainstream of general medicine. Even before the introduction of these drugs, however, the mental hospital population on both sides of the Atlantic had begun to fall and this trend too was acclaimed as reflecting a revolution in care. Much of its momentum derived from the realization that institutionalization of the chronic mentally ill could in many instances worsen the condition and add substantial secondary impairment. A vigorous new emphasis within psychiatry was born, social psychiatry, whose enthusiastic adherents emphasized the importance of energetic rehabilitation and rapid reintegration of the mentally ill within the general community. In the United States, the presidential involvement of John F. Kennedy gave the movement a particular momentum such that over a quarter of a century the mental hospital population has fallen by nearly 75 per cent (compared with the more pedestrian British decline of 25 per cent) and a whole chain of community mental health centres has been deployed across the continent.

The mid-1960s, a turbulent time within as well as outside psychiatry, witnessed the flowering and then the demise of arguably the most revolutionary idea of all, namely that mental illness does not actually exist but is a myth, a metaphor or merely an obfuscating and remarkably sticky label. The mentally ill were variously portrayed as outsiders, deviants and voyagers on a perilous journey of self-discovery and transcendentalism. Around the same time, the more prosaic yet more enduring advances in behavioural theory in turn yielded a series of promising techniques of behavioural treatment, including desensitization, operant conditioning and flooding, offering hope to sufferers of the most intractable of neurotic conditions such as phobic anxiety and obsessive compulsive disorder.

If one uses the term "revolution" in the sense of the undermining and overthrow of the established order, then none of these developments seriously threatened psychiatric orthodoxy. Psychotropic drugs, psychiatric rehabilitation, the development of community-based facilities, the application of behavioural techniques — each has been comfortably absorbed within the general mainstream of psychiatry. In the process, the original enthusiasm has been tempered by time and by bitter political experience. In the case of the much-vaunted community mental health centre programme, for example, professionals, politicians and the public appear deeply divided not about whether it was a good or a bad idea but about who precisely is responsible for the disaster that it has turned out to be. Its critics blame the haste, the ill-conceived design which has led to the warehousing of large numbers of chronically ill psychiatric patients in squalid and anti-therapeutic conditions within a community which clearly does not care, and the failure of its advocates to acknowledge the degree of disability manifested by those who are most seriously mentally ill. Its supporters attack the failure of Federal government to honour funding pledges made by its predecessors and the marked ideological shift in the way that Washington regards the concept of community welfare.

Unabashed, American psychiatrists are now acclaiming a new revolution. The author of *The Broken Brain*, a book revealingly subtitled *The Biological Revolution in Psychiatry*, is moved to declare with the enthusiasm of one who has witnessed the fall of some psychiatric Bastille, that "Psychiatry, like the prodigal son, has returned home to its place as a specialty within the field of medicine". For Nancy Andreasen, Professor of Psychiatry at Iowa College of Medicine, psychiatry is becoming increasingly scientific and biological in its orientation and medical science is now convinced that the serious forms of mental illness, such as schizophrenia and manic-depression, are due mainly to abnormalities in brain structure and chemistry.

British readers, familiar with the relatively close relationship between psychiatry and general medicine in this part of the world, may wonder what all the fuss is about and where the American prodigal son has been all these years. Yet the argument that in the United States at least there may indeed be a significant shift in psychiatric thinking, if not a revolution, does merit closer examination. There was a time, less than 25 years ago in fact, when it was difficult if not impossible to become the chairman of an American department of psychiatry unless one had undergone psychoanalytical train-

ELSEVIER'S INVERTEBRATE FOSSILS CHART

P. LOF

Fossil collectors, students and professional palaeontologists, will be delighted to learn that Elsevier's new wall chart — available now — is devoted to invertebrate fossils. Reviewers have always commented on the extremely high reproduction quality of the photographs in Elsevier's wall charts and tables, and this latest one is no exception. The chart presents:

- ★ 156 full colour photographs
- ★ all major groups of invertebrate fossils
- ★ morphological explanations
- ★ up-to-date taxonomy down to the level of order
- ★ biostratigraphy down to the level of epoch
- ★ summaries of diagnostic characteristics
- ★ full indexes and references

Undergraduate students of geology have to have a basic knowledge of invertebrate fossils. This poster will provide them with all the information they need — at a glance. It is a handy, informative and decorative reference for both amateur collectors and professionals alike.

THE NORTHWEST EUROPEAN POLLEN FLORA, IV

W. PUNT, *Utrecht, The Netherlands and* **G.C.S. CLARKE,** *London, U.K. (editors)*

Published under the auspices of the Royal Botanical Society of the Netherlands

(Reprinted from Review of Palaeobotany and Palynology, Vol 42)

The fourth in a series of books which has been described as "the definitive work on the pollen of northwest Europe . . . most valuable and useful.". All the volumes are abundantly illustrated with photographs for easy identification of pollen types. Keys are provided to the pollen types within each family as well as comprehensive descriptions, plus references to the pertinent literature. This volume covers families. It maintains the high standard set by its predecessors and will without doubt prove invaluable to all serious palynologists.

CONTENTS: Araliaceae (H.A M. van Helvoort and W. Punt). Berberidaceae (S. Blackmore and G.L.A. Heath). Cannabaceae, Moraceae and Urticaceae (W. Punt and M. Malotaux). Compositae - Lactuceae (S Blackmore). Fagaceae (F. van Benthem, G.C.S. Clarke and W. Punt). Hippocastanaceae (G.L.A. Heath). Menyanthaceae (S. Blackmore and G.L.A. Heath). Plumbaginaceae (S.C. Turner and S. Blackmore). Umbelliferae (W. Punt). Index.

QUATERNARY DATING METHODS

W.C. MAHANEY, *York University, Downsview, Ont , Canada (editor)*

(Developments in Palaeontology and Stratigraphy, 7)

This book contains the proceedings of a symposium held at York University in May 1981. The papers cover absolute, relative and multiple dating methods, and have been written by specialists from a number of different earth sciences disciplines — their common interest being the dating of geological materials within the Quaternary.

Papers on absolute dating methods discuss radiocarbon, uranium-series, potassium argon, $^{40}Ar/^{39}Ar$, paleomagnetic, obsidian hydration, thermoluminescence, amino acid racemization, tree rings, and lichenometric techniques. Those on relative dating include discussions on various geomorphic relative age indicators such as drainage density changes, hypsometric integrals, bifurcation ratios, stream junction angles, spur morphology, hillslope geometry, and till sheet characteristics. The papers on multiple dating cite examples from the Rocky Mountains, Australia, Lake Agassiz Basin, and the Southern Andes. Also included is the panel discussion which reviews and assesses the information presented, and a field trip guide which discusses the sequences of Wisconian tills and interlayered lacustrine and fluvial sediments.

CLAY MINERALS

A Physico-Chemical Explanation of Their Occurrence

B. VELDE, *Ecole Normale Supérieure, Laboratoire de Géologie, Paris, France*

(Developments in Sedimentology, 40)

This is the latest book by Bruce Velde, whose earlier book "Clays and Clay Minerals in Natural and Synthetic Systems" (1977) was "an excellent attack on clay mineral petrology . . informative, and stimulating. Not only clay-mineral scientists but petrologists in general must read this first book on clay mineral petrology." (Earth Science Reviews). The new book describes clay mineral occurrence in terms of the physical and chemical forces which influence it. The author has thoroughly reviewed the relevant literature for the last 25 years and the data and analyses obtained will be extremely useful to those involved in deep sea research, mining geology, petroleum geology, agronomy and civil engineering.

CONTENTS: I. Introduction. Choice of Information. Clay Mineral Names and Structure. Chemical Systems. Stability and Meta-stability. Stability and Reaction Rate. Geological Environments. Chemical Coordinates for Phyllosilicates Assemblages. Summary. II. Minerals and Mineral Groups. Silica. Kaolinite, Pyrophyllite, Gibbsite and Talc. Potassic Micas and Mica-like Minerals. Smectites. Chlorites. Zeolites. Sepiolite-Palygorskite. III General Phase Diagrams for Some Clay Mineral Assemblages. Introduction. General Systems. Weathering. Hydrothermal Alteration. Deep Sea Basalt Alteration. Mixed Layered Minerals in Sequences of Buried Rocks (P-T Space). Conclusions. References. Index.

New books

Developmental Biology

S.F. Gilbert. May 1985.
680 pages, 567 illustrations. About £34.00

This new approach to developmental biology provides a comprehensive introduction to molecular and cellular concepts of development while placing them in the framework of the developing embryo. Well organized and clearly written, the book puts recent advances in developmental biology into a coherent and conceptual order.

While the book is designed for juniors and seniors, it does not assume more knowledge of biology than that provided by good introductory biology courses. Thorough and up-to-date, this new textbook effectively conveys the excitement and creativity now taking place in the rapidly growing field of developmental biology.

GENE EXPRESSION IN MUSCLE

edited by **Richard C. Strohman** and **Stewart Wolf**

Targeted toward the identification of the pathogenic mechanism of Duchenne dystrophy, this interdisciplinary volume synthesizes and interprets the latest data on gene expression during muscle development with a focus on changes in the molecular structure of contractile proteins in their various stages of maturation Of special interest to neuropathologists, geneticists, and cellular and developmental biologists. Volume 182 in Advances in Experimental Medicine and Biology

ing and a personal analysis. Up to quite recently, most major medical schools accepted psychoanalytically orientated psychotherapy as the foundation of psychiatric theory and practice, and in a number of them — most notably New York Medical College, Columbia, Pittsburgh, Tulane, Western Reserve and North Carolina — actual postgraduate psychoanalytical institutes were established. Not merely were most departmental heads psychoanalysts, so were most of the members of their departments, their psychiatric residents, their own personal psychotherapists, their wives and many of their government site visitors. In psychosomatic medicine, child and adolescent psychiatry, the psychotherapy of the neuroses, social casework, individual and group therapy, the impact and influence of psychoanalytic theory and practice were enormous.

Yet even at its zenith psychoanalysis was under fire. In 1959, two research psychiatrists, J. MacIver and F. Redlich, writing in the *Journal of the American Medical Association*, critically observed that "the hard truth is that we are expending enormous effort, time and money to train a highly specialized group of experts who will devote the bulk of their professional careers to a small group of highly selected patients". Several years later, a distinguished biologist, Seymour Kety, was appointed to head the psychiatric department at Johns Hopkins. Together with David Rosenthal and Paul Wender, he embarked on a programme of research which was to cast light on the chemical nature of synaptic transmission, develop a number of potent drugs capable of specific actions against many of the symptoms of severe mental illness, and provide new and substantial evidence of genetic factors operating in the aetiology of the major psychoses. Indeed one prominent psychoanalyst spoke prophetically at the time of Kety's appointment that it was calculated "to drive another nail into the coffin of analysis".

Despite these and related biological developments, however, American psychiatry clung on to its heavily analytical reputation until the past few years when suddenly it appears to be discarding it rapidly. Professor Andreasen expresses the widely held view that it is the exciting developments in neuroanatomy, neurochemistry, neuropathology, neuropharmacology, genetics and behavioural neurology which have not just undermined the preeminence of psychoanalysis but significantly eroded it. Her book, in a highly readable if occasionally simplistic fashion, emphasizes the manner in which such explanatory ideas as the catecholamine theory of depression and the dopamine theory of schizophrenia, while partial, flawed and even contradictory, have in their own way reminded a whole new generation of young psychiatrists of the possibilities and challenges inherent in the biological approach. Hemispheric localization, limbic system function, GABA, positron-emission tomographic scanning, the dexamethasone suppression test, benzodiazepine receptors — the topics included and discussed, while in no way adding up to a coherent and plausible theory of brain dysfunction in psychiatric disease, illustrate the potential for research and the bewildering number of growing points.

In her enthusiasm for these developments, Andreasen, in common with many of the new biologists, ignores the lessons of recent history. The reverses suffered in turn by psychoanalysis and social psychiatry, each originally hailed as true revolutionary breakthroughs in the way we understand and treat mental illness, should not be ignored. If psychiatry in the United States has a fault it surely is its tendency to suffer from what Gore Vidal, in another capacity, has termed the peculiarly American affliction of "historical amnesia". At times, Professor Andreasen acknowledges the limitation of reducing all psychopathology to the level of abnormally firing neurones, all psychiatric disorder to the level of brain disease. On other occasions, her zeal gets the better of her and she commits precisely that error. Yet psychiatry has been here before, just over a century ago, but one will look in vain in the index for the names of Griesinger and Maudsley, Westphal and Meynert, men who also nourished the hope that one day severe psychopathology might be reduced to a matter of disturbed cerebral function.

The resurgence of biological enthusiasm doubtless owes much to the new and exciting plethora of scientific tools and techniques applicable to unravelling the complexity of brain function. It owes much too to the realization that psychoanalytic theory is sterile and psychoanalytic treatment is ineffective. But before participating in a single-minded and headlong rush to the brain, enthusiasts would do well to heed Kety's reminder that the language that we speak, the principles we value, the thoughts we think, the decisions that motivate our daily actions are to a greater extent a reflection of what we have learned than the result of how we are constituted. "The differences among us in respect of these qualities", he has recently written, "are not to be found in the structure or chemical composition of our brains but lie largely within the scope of the psychological and social sciences". If this is ignored, then crude biological reductionism is the result and the possibility that psychiatry might act as the bridge in medicine between the biological sciences on the one hand and the psychological and social sciences on the other hand evaporates. That is hardly a development worthy to be considered revolutionary. □

Sowing the seeds of awareness

David Streeter

Green Inheritance.
By Anthony Huxley.
Collins–Harvill/Anchor–Doubleday: 1985. Pp. 193. £9.95, $19.95.
Our Green and Living World: The Wisdom to Save It.
By Edward S. Ayensu, Vernon H. Heywood, Grenville L. Lucas and Robert A. Defilipps.
Cambridge University Press/Smithsonian Institution Press: 1984. Pp. 255. £12.95, $24.95.
In the Rain Forest.
By Catherine Caufield.
Heinemann/Knopf: 1985. Pp. 304. £10.95, $16.96.

ONE of the most striking features of current radio and television, in Britain at least, is the number of natural history programmes that are finding their way into the schedules. Radio 4 alone, for example, is currently putting out five such programmes a week. Until recently, however, wildlife was considered to consist wholly of animals; even in David Attenborough's celebrated television series *Life on Earth*, plants made a significant appearance in only one out of the thirteen parts.

David Bellamy's early programmes have done much to redress the balance and coincided with the emergence of a higher profile conservation movement drawing attention to, among other issues, the attrition of the tropical rain forests. The established conservation bodies began to take notice. In 1980 the Fauna Preservation Society symbolically changed its name to the Fauna and Flora Preservation Society, and in March 1984 the World Wildlife Fund and the International Union for the Conservation of Nature and Natural Resources launched an international programme for plant conservation. As part of this campaign, two books, both aimed primarily at the general market, have appeared almost simultaneously. *Green Inheritance* is published as the official book of the World Wildlife Fund's Plants Campaign and is written by Anthony Huxley, a well-known writer and lecturer on plants. *Our Green and Living World* has an appropriately international authorship of an African, two Europeans and an American.

The purpose of both books is to arouse concern over the quite staggering rate of destruction of much of the Earth's natural vegetation and to point to the consequences. Inevitably one draws comparisons between the two. As a plea for plants the case put by Anthony Huxley is the more compelling. The factual material is well-researched, and while there are lapses here and there when the subject becomes more physiological the text as a whole provides a fascinating and lucid account of mankind's relations with and dependence upon plants. Separate chapters deal with the role of plants as food, fuel, medicine and objects of beauty, as well as with the wider role of vegetation in atmospheric and soil processes. Accounts of the origins and spread of crop plants and the medicinal uses of plants are particularly good, the latter containing some quite astonishing information such as that on the uses or, more properly, abuses of the thornapple. Apart from Huxley's persuasive style, much of the success of *Green Inheritance* rests with its design. The combination of a continuous discursive text alongside short illustrated vignettes providing more detailed information works well, and the standard of graphics and art work is high.

Our Green and Living World covers much the same ground and overall, perhaps, is the more authoritative of the two. However, for the general reader it is likely that its message will be less compelling, the style sometimes being closer to that of an undergraduate text. Unlike *Green Inheritance* it includes eight chapters on different vegetation types from deserts to rain forests and from wetlands to oceans. It is also more comprehensive on the subjects of genetic conservation and under-exploited crops (the separate chapters on firewood and cellulose are particularly good). Like *Green Inheritance*, the production can only be described as lavish, some of the photographs being quite superb.

The overall lesson of the two books is clear, and in particular both focus attention on the devastation of the tropical rain forests. Five years ago the US National Academy of Sciences calculated that over 50 million acres were destroyed or seriously damaged each year and the UN's Food and Agricultural Organization estimated in 1981 that at present rates almost one-fifth of the world's remaining rain forest would have gone by the end of the century. Catherine Caufield's *In the Rain Forest* is a carefully researched collection of essays on various aspects of rain forest ecology, exploitation and destruction. Subjects range from the building of the town and dam of Tucurui in the Amazon basin to the discovery of quinine. Figures and statistics spill off the pages, and the value of the book is enhanced by good indexing, text notes and a comprehensive bibliography, but it is not — and does not pretend to be — a textbook on rain forest ecology. For anyone unfamiliar with the rain forest this is undoubtedly a good read and an intentionally perturbing one. □

Marian Dawkins

Strategies of Being Female: Animal Patterns, Human Choices.
By Evelyn Shaw and Joan Darling.
Harvester/Walker: 1985. Pp. 164. £12.95, $14.95.

IT WAS only in the last few pages of this book that I understood what the authors' purpose in writing it really was. Initially, I had thought it was going to be yet another polemic about the allegedly male-dominated sexist views of sociobiology in general and its treatment of sexual behaviour in particular. As I have never been able to understand this particular criticism of sociobiology (sociobiological emphasis on the evolutionary importance of female choice seeming, if anything, to overemphasize the role of females), I began the book by being somewhat out of sympathy with the authors. Some distinctly group selectionist phraseology — such as "reproducing in anticipation of the species' future" (p.32) and "the true biological reasons for having children [are] to assure the survival of the human species" (p.121) — only increased my antipathy.

But I was curious. How were the rampaging, promiscuous, initiative-taking females they cite from all corners of the animal kingdom going to be related to our own species, as promised in the introduction? Would promiscuous female fish or birds be used as a model for human beings? Would female hyenas, with their sham male genitalia, be held up as an example to us all?

Only in the last two chapters do Shaw and Darling argue that human females are in fact different from those of any other species. Females of other species may show a wide variety of sexual behaviour, but only human females can choose which particular one they will adopt for themselves. Looking after children is not, they argue, "biologically programmed in the genes of the female". "Words — not our hormones, and not some neurological Gestalt etched into our brains — teach us how to find a mate, who is appropriate as a mate and who isn't, when to have babies, how to give birth to them, and how to take care of them" (p.152). It is all the fault of culture, and the "myth of maternalism" in particular, that women are the ones most commonly adopting a child-caring role.

It is to attack this myth of maternalism — the claim that mothers are inherently better at caring for offspring than fathers — that turns out to be the book's main purpose. Men, it is argued, are just as good at looking after children as women are, if only they are given the chance. The trouble is they are so rarely given the chance. In a wide variety of cultures, women exclude men and refuse to allow them to be present at the birth of their own children. Shaw and

The most comprehensive one-volume work on astronomy ever published

Prepared by an international team of 44 astronomers, *The Cambridge Atlas of Astronomy* gives complete coverage of all aspects of astronomy. It features the latest results and breathtaking photographs from the Infrared Astronomical Satellite (IRAS), the X-Ray Detecting Satellite (Exosat) and the Solar Maximum Mission (SMM), as well as the finest new images from ground-based telescopes. Its 432 large-format pages contain over 700 photographs from the world's most prestigious observatories. This unique book includes sections on: The Sun; The Solar System; The Stars and the Galaxy; and the Extragalactic Domain.

★ Distinguished panel of consultant editors including Alex Boksenberg, Colin Ronan, James Pringle, Tony McDonnell and Nigel Henbest
★ Features on Space Telescope, the latest Canary Islands Telescopes and Halley's Comet
★ 1100 photographs and illustrations (680 in colour)
★ Extensive glossary and index
★ Large format – 368 x 268 mm
★ Foreword by Sir Bernard Lovell, General editors Jean Audouze and Guy Israel

PLANETARY SCIENCE

New Views on an Old Planet
Continental Drift and the History of Earth

TJEERD H. VAN ANDEL

In this book, Professor van Andel, a distinguished earth scientist, interweaves the major strands of change taking place on the earth – continental drift, climatic fluctuations and the progression of life – into a carefully constructed historical account of the evolution of the earth

0 521 30084 3 **£15.00 net/$19.95**

Recent Advances in Planetary Meteorology

GARRY E. HUNT

This landmark volume assembles seven invited and original papers by well-known workers in the field of planetary meteorology. An important feature of the book is the description of planetary atmospheres on a comparative basis

0 521 25886 3 **£20.00 net/$39.50**

Global Change

T. F. MALONE and **J. G. ROEDERER**

A multidisciplinary, integrated approach is necessary if we are to understand how our planet functions and thereby deal more effectively with environmental crisis This collection of papers, (the result of a symposium sponsored by ICSU in Sept 1984) will form the basis for such an approach

0 521 30670 1 **£35.00 net/$59.50**

Forthcoming (May)

BIOLOGY

Biotechnology of Malting and Brewing

JAMES S. HOUGH

This is a clear concise account of malting and brewing processes and the science on which they are based It is written in the context of modern developments and the problem of the bacteria that commonly contaminate beer is carefully examined

0 521 25672 0 **£20.00 net/$39.50**

Cambridge Studies in Biotechnology 1

Viruses and Cancer

Edited by **P. W. J. RIGBY** and **N. M. WILKIE**

The fourteen chapters consider the molecular biology and the biology and epidemiology of those viruses which appear to have a role in human cancer. Cellular oncogenes are also considered

0 521 26867 2 **£32.50 net/$64.50**

Society for General Microbiology Symposium 37

PHYSICS AND ASTROPHYSICS

Accretion Power in Astrophysics

J. FRANK, A. R. KING and **D. J. RAINE**

This advanced textbook gives an account of the accretion of matter by massive astronomical objects, setting out the physics of the accretion process in detail.

0 521 24530 3 **£30.00 net/$59.50**

Quantum Field Theory

L. H. RYDER

This advanced textbook describes the ideas and techniques of quantum field theory A brief survey of particle physics is followed by a study of the quantum theory of scalar and spinor fields, which then moves on to gauge fields

0 521 23764 5 **£40.00 net/$74.50**

NEW TECHNOLOGY in BIOTECHNOLOGY

DON'T MISS THIS OPPORTUNITY

to catch up with New Technology in Biotechnology

In the past five years, even the enthusiasts of the new biotechnology industry have often been surprised at the speed with which new opportunities have emerged.

THE OBJECTIVE of this *Nature* conference (the second to be held in Britain) is to provide a survey of the recent research that will influence the evolution of biotechnology in the next few years.

PARTICIPANTS in the conference will be provided in advance with a selection of reading matter intended to provide background to particular talks.

JOIN US

at NATURE'S fourth international conference, to be held at the Novotel London, June 25th-27th, 1985

CONFERENCE PROGRAMME

Day 1 Tuesday, June 25th

Morning **enzymes, immunogens**
Dr. D Thomas, Université de Technologie de Compiègne
Dr G. Winter, MRC Laboratory of Molecular Biology, Cambridge
Dr. A Klug, MRC Laboratory of Molecular Biology, Cambridge.

Afternoon **antibodies**
Dr J. Birch, Celltech Ltd , Slough
Dr M Neuberger, MRC Laboratory of Molecular Biology, Cambridge
ROUND TABLE DISCUSSION

Day 2 Wednesday, June 26th

Morning **biosensors**
Dr M Flanagan, University College, London
Professor I J Higgins/Dr A. Turner, Cranfield/ Leicester.

micro-organisms
Dr. S Emtage, Celltech Ltd , Slough

Afternoon **micro-organisms** continued
Professor D Hopwood, John Innes Institute, Norwich
Dr B Carter, Searle R&D, High Wycombe
ROUND TABLE DISCUSSION

Day 3 Thursday, June 27th

Morning **mammalian systems**
Professor P Tiollais, Institut Pasteur, Paris
Dr A Levinson, Genentech, San Francisco
Dr R L Brinster, University of Pennsylvania

Afternoon **plants**
Professor M Fowler, Wolfson Institute, Sheffield
Professor J Schell, Max Planck Institut, Koln
ROUND TABLE DISCUSSION or FINAL TALK

POSTER SESSIONS will be held each day and will be open to those registering for the conference Please send a title and a brief synopsis to Dr Peter Newmark, Deputy Editor, Nature, 4 Little Essex Street, London WC2R 3LF UK

SPACE IS LIMITED — REGISTER NOW!

TO REGISTER, return the form below with your cheque or authorised purchase order from your organisation TODAY!
Applications are accepted only on completion of a booking form We ask you to complete *one form per person*
We cannot guarantee to accept applications received after June 3rd, 1985

THE FEE is just £170 plus VAT for the duration of the conference or £74 plus VAT per day This includes entrance to all sessions, mid-morning coffee, afternoon tea and advance reading material Applications without payment will be acknowledged but will not be *confirmed* until payment is received In cases where a participant is being sponsored by an organisation, the organisation will be invoiced and once payment has reached us the participant will be sent confirmation of his or her place

ACCOMMODATION has been reserved in the NOVOTEL and elsewhere for conference participants A booking form will be sent to you as soon as we receive your registration

THE CONFERENCE DINNER will be held on Wednesday, June 26th This is always a popular event and SPACE IS LIMITED so make your reservation on the form below today The cost will be £18

NOTE: Cancellations received before May 27th, 1985 will be refunded less a processing charge No refunds can be made after this date

---

TO REGISTER FOR THE CONFERENCE, please return this form with your payment to **DEBORAH JONES,**
Conference Administrator,
Macmillan Conferences & Exhibitions,
4 Little Essex Street,
London WC2R 3LF, U K.

Darling argue that if only men could be present at the birth, they too would form strong bonds with their children and take on the care-taking role usually associated with mothers.

In support of this idea, they cite male wild-dogs, male marmosets and other species in which males take an active part in looking after the young. They also quote Rosenblatt's finding that male rats will

Kevin Carlson/Ardea.

Mother love — black-faced vervet monkey with infant.

begin to lick and retrieve young after they have been exposed to them for several days. The male's tendency to care for young is latent and revealed only if given the opportunity: "And just like a father rat, the human father is denied access to the environmental cues that would turn on his 'maternal' behaviour" (p.148).

There may or may not turn out to be something in all this. It is an interesting hypothesis, one which is certainly worth thinking about. What is disturbing to me is the way it is put over. Perhaps this is simply because the book is written in a popular style. Maybe words such as "babes" and "critters" have to be used to make sure readers do not feel overwhelmed by technical jargon; maybe a case has to be overstated in order to attract a public who would be bored by too much weighing up of evidence. But do we have to swing from male sexism to an equally unattractive female sexism? If we accept that women may wish and be able to fulfil a wider variety of roles than they often do, do we have to see society purely in terms of womens' choices and womens' destinies?

Shaw and Darling emphasize that "female" does not have to mean passive, meek or monogamous. But at the same time, perhaps unintentionally, they make female wishes and female roles dominant, without explaining why this kind of sexism is any more convincing — or any more acceptable — than the male kind. □

Ways to get back to the track

David Pimentel

State of the World 1985: A Worldwatch Institute Report on Progress Toward a Sustainable Society.
Project director Lester R. Brown.
W. W. Norton: 1985. Pp.301. Hbk $22.75, £18.95; pbk $9.50, £7.95.

IN PUBLISHING this detailed analysis of "the state of the world", the Worldwatch Institute has performed a valuable service for the public, government and industry. Examined in it are the interdependence of human population, global environment and world economy. Specifically, the authors assess the effect of population growth on deforestation, overgrazing, soil erosion, atmospheric pollution, and water and energy shortages. With this as a basis, they go on to consider the influence of natural resource degradation and resource shortages on the economy and standard of living of society.

Early in the book Brown and his colleagues tackle the question of whether climate change in some regions of the Earth may be population induced. They suggest that, indirectly, population growth may reduce rainfall because of overgrazing and other activities that remove or reduce vegetation cover. The increased exposure of bare soil increases the albedo: "Where this happens, as on the fringes of the Sahara, the affected areas reflect more heat into space". Canadian meteorologist, Kenneth Hare, who has investigated desertification in Africa, is quoted as concluding that "we seem to have arrived at a critical moment in the history of mankind's relation to climate. For the first time we may be on the threshold of man-induced climatic change". If indeed water shortages are population induced, then the decline can be reversed in some regions only by massive programmes in family planning, tree planting, soil and water conservation, and ecological–agricultural development on a huge scale.

The authors acknowledge the fact that major efforts to produce more food per hectare of land have slowed the growth of hunger, noting that agriculturalists have made use of biological diversity to breed new crop varieties that are more efficient in converting water and fertilizers into grain and other foods. At the same time, farmers have increased the amount of land cultivated and have greatly expanded the use of irrigation and fertilizers. Irrigation, for instance, has grown nearly three-fold since 1950 and fertilizer usage about nine-fold during much the same period. All these strategies have increased crop yields.

It remains to be seen, however, how far agricultural technology can go in producing more food from the world's limited arable land resources. We already know that there are certain physical and chemical constraints on the capacity of plants to capture and fix solar energy into biomass. Recognizing such limitations, the authors question whether biotechnology will make the major changes necessary to continue improving yields. A major concern to emerge here is the effect that the rapid loss of biological diversity will have on the success of biotechnology and genetic engineering, but in placing emphasis on this point the authors neglect to explain that *most* species in nature are vital to the normal functioning of the ecosystem. For example, agriculture cannot function successfully with only its crop and livestock species; many organisms, especially the small organisms (such as microbes and insects) are also essential. Thus on a hectare of good land with ample water, the small organisms outweigh human biomass by at least 200 times and carry out the vital tasks of degrading wastes and chemical pollutants, and of recycling other resources.

In a chapter on energy efficiency, William Chandler reports on the important role that fossil energy plays in producing food, purifying water, protecting us from numerous kinds of diseases and transporting resources from one region to another. Several sound arguments support the view that conservation of energy and improved energy efficiency are necessary for economic improvement in both developing and developed countries. But although fossil energy is essential to our present standard of living, almost everyone agrees that new sources of energy are needed, preferably renewable in form. However, the chapter entitled "Harnessing Renewable Energy" is rather disappointing. Several of the sources cited lack scientific credibility. For example, one paper quoted here reports that producing ethanol from corn grain provides a net energy return. This is not so; in fact, the net energy loss is about 30 per cent greater than the ethanol energy produced.

Also highlighted is the idea of shifting from the corn–soybean crop mix now typical in the mid-west of the United States to a corn–sugar-beet mix. This proposed plan, which is supposed to supply all food needs for livestock plus up to 700 million barrels of ethanol, has numerous technological and agricultural flaws and has been

Conservation in Britain

In association with the publisher Webb & Bower, and sponsored by Gulf Oil, the Conservation Foundation have published *The Conservation Review*, their third annual report for "everyone concerned with preserving our heritage and natural environment".

The *Review* is intended to increase public awareness of environmental issues and draw attention to the activities of various organizations, local, national and international. Among the contributors are David Bellamy, Patrick Jenkin, Tony Soper and Jean Medawar. Price is hbk £10.95, pbk £4.95.

discounted by most energy specialists. Further, nowhere do the authors acknowledge the environmental risks associated with certain renewable systems. For example, the widespread burning of crop residues and dung as a fuel is severely intensifying soil erosion and water run-off, and is robbing the soil of essential nutrients. Because soil erosion and water run-off are a major feature of the *Report*, it is especially unfortunate that biomass energy systems are not identified as major causes of these problems. There are also drawbacks to hydropower, but again no mention is made of them. Dams and reservoirs have to be constructed to run hydropower systems, and in the United States, for instance, about 13,000 hectares of productive agricultural land has to be flooded per 1×10^9 kWh/yr of electricity produced (sufficient electricity for a city of 100,000). This is not to imply that hydropower is not a valuable energy system in the United States and many regions of the world, but that environmental risks should be evaluated to determine if the benefits for a region outweigh the costs.

One of the most challenging aspects of the resource and environmental problems facing us today is their "gradual, insidious nature". For example, a single rain storm may erode 1 mm of soil weighing 15 tonnes from a hectare. That loss may be imperceptible, but it does not take many rain storms and many years to remove the 2.5 cm of topsoil that generally requires 200 to 700 years to replace. As Brown and Wolf point out, "few countries will succeed in attempts to boost domestic food at the rate demanded by population growth if soil-depleting agriculture continues".

The authors of the *Report* clearly explain that soil, water, energy and biological resources are being threatened not only by the rapidly growing population but also by poor management practices in agriculture and other industries. Further, many excellent plans are suggested for tackling the problems. But, as they caution, long-term solutions will require the efforts of individual intellects and of politicians to get society back to the track — the intellects to identify the direction for change, and political leadership to devise and carry out the appropriate policies for stabilizing populations and effectively managing environmental resources.

State of the World is a thorough and up-to-date examination of the influence of mankind on the Earth's various resources. Particularly helpful and timely are the solutions to the complex problems that are identified in the book. This is an exceptionally well-written report which scientists and industrial and political leaders would do well to read and to act upon. □

David Pimentel is Professor of Insect Ecology and Agricultural Science at the College of Agriculture and Life Sciences, Cornell University.

Biology as science

A.J. Cain

The Cambridge Encyclopedia of Life Sciences.
General editors Adrian Friday and David S. Ingram.
Cambridge University Press: 1985. Pp.432. £25, $45. To be published on 9 May.

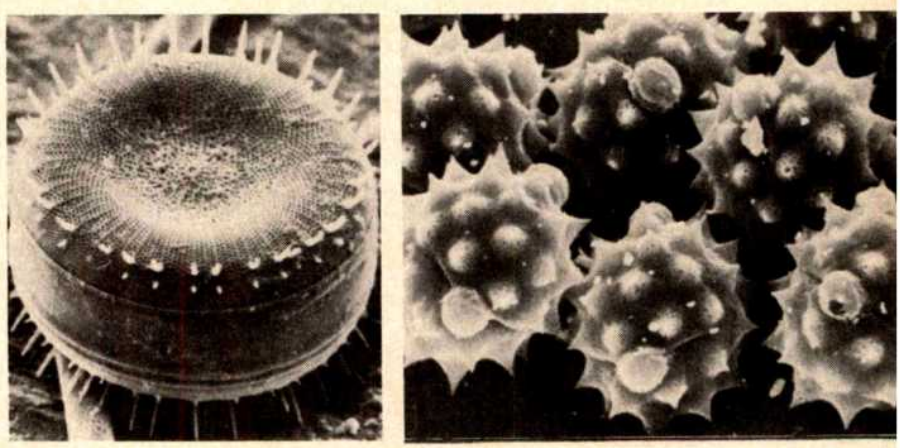
TO TRY to encompass within a volume of 432 pages a complete encyclopaedia of the life sciences strikes one as a most noble aim and a forlorn hope. The editors and contributors have succeeded in this book to a really remarkable degree.

The volume is divided into three parts: "Processes and Organisation" (the cell, the organism, genetics, behaviour and sociobiology, ecology); "Environments" (marine, coastal, terrestrial, freshwater and wetland, living organisms as environments); and "Evolution and the Fossil Record" (the evolutionary process, palaeontology, early events in evolution, origin and development of the land flora and fauna, recent history of the flora and fauna). A classification of living organisms, a species index (generic also) and a subject index complete the book.

The contents page refers under Part 2 to what appears to be an unnumbered chapter on biogeographical zones. The relevant pages in fact carry a set of maps only, and neither biogeography nor any names of biogeographical regions appear in the subject index. There are, however, excellent accounts of plate tectonics, numerous maps of the drifting continents, and much information on regional history and animal diversity in the section on the origin and development of the land flora and fauna, the best place to discuss the development of biogeographical diversity.

The book is written in a very readable style and has obviously been most carefully corrected in proof — one of the very few books I have seen in recent years that can be put into the hands of the young without a warning against bad spelling and grammar. It is a model of exposition, excellently illustrated. In the words of the editors:

The Cambridge Encyclopedia of Life Sciences is not a natural history cataloguing the living world, it does not attempt to argue a case for or against biological conservation, nor does it consider the yet greater ethical problems which arise from the genetic manipulation of cells. Instead, the *Encyclopedia* seeks to present biology as a science, and in addition constitutes a plea for considering all biological phenomena as indissolubly linked, a circumstance which underlies both the frustration and the fascination felt by all life scientists.



Inevitably, the necessary compression means that many topics can only be treated summarily, as a series of key concepts, their interrelations, and a brief mention of their empirical basis. In some ways this is a positive advantage, forcing the writers to get to the real bones of the subject. One could give a series of lectures on the single paragraph (p.296):

Some biologists have argued that if we can reconstruct the pattern of evolution, the *phylogeny*, this will provide insight into the ways in which evolutionary change occurs. The opposite point of view is that knowledge of the processes of evolutionary change is essential before it is possible to find out the pattern of relationships between organisms.

Yes, indeed!

Equally inevitably, specialists will be dissatisfied because so much can only be mentioned. It would take a team of reviewers as large as the team of authors and editors (31, 22 of them in Cambridge) to deal with the chapters fully. In my own speciality, I notice only the total absence of ring species and allopolyploid plants from the section entitled "Mechanisms of Speciation", in which too much space is given to the latest fads in speciation theory. As against that, what a pleasure it is to see a proper discussion of parasites in the section on living organisms as environments. Surely there are more species of parasitic than of free-living organisms, yet this major aspect of evolution and the ecosystems of the world is usually mentioned merely in passing except in highly specialized texts. □

A.J. Cain is Derby Professor of Zoology at the University of Liverpool.

A matter of taste

Nicholas Kurti

On Food and Cooking: The Science and Lore of the Kitchen.
By Harold McGee.
Charles Scribner's Sons: 1984. Pp.684. $29.95.

How refreshing it is to be treated to an inspiring blend of botany, zoology, physiology, anatomy, biochemistry, and, of course, gastronomy. In his introduction to what is almost a scientific, literary and historical encyclopaedia of food and its enjoyment, Dr McGee admits to the importance of experience, intuition and a discriminating palate in preparing food, but he also asserts that "a general understanding of what is going on in the pan ... can compensate for a lack of familiarity with particular ingredients and techniques". The book is studded with examples of the beneficial intrusion of science into the kitchen, often expressed in vivid terms, such as the remark that "roast and meringue are different outcomes of the same process [but] the knowledge of protein coagulation need not diminish the pleasure in consuming a well-made roast or a meringue". McGee also reminds us that "while we may be up on Black Holes and the Big Bang and the Primordial Soup we can't explain how flour thickens soup".

Mary Evans

Nearly four-fifths of the book is devoted to accounts of the foodstuffs that go into our diet, grouped according to their origin rather than their chemistry. Scientific explanations are interspersed with historical remarks and tips on how to avoid or rectify cooking disasters and there is no lack of debunking (or justifying, as the case may be) of culinary and dietary fads. For example the much-vaunted blessings of fibre and bran are discussed critically but with tolerance. The author recognizes the nutritional value of whole-grain bread, but also quotes the rickets epidemic in Dublin during the Second World War when rationing of dairy products led to a low calcium intake, the assimilation of which was inhibited by the high bran content of the diet.

In discussing the progress of meat from the slaughterhouse to the table, McGee emphasizes the need to keep the animal free of stress before slaughter; muscular tension depletes the glycogen supply, less lactic acid accumulates in the muscle after slaughter and the result is inferior "dark-cutting" meat. The use of tenderizers based on naturally occurring proteolytic enzymes is also described but, surprisingly, the use of the hypodermic syringe to obtain even distribution of the tenderizer is not mentioned. And although it is true that these enzymes work faster at higher temperatures, I have found that fresh pineapple juice will tenderize pork chops at room temperature in 2-4 hours.

There is too an excellent explanation of the conflicting demands on the *rôtisseur* trying to achieve the conversion of the collagen in connective tissues into gelatin (a slow process) without drying out and toughening the muscle fibres. There is, however, nothing about the low-temperature (less than 75°C) roasting technique pioneered by Sir Benjamin Thompson, Count Rumford (1753-1814), the Anglo-American soldier, statesman and natural philosopher who was also a culinary innovator. This method works well: I proved its excellence to my own satisfaction — and, apparently, to the satisfaction of those who ate the joint — by roasting a 4lb leg of lamb for 8 hours in a slow oven.

McGee gives a full account of the arguments about the use of copper bowls when making meringues, culminating in a re-run of the beautiful piece of work undertaken at Stanford University by McGee and his colleagues (*Nature* **308**, 667; 1984) which showed conclusively that traces of copper ions do indeed make egg-white foam more durable through the formation of a copper-protein complex. It is a pity that neither this book nor the original article indicates the minimum amount of copper needed per egg. It is bound to be very small and phials of "meringue-improvers" could be sold at a price many thousand times the value of their contents. (I found it odd, incidentally, that albumen coagulation (which occurs at around 60°C) is regarded as an essential feature of meringues; it is well known that meringues can be made at considerably lower temperatures, even at 20°C, especially if reduced pressure is used.) There are many other useful tips for the amateur confectioner; here at last, for instance, we have a clear explanation of how peppermint cream gets into the thin crisp chocolate of after-dinner mints.

It is in the chapter on sauces that the enthusiasm of the gastronome, the artistic skill of the cook and the critical approach of the scientist shine most brightly. This is a veritable *saucier*'s vade-mecum. All the traditional tricks are explained, new techniques are suggested and there is also, among other good things, a full account of the saga of the Resurrection of a Curdled Sauce Béarnaise which began in 1977 with an article in *Nature* (**270**, 572) by C.M. Perram, C. Nicolau and J.W. Perram.

More prosaically, in writing about food additives McGee reminds those with a taste for nostalgia of "bread mixed up with chalk, alum and bone ashes", of "greens boiled with brass half-pence" and "butter manufactured with candlegrease and kitchen stuff", practices which were prevalent in mid and late eighteenth century England. Smollet bemoaned the fact that "these enormities might be remedied, but the wise patriots of London have taken into their heads that all regulation is inconsistent with liberty". We are better off now, inasmuch as food adulteration on the scale of the past can no longer be perpetrated with impunity, and the author illustrates, with the help of the cases of saccharin and sodium nitrite, the difficulties in arriving, on the basis of often incomplete scientific evidence, at solutions which satisfy public demand and reduce the risk to public health. Similar good sense characterizes the two brief sections "Food and the Body" and "The Principles of Cooking", though I was surprised that nowhere in the book are calories mentioned. I should liked to have seen at least a modest table giving the values of the principal foods. This omission may have been deliberate, however, the author wanting to emphasize in this way a view, latent throughout the text and expressed felicitously at the end of the chapter on nutrition, that "Nutrition by the numbers is no guarantee of the good life and probably precludes it by overriding the calls of appetite and pleasure".

Dr McGee's book brings to mind a remark of Count Rumford:

> The advantage that would result from an application of the late brilliant discoveries in philosophical chemistry, and other branches of natural philosophy of mechanics, to the improvement of the art of cookery, are so evident and so very important that I cannot help flattering myself that we shall soon see some enlightened and liberal-minded person of the profession take up the matter in earnest, and give it a thoroughly *scientific* investigation.
>
> In what art or science could improvements be made that would more powerfully contribute to increase the comforts and enjoyments of mankind.

Two centuries later, with the publication of *On Food and Cooking*, gastronomes and scientists alike can rejoice that Rumford's hopes are on their way to fulfilment. □

Ciba Foundation Symposia

The value of preventive medicine

Ciba Foundation Symposium 110
Chairman: A G Shaper, Royal Free Hospital, School of Medicine, London

An essential book for all those involved in medical research, therapeutic medicine, preventive medicine and health economics.

1985/0 272 79784 7/264 pp

Enzymes in organic synthesis

Ciba Foundation Symposium 111
Chairman: A R Battersby, University Chemical Laboratory, Cambridge, UK

Practical, theoretical and economic aspects of enzymic methods are considered and applications of mammalian and microbial enzymes are described, with details of the synthesis of many types of compounds.

1985/0 272 79785 5/256 pp

Microbial toxins and diarrhoeal disease

Ciba Foundation Symposium 112
Chairman: R L Guerrant, University of Virginia, USA

This book provides fresh insights into the molecular and cellular mechanisms of toxin action which are leading to new approaches to the treatment and prevention of these devastating diseases.

1985/0 272 79786 3/296 pp

Retinoids, differentiation and disease

Ciba Foundation Symposium 113
Chairman: M B Sporn, National Cancer Institute, Bethesda, USA

This work provides a basis for the use of retinoids in the treatment of certain skin disorders and for their potential use in the treatment or prevention of diseases such as bladder and breast cancer, rheumatoid arthritis and leukaemia.

1985/0 272 79813 4/296 pp

All volumes are hardback, illustrated and measure 229 × 152mm. The price is **£27.95** net (UK), **$35** (USA) per volume.

For further details contact **Pitman Publishing Ltd, 128 Long Acre, London WC2E 9AN.**

Ciba Foundation Symposia are available in North America from the **Medical Education Division, Ciba Pharmaceutical Co, P.O. Box 18060, Newark, NJ 07101, USA.**

Historical Monitoring

The baseline for pollution problems today

This is the first major text to examine the use of biotic and abiotic materials as indicators of past environmental contamination.

The materials discussed include ice, sediment cores, peat, tree rings and preserved botanical and zoological materials as well as human remains.

The available literature is critically reviewed and the usefulness of each material as a monitor is evaluated.

362 pp, 87 figures, 30 tables, 658 references.

New from

BIOPRESS LIMITED

PROGRESS IN PHYCOLOGICAL RESEARCH — VOLUME 3

An exciting new series of in-depth essays of wide interest to biologists

CONTENTS

Evolution of the Phaeophyta with Particular Reference to the Fucales . . . Margaret N. Clayton

Diatom Locomotion . . . Lesley A. Edgar & Jeremy Pickett-Heaps

The Biology of Freshwater Red Algae . . . Robert A. Sheath

Photoperiodism and Phycology . . . Matthew Dring

The Eyespot Apparatus of Flagellated Green Algae: A Critical Review . . . Michael Melkonian and Horst Robenek

The Ecology of Estuarine Sediment-Inhabiting Diatoms . . . Wim Admiral

Biogenesis of Tropical Reefs: The Contribution of Algae . . . Mark M. Littler and Diane S. Littler.

There are 387 pages with 285 figures including many electron micrographs. Hardback cover. ISSN 01678574. Price is £39.50 (US$59.50).

Please order direct from Biopress Limited, "The Orchard", Clanage Road, Bristol BS3 2JX, England for immediate delivery.

ANNOUNCING THE PROGRAM FOR

FASEB SUMMER RESEARCH CONFERENCES FOR 1985

The Federation of American Societies for Experimental Biology will again present a series of Summer Research Conferences designed to meet the demand of experimental biologists for *intimate and detailed analysis* of current research in areas of intense scientific interest. The conferences, held weekly at the Vermont Academy in Saxtons River, Vermont, will be limited to an attendance of 150 persons and will be by invitation upon application. A conference fee of $260 per person covers one week's room, board and registration. For additional information, a complete program and application form, see the February issue of FEDERATION PROCEEDINGS, Volume 44, Number 2, or contact Robert W. Krauss, 9650 Rockville Pike, Bethesda, MD 20814 (301) 530-7093.

NEUROTRANSMITTERS (June 9 - 14)
Chairman: Bruce Howard, UCLA Medical School
Vice-chairman: William O. McClure, University of Southern California
Regulation of Neurotransmitter Metabolism I&II. A. Tank, N. Weiner, T. Joh, E. Lewis, E. Diliberto, R. Zigmond, B. Collier, D. Jendon; **Neuropeptides.** R. Axel, J. Roberts, G. Sutcliff, R. Scheller, J. Douglas, L. Eiden, R. Evans; **Synaptic Vesicle Structure.** D. Aunis, C. Creutz, V. Whittaker, D. Njus; **Transport and Storage.** S. Parsons, S. Schuldiner, P. Dannies, B. Kanner, G. Rudnick; **Neurotransmitter Release and Membrane Retrieval I&II.** R. Siraganian, P. Greengard, B. Howard, R. Holz, T. Reese, J. Meldolesi, H. Winkler, C. Unsworth, R. Miller; **Modulation of Release.** D. Michaelson, M. Dubocovich, J. Brown, J. Cooper, M. Livingstone; **Neurotoxins.** W. McClure, J. Dolly, E. Yavin, D. Yoshikami.

MICRONUTRIENTS: TRACE METALS (June 16 - 21)
Chairman: Edward Harris, Texas A & M University
Vice-chairman: Robert Cousins, University of Florida
Iron Absorption, Metabolism and Utilization. P. Saltman, H. Munro, E. Morgan, G. Bates; **Metabolism and Function of Copper.** J. Prohaska, M. Linder, R. Rucker, M. Ettinger; **Biological Functions of Selenium.** J. Rotruck, R. Burk, H. Cohen; **Workshop: Methods of Nutritional Assessment.** C. Veillon, D. Gordon, W. Mertz, O. Levander; **Zinc Homeostasis and Function.** R. Cousins, B. O'Dell, M. Hambidge, I. Bremner; **Workshop: Approaches to the Study of Metabolism of Trace Metals.** F. Nielson, E. Morgan, A. Prasad, J. Spears; **Trace Metals in Reproduction, Growth and Development.** J. Apgar, P. Gullino, L. Hurley, K. Falchuk; **Abnormalities in Trace Metal Metabolism.** I. Sternlieb, D. Danks, M. Failla; **Role of Trace Metals in Disease Resistance and Therapy.** J. Sorenson, G. Brewer, G. Fernandes, D. McMurray.

SMOOTH MUSCLE (June 23 - 28)
Chairman: Julius Allen, Baylor College of Medicine
Vice-chairman: R. Kent Hermsmeyer, University of Iowa
Contractile Proteins. D. Hartshorne, R. Murphy, J. Stull, P. DeLanarolle, K. Campbell; **Excitation-Contraction Coupling.** D. Harder, G. Haeusler, C. Van Breeman, R. Paul, T. Godfraind; **Mechanics.** B. Johansson, F. Fay, R. Meiss, P. Dobrin, M. Mulvaney; **Calcium Localization.** V. Kreye, L. McGuffee, K. Morgan, M. Sturek, R. Phair; **Ion Pumps.** A. Brading, A. Jones, G. Siegel, S. Navran, N. Speralakis; **Membrane Receptor Excitation Mechanisms.** C. Cohen, P. Abel, J. Singer, T. Bolton, H. Kuriyama; **Development, Hypertrophy and Protein Production.** R. Bevan, G. Owens, G. Gabella, R. Bagby, C. Seidel; **Hypertension.** H. Overbeck, M. Pamnani, W. Stekiel, S. Gray, W. Halpern.

LYMPHOCYTE & ANTIBODIES (June 30 - July 5)
Chairman: Henry Wortis, Tufts University School of Medicine
Vice-chairman: Cox Terhorst, Harvard Medical School
Strategies for Inserting Genes. R. Flavell; **Rearrangement and Expression of the Immunoglobin Repetoire.** F. Alt; **Antigen Presenting Cell Phenotypes.** M. Dorf; **B-Cell Activation.** D. Parker, A. DeFranco, C. Cowing, A. Abbas, R. Chesnut, B. Malynn; **Molecules Involved in T-Cell Activation.** C. Terhorst, T. Mak, W. Greene, L. Cantley; **The Function of Ly1 B-Cells.** C. Sidman, D. Sherr, L. Herzenberg, E. Vitetta; **Cytotoxic T-Cell Effector Functions.** P. Henkart, E. Podack, A. Greenberg; **Epstein Barr Virus & B-Cell Transformation.** D. Thorley-Lawson, E. Kieff, J. Sullivan, G. Lenoir; **HLA Gene Structure & Disease.** B. Dupont.

SOMATIC CELL GENETICS (July 7 - 12)
Chairman: Thomas Caskey, Baylor College of Medicine
Vice-chairman: Phillip Coffino, University of California/San Francisco
Oncogenes. I. Verma, I. Sigal, C. Sherr, T. Kataoka; **Somatic Cell Selection Workshop.** P. Coffino; **Cellular Receptors.** A. Ullrich; **Tissue Specific Gene Regulation.** W. Schaffner, T. Maniatis, D. Baltimore, P. Chambon; **Gene Walking Workshop.** H. Lehrach; **Transgenic Mice.** F. Constantini, R. Kraumlauf, R. Jaenisch, M. Evans; **Recombination.** R. Rothstein, F. Alt, M. Capecchi, M. Liskay; **Transgenic Workshop.** F. Constantini; **Gene Transfer.** T. Caskey, D. Miller, R. Mulligan, R. Kellems; **Cellular Immunity.** S. Tonegawa, T. Mak, W. Green, D. Raulet; **Vector Development and Usage Workshop.** D. Miller; **Gene Mapping.** J. Gusella, D. Drayna, D. Housmann, H. Lehrach, F. Collins; **Plant Somatic Cell Genetics.** L. Bogorad, R. Chaleff, R. Fraley

DEVELOPMENTAL NEUROBIOLOGY (July 14 - 19)
Chairman: Nicholas Spitzer, University of California/San Diego
Vice-chairman: Lynn Landmesser, University of Connecticut
Lineage Relationships in Vertebrates and Invertebrates. N. Spitzer, D. Weisblat, K. Herrup; **Lineage Probed with Molecular Markers.** L. Landmesser; **Neurite Outgrowth – Cellular Mechanics.** N. Spitzer, P. Letoumean, K. Pfenninger, C. Lance-Jones; **– Pathfinding.** L. Landmesser, C. Goodman, J. Palka, U. Rutishauser; **Development of Voltage-Dependent Ion Channels.** N. Spitzer, C. Bader, G. Strichartz, S. Siegelbaum; **Development of Neurotransmitter-Activated Channels.** L. Landmesser, E. Cooper, N. Nathanson; **Biochemical Correlates of Development – Neurotransmitter Synthesis.** N. Spitzer, S. Landis, I. Black, J. Barker; **– Hormonal Triggers and the Roles of Surface Molecules.** L. Landmesser, P. Patterson, J. Sanes; **Specificity of Neuronal Connections.** N. Spitzer, W. Thompson, D. Purves, S. Easter, E. Frank.

GASTROINTESTINAL DIFFERENTIATION (July 21 - 26)
Chairman: Lenard M. Lichtenberger, University of Texas Medical School/Houston
Vice-chairman: Susan J. Henning, University of Houston
General Discussants: F. Moog, E. Lebenthal, D. Alpers, R. Lester, P. Sunshine; **Molecular and Cellular Mechanisms of GI Ontogeny.** K. Haffen, G. Teitelman, J. Gordon, P. Colony; **Ontogeny of GI Endocrine Cells.** A. Pearse, L. Lichtenberger, A. Andrews, J. Polak; **Innervation and Motility of the Developing Gut.** M. Gershon, Y. Ruckebusch, F. Morriss; **Development of Immune and Barrier Properties of the GI System.** J. Trier, M. Neutra, R. Rodewald, W. Walker; **Development of the Salivary and Pancreatic Secretion.** R. Redman, W. Ball, L. Cutler, J. Morisett, J. Jamieson; **Development of the Gastric Secretion.** L. Johnson, J. Forte, E. Dial; **Development of Intestinal Digestion.** S. Henning, K.Y. Yeh, D. Menard, G. Gall; **Development of Intestinal Absorption.** O. Koldovsky, S. Toverund; **GI Differentiation in the Adult.** N. Kretchmer, R. Grand, A. Zweibaum, J. Madara.

MECHANISMS OF CARCINOGENESIS (July 28 - August 2)
Chairman: Charles Sherr, St. Jude Children's Research Hospital
Vice-chairman: Ellen Vitetta, University of Texas Southwestern Medical School
Oncogenes and Transforming Genes I. H. Hanafusa, J. Brugge, I. Verma, C. Sherr, T. Deuel; **Receptors and Hormones I.** M. Brown, T. Hunter, G. Carpenter, I. Pastan, A. Ullrich; **Hematopoietic Transformation.** C. Berard, T. Grat, A. Bernstein, O. Witte, D. Boettiger; **New Therapeutic Modalities.** A. Nienhuis, P. Martin, E. Vitetta, P. Thorpe; **Promotion, Chemicals, Radiation and Drug Resistance.** W. Haseltine, V. Ling, N. Colburn; **Host Response to Tumors.** M. Greene, R. Lynch, G. Nicolson, J. Forman; **Receptors and Hormones II.** C. Weissmann, K. Smith, T. Waldmann, G. Todaro, B. Ozanne; **Oncogenes and Transforming Genes II.** P. Leder, R. Eisenman, D. Lowy, G. Cooper, P. Neiman; **Insertional Mutagenesis and Enhancer Elements.** R. Jaenisch, G. Peters, G. Vande Woude, G. Khoury.

PROTEIN KINASES (August 4 - 9)
Chairman: James Niedel, Duke University Medical Center
Vice-chairman: Jyh-Fa Kuo, Emory University School of Medicine
Opening Address: P. Greengard. **Evening Address:** I. Pastan. **Protein Kinase C.** J. Kuo, R. Bell, P. Blumberg, W. Anderson; **Calmodulin Protein Kinase.** R. Adelstein, A. Means, R. Tsien; **Phosphatases.** C. Klee, E. Fischer, D. Brautigan; **Substrates.** P. Blackshear, L. Williams, J. Garrison, J. Cooper; **Receptor Phosphorylation.** R. Lefkowitz, R. Klausner, P. Liebman; **Signal Generation.** E. Lapetina, J. Williamson, L. Cantley, M. Smigel; **Gene Regulation.** D. Granner, R. Maurer, M. Rosenfeld, M. Greenberg; **Receptor Kinases.** S. Aaronson, W. Pledger, R. Davis.

BIOLOGY & CHEMISTRY OF VISION (August 11 - 16)
Chairman: Paul A. Hargrave, University of Florida Health Center
Vice-chairman: Meredithe Applebury, Purdue University
Rhodopsin Structure, Function and Topography. P. Hargrave, J. Findlay, R. Liu; **Visual Pigment Gene Structure.** M. Applebury, H. Khorana, J. Nathans; **Applications of Molecular Biology to the Study of Vision.** D. Bridges, J. Hurley, J. Piatigorsky; **Biochemistry of Visual Transduction.** P. Liebman, H. Kuehn, N. Goldberg, B. Fung; **Models for Visual Transduction.** E. Bownds, J. Brown, J. Korenbrot, R. Cote, J. Lisman; **Retinoid Metabolism and Transport.** J. Saari, D. Bridges, D. Bok, G. Chader, R. Rando; **Developmental Biology of the Retina.** D. Papermaster, C. Barnstable, I. Nir, S. Zipursky, J. Besharse; **Visual System Membranes: Components and Properties.** R. Cone, R. Molday, P. Witt, N. Colley; **Ionic Basis of Photoreceptor Transduction.** D. Baylor, K-W. Yau.

FASEB

Dynamic solidification of a binary melt

Herbert E. Huppert* & M. Grae Worster†

* Department of Applied Mathematics and Theoretical Physics, University of Cambridge, Silver Street, Cambridge CB3 9EW, UK
† Department of Mathematics, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139, USA

The fundamental physics and fluid dynamics of a solidifying two-component system cooled from below is analysed quantitatively. Theoretical results for the rate of growth of the solid are in good agreement with experimental measurements on crystallizing aqueous solutions. The results are applicable to the solidification of a wide variety of binary alloys.

THE cooling and resultant solidification of a melt is important in many different fields, including crystal growth[1,2], electrical engineering[3,4], geology[5,6], geophysics[7,8], metallurgy[9,10] and oceanography[11,12]. The investigation of the fluid dynamic processes which often dominate solidification has been advanced by the suggestion[13-15] that the mechanisms may be elucidated by laboratory experiments on the freezing of aqueous solutions. In some cases[14,15] the studies were aided greatly by the concurrent analysis of a predictive mathematical model. Here, we use this powerful approach and describe some simple experimental and associated theoretical models for the cooling and crystallizing at a horizontal boundary of an initially homogenous fluid. The aim is to highlight the fundamental phenomena and to minimize consideration of inessential details by studying a simple and straightforward situation. We use aqueous solutions because they are easy to handle in the laboratory, but the concepts developed are applicable directly to the solidification of a wide variety of binary alloys.

First, we discuss briefly the phase diagram of the solid/melt mixture and then concentrate on effects associated with cooling and solidifying a melt from below. We determine theoretically the rate of solidification if the solid/melt interface is perfectly flat and horizontal, and also evaluate the criterion for which the interface becomes unstable. In a series of laboratory experiments, we have grown ice with unstable interfaces from different aqueous solutions and we have developed a simple theoretical model whose predictions are in good agreement with the observations. Our main quantitative conclusions are theoretical and experimental relationships for the rate of growth of the crystal block, the total volume of solid produced and an expression for the volume fraction of the solid product.

Phase diagram

The chemical composition of the phase obtained by the solidification of a melt with two chemical components is determined at thermodynamic equilibrium by the phase diagram (Fig. 1). This diagram represents the chemical compositions of melt and solid in equilibrium with each other by the liquidus and solidus respectively. At a temperature and composition represented by a point above the liquidus, the system is liquid. Between the liquidus and the eutectic line, the solidus defines the composition of the material solidifying from the melt, and in general specifies solid phases whose composition differs from both the melt and the pure components of the system[6,9]. For most aqueous solutions and many binary alloys, however, the phase diagram has the special form illustrated in Fig. 1*a*, where solidification from a melt (solution) with sub-eutectic composition yields a solid phase consisting of a pure component (ice). It is usually the case that density in the melt is a much stronger function of composition than of temperature (see Fig. 1), which plays an important role in the fluid dynamics of solidification.

The solidification of a melt of eutectic composition, yielding solid of the same bulk composition, is equivalent to the solidification of a pure material. Otherwise, study of the process of solidification requires that melts with compositions greater and less than that of the eutectic must be dealt with separately, while the direction of cooling (from above or below) also requires distinctive treatment. Table 1 shows the 3×2 matrix by which the problems of solidification may be classified. What follows concentrates mainly on cooling from below of a melt whose composition is below the eutectic value.

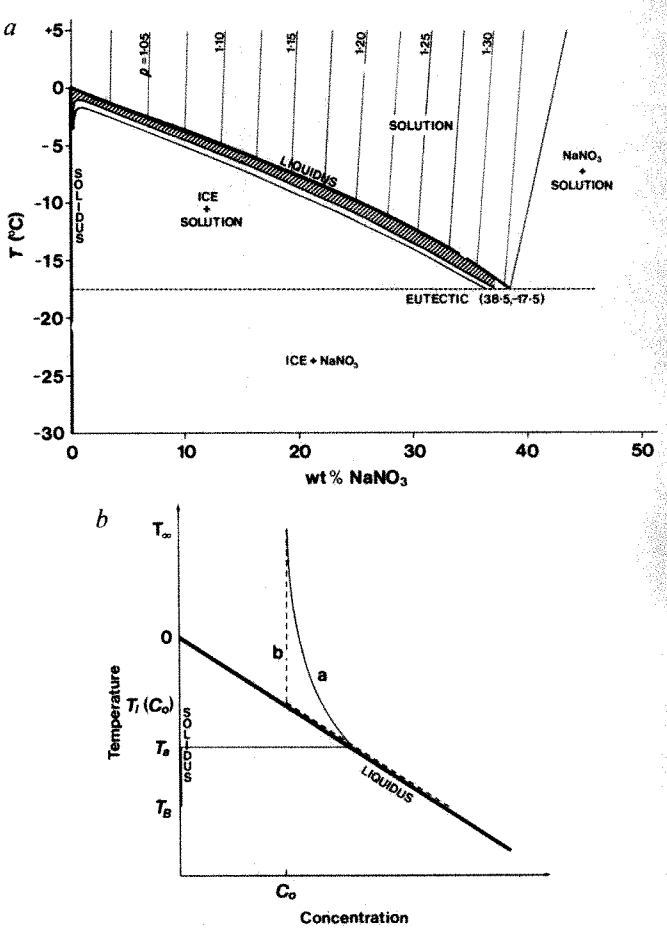

Fig. 1 *a*, Phase diagram for an aqueous solution of $NaNO_3$ (refs 20, 24) with axes of temperature and concentration. The same diagram acts as a schematic for a general binary alloy with components A and B. The figure also presents the lines of constant density with the density values attached. Hatched region, morphologically stable region for $T_\infty = 15$ °C. The curve just beneath the hatched region indicates the curve of marginal stability for $T_\infty = 30$ °C. In determining the curves the following values of the constant physical parameters have been used: $C_{p_m} = 1.0$ cal g^{-1} °C^{-1}, $C_{p_s} = 0.48$ cal g^{-1} °C^{-1}, $D = 10^{-5}$ cm^2 s^{-1}, $L = 80$ cal g^{-1}, $\kappa_m = 0.0013$ cm^2 s^{-1}, $\kappa_s = 0.012$ cm^2 s^{-1}, $\rho_s = 0.916$ g cm^{-3}. Further, the values of Γ and ρ_m were obtained as a function of C_0 from ref. 20. *b*, Phase diagram used here, with temperature and concentration axes chosen so that a solid of zero concentration forms at zero temperature. Heavy solid line, straight-line approximation to the liquidius. Thin curve a, temperature against concentration profile in the morphologically stable regime. Dashed curve b, approximate profile used in our model of the morphologically unstable regime.

Table 1 The six different cases that arise when an initially homogeneous solution is cooled at a horizontal boundary

	Cool from Above	Cool from Below	
$C > C_E$	13	25	Light fluid released
$C = C_E$	13	14	Uniform composition throughout
$C < C_E$	22	here	Heavy fluid released
	Thermally unstable	Thermally stable	

Numbers refer to the reference in which each case is discussed. See text for explanation of symbols.

Eutectic growth

The solidification of a melt of eutectic composition involves only variations in temperature, because the composition in the melt and solid is constrained to remain at the eutectic value. This situation is equivalent to one described by Carslaw and Jaeger[16], who present the analytical solution for a column of melt of infinite height whose initial temperature is T_∞ and which is cooled at a lower boundary whose temperature is T_B. We conducted two experiments using eutectic compositions of aqueous Na_2CO_3 (eutectic composition $C_E = 5.7$ wt%, eutectic temperature $T_E = -2.1$ °C) in an insulated Perspex tank 20 cm × 20 cm × 45 cm high. Our observations of the height of the compact eutectic solid as a function of time in one of our experiments are plotted in Fig. 2. They are in good agreement with the analytical solution, which attests to the reliability of our experimental methods.

Sub-eutectic growth

We have extended the study of the solidification of a eutectic melt to the case where the composition is not that of the eutectic but in which the initial uniform concentration of solute C_0 is less than C_E. Solid of composition $C = 0$ grows on the cooled boundary and, to begin with, we assume that the solid/melt interface remains flat and parallel to the boundary. The fluid released by the crystallization is relatively heavy and thus remains just above the interface, so that the concentration gradient which develops is stable. Thus, no physical motion takes place and the transport of heat and solute is by molecular diffusion alone. The governing equations are then those for heat transport (in one dimension, taken as z measured upwards from the cooled boundary) above and below the interface and for solute diffusion in the melt. The equations for the temperature $T(z, t)$ and the composition $C(z, t)$ are

$$\rho_s C_{p_s} \frac{\partial T}{\partial t} = k_s \frac{\partial^2 T}{\partial z^2} \quad \text{(for } z < h(t), \text{ the position of the moving boundary)} \tag{1}$$

$$\left.\begin{aligned} \rho_m C_{p_m} \frac{\partial T}{\partial t} &= k_m \frac{\partial^2 T}{\partial z^2} \\ \frac{\partial C}{\partial t} &= DL \frac{\partial^2 C}{\partial z^2} \end{aligned}\right\} (z > h(t); \text{ that is, for } z \text{ in the melt}) \tag{2, 3}$$

$$T = T_B \qquad (z = 0) \tag{4}$$

$$T \to T_\infty, \quad C \to C_0 \qquad (z \to \infty \text{ or } t \to 0) \tag{5}$$

The physical parameters are the solute diffusivity D, the thermal conductivity k, the density ρ and the specific heat C_p, all of which are considered to be constant. Subscripts s and m refer to properties of the solid and the melt, respectively. The difference in heat flux across the interface $z = h(t)$ results from the latent heat released on solidification. This can be expressed by

$$\rho_s L\dot{h} = -k_m \frac{\partial T}{\partial z}(h+, t) + k_s \frac{\partial T}{\partial z}(h-, t) \tag{6}$$

where a dot denotes a time derivative and L is the latent heat of fusion. Conservation of solute requires

$$C(h+, t)\dot{h} = -D \frac{\partial C}{\partial z}(h+, t) \tag{7}$$

Further, with the assumption that the solidification kinetics can be described by equilibrium thermodynamics, we require that the temperature and composition at the interface lie on the liquidus, which we approximate by the linear relationship

$$T = T_L(C) = -\Gamma C \tag{8}$$

This tacitly assumes, merely for convenience, that the liquidus temperature is 0 at zero composition, as it is for all aqueous solutions.

The system of equations and boundary conditions represented by equations (1)–(8) admits a similarity solution, with variable

$$\eta = \tfrac{1}{2}(Dt)^{-1/2} z \tag{9}$$

in which the interface has position

$$h = 2\lambda(Dt)^{1/2} \equiv \gamma_C^{t^{1/2}} \tag{10, 10'}$$

This similarity form of solution can be shown to be the only solution of the equations. The temperature and concentration fields, determined from equations (1)–(5), can then be expressed in terms of error functions[17] as

$$T(z, t) = T_B + (T_a - T_B)\,\mathrm{erf}\,(\varepsilon_S \eta)/\mathrm{erf}\,(\varepsilon_s \lambda) \qquad (z < h) \tag{11}$$

$$\left.\begin{aligned} T(z, t) &= T_\infty + (T_a - T_\infty)\frac{\mathrm{erfc}\,(\varepsilon_m \eta)}{\mathrm{erfc}\,(\varepsilon_m \lambda)} \\ C(z, t) &= C_0 + (C_a - C_0)\frac{\mathrm{erfc}\,\eta}{\mathrm{erfc}\,\lambda} \end{aligned}\right\} (z > h) \tag{12, 13}$$

where T_a and C_a are the temperature and concentration of the melt at the interface. There are two parameters $\varepsilon_{s,m} = (D/\kappa_{s,m})^{1/2}$, where $\kappa = k/\rho C_p$ is the thermal diffusivity. The interface conditions in equations (6)–(8) are now used to determine the eigenvalue λ from

$$\Gamma C_0 \left[\frac{F(\lambda)}{1 - F(\lambda)}\right]\left[\frac{\rho_m C_{p_m}}{F(\varepsilon_m \lambda)} + \frac{\rho_s C_{p_s}}{G(\varepsilon_s \lambda)}\right] = \frac{\rho_s C_{p_s} T_1}{G(\varepsilon_s \lambda)} - \frac{\rho_m C_{p_m} T_0}{F(\varepsilon_m \lambda)} - \rho_s L \tag{14}$$

where

$$F(x) = \pi^{1/2} x e^{x^2}\,\mathrm{erfc}\,x, \qquad G(x) = \pi^{1/2} x e^{x^2}\,\mathrm{erf}\,x$$

$$T_1 = T_L(C_0) - T_B, \qquad T_0 = T_\infty - T_L(C_0)$$

The solute diffusivity D is typically much smaller than the thermal diffusivity κ. In this case, $\varepsilon \ll 1$, and in the limit $\varepsilon \to 0$ equation (14) reduces to the simpler expression

$$F(\lambda) \approx [1 + (\Gamma C_0/T_1)]^{-1} = (C_a - C_0)/C_0 \tag{15, 15'}$$

Because F increases monotonically from 0 to 1, equation (15) has a unique solution of λ of order unity. This confirms the scaling used in equation (10) and indicates that the growth of the flat interface is controlled by solute diffusion. Note, however, that when C_0 is small (of the order of $\varepsilon^2 = D/\kappa$, with κ_s/κ_m of the order of unity) the growth is no longer controlled by solute diffusion but rather by thermal diffusion. This is indicated by the fact that in this event $\lambda = O(\varepsilon^{-1})$ and so $h = O(\kappa t)^{1/2}$. It would be interesting to carry out an experimental verification of the validity of equation (14).

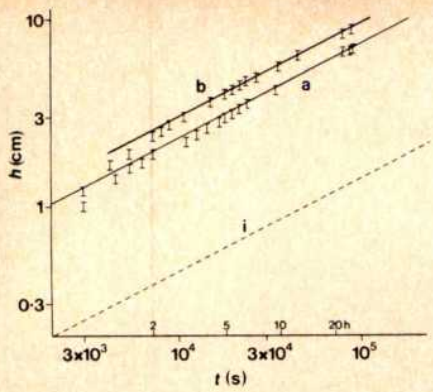

Fig. 2 Experimental and theoretical data on the height of the block as a function of time. Line a, an experiment using a Na_2CO_3 solution at eutectic composition with $T_B = -5.7$ °C, $T_\infty = 17.3$ °C. Line b is the representative experiment R with parameters in the morphologically unstable regime. Line b is the prediction of the theoretical model whereas line i is the predicted height of a flat interface at the same conditions.

Morphological instability

If the undercooling, $T_L - T_B$, is too large, solidification proceeds too quickly and the solidification interface is no longer planar. It grows in a spatially irregular manner, which will be described photographically in more detail below. The initial break-up of the planar interface is often called morphological instability. A useful physical description of the instability is discussed at length by Langer[18]. Detailed calculations[19] indicate that, on the assumption that surface tension effects are negligible, instability occurs when

$$k_s \frac{\partial T}{\partial z}(h-, t) + k_m \frac{\partial T}{\partial z}(h+, t) = -(k_s + k_m)\Gamma \frac{\partial C}{\partial z}(h+, t) \quad (16)$$

If thermal conductivity in the solid is neglected ($k_s = 0$), equation (16) becomes equivalent to the statement that instability arises whenever the predicted values of temperature and composition on the melt side of the interface lie beneath the liquidus (where the system should be partially solid). The diffusion of heat in the solid away from the interface somewhat alters the onset of instability. Surface tension does not alter equation (16) significantly in most practical situations, so we may use it as a good approximate criterion and express it in terms of our similarity solution as

$$T_0 < \Gamma C_0 \left[\frac{F(\lambda)}{1 - F(\lambda)}\right]\left[\frac{k_m + k_s}{2k_m}\frac{F(\varepsilon_m \lambda)}{\varepsilon_m^2 F(\lambda)} - 1\right] - \frac{1}{2}\frac{\rho_s}{\rho_m}\frac{L}{C_{p_m}} F(\varepsilon_m \lambda) \quad (17)$$

For given values of T_∞ and C_0 the value of T_B at which supercooling first occurs is found by solving equation (17) simultaneously with equation (14). The critical value of T_B is plotted as a function of C_0 for two values of T_∞ in Fig. 1*a*.

Experiments

We performed 12 experiments with various solutes at different values of T_B and C_0 in the tank described above. Temperatures were monitored continuously with thermistors, some of which were held fixed, and the ice block allowed to freeze around them. Occasional measurements of concentration were made by withdrawing small samples and analysing them with a hand-held refractometer. All the experiments were in the morphologically unstable regime.

The results of a representative experiment, denoted by R ($NaNO_3$; $T_B = -16.5$ °C, $T_\infty = 14.7$ °C and $C_0 = 14$ wt%), are shown in Figs 2–4. Figure 3 shows three views of the solid ice block after it was removed from the tank. The humpy form of

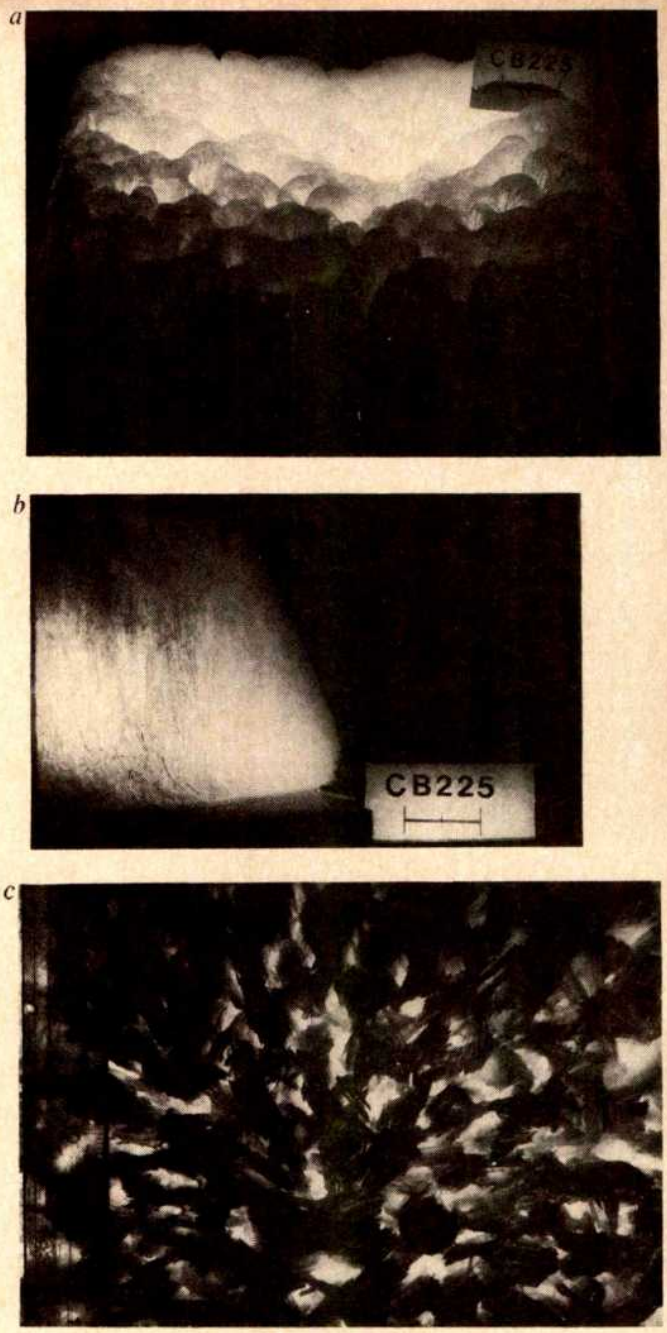

Fig. 3 *a*, An oblique view of the top of the ice block in experiment R showing the humpiness of the surface on a scale of centimetres and the finer scale 'facets' on a scale <1 mm. Horizontal scale, 2 cm long. *b*, Vertical view of the same experiment showing the lines of solid ice and the compositionally-enriched fluid. *c*, Close-up view looking vertically downwards onto the top of the block in the same experiment. Note the very fine-scale irregularities.

the surface (Fig. 3*a*) and the small-scale facets (Fig. 3*c*) depict cearly that the system is in the morphologically unstable regime. Figure 2 presents the (maximum) height of the block as a function of time and compares this with the result obtained by solving equations (10) and (14). The difference between the two indicates that the contortions of a morphologically unstable surface allows it to grow much more rapidly than if it were to remain stable. Figure 4 presents experimental and theoretical data on temperature and concentration at various times. There is considerble difference between the experimental results and those given by equations (11)–(14). The generality of this disagreement is confirmed in Fig. 5 which compares the experimental values of γ with those given by equations (11)–(14) for varying initial C_0 at fixed T_B and varying T_i at fixed C_0.

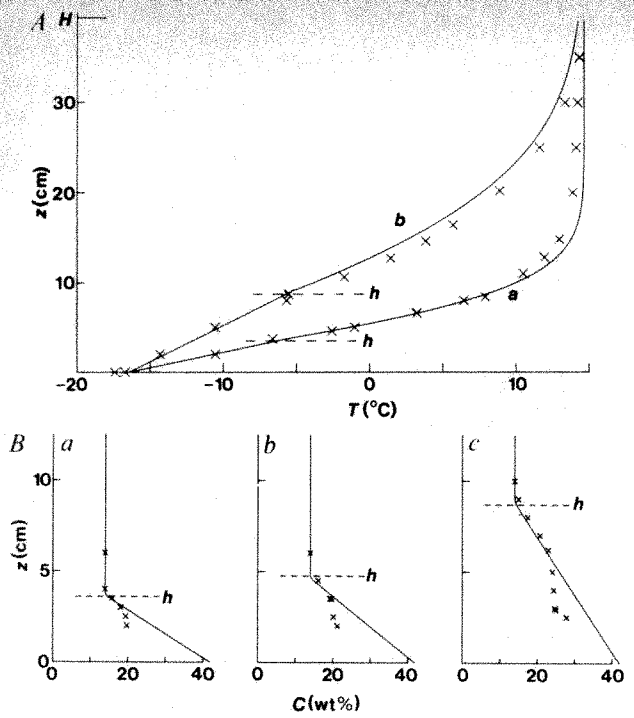

Fig. 4 *A*, Temperature profiles as a function of depth for experiment R at *a*, 3 h 40 min and *b*, 25 h 35 min. Crosses, data points; dashed lines, observed heights, h, of the ice block. Solid curves, temperatures predicted by the model of the mush. *B*, Composition profiles as a function of depth for experiment R at *a*, 3 h 20 min; *b*, 7 h 0 min; *c*, 25 h 20 min. Crosses, $NaNO_3$ concentration in fluid withdrawn by means of inserting a thin sampling tube; dashed lines, observed heights, h, of the ice block; solid curves, concentrations predicted by the model of the mush.

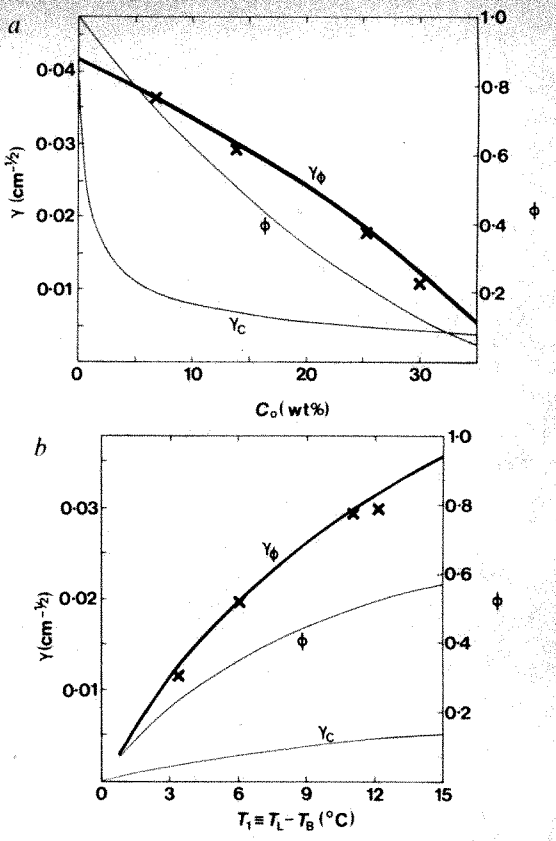

Fig. 5 *a*, Growth rate coefficient (γ) and solid fraction (ϕ) as functions of concentration for $T_B = -17\,^\circ C$ and $T_\infty = 15\,^\circ C$. The crosses are experimental values of λ. The heavy curve is the theoretical prediction obtained by solving equations (22) and (23). The light curve γ_C is the result of the model which assumes a flat interface and results in equation (14). *b*, γ and ϕ as a function of the undercooling $T_i = T_L - T_B$ for $C_0 = 14$ wt% and $T_\infty = 15\,^\circ C$.

Theoretical model

The experimental observations described here suggest that a mixed phase of solid and melt, sometimes called a mush phase, is formed when the flat interface is morphologically unstable. Equations describing the evolution of a mush have been developed previously[21,22] and similarity solutions have been found[21]. These equations relate bulk properties of the mush, averaged over a length scale larger than the typical crystal spacing. Thus, when a melt is cooled from below and crystallizes in such a way that relatively heavy fluid is released, the averaged equations predict convective stability of the interstitial fluid. The large pore size in the ice-blocks, however, suggested that compositional convection resulting in solute redistribution had occurred on a sub-pore scale. This would render the previous models inapplicable to the present situation. However, a simple predictive model of the growth of the mush (when $T_B > T_E$) can be developed, based on the controlling nature of thermal diffusion and the appropriate use of bulk conservation relationships.

We assume, for simplicity, that the densities of the solid and melt are the same. The mush extends from the cooled boundary to some position $z = h(t)$ and we assume the solid fraction, ϕ, within the mush to be constant. In reality, ϕ varies with height, but our model conserves mass only on a global scale and the constancy of ϕ is a necessary and consistent approximation. The solute concentration has uniform value C_0 throughout the melt in $z > h$ and obeys the liquidus relation described by equation (8) in the interstices of the mush. Diffusion governs the heat transfer in both the mush and the melt. Thus the thermal field is given by equations (11) and (12) with k_s and C_{p_s} replaced by the approximate expressions, whose validity are discussed by Batchelor[23]

$$\bar{k} = \phi k_s + (1-\phi)k_m \tag{18}$$

and

$$\bar{C}_p = \phi C_{p_s} + (1-\phi)C_{p_m} \tag{19}$$

and T_a replaced by $T_L(C_0)$. Global conservation of solute requires that

$$(1-\phi)\int_0^{h(t)} C\,dz = -\Gamma^{-1}(1-\phi)\int_0^{h(t)} T\,dz = h(t)C_0 \tag{20}$$

while conservation of heat at the mush/melt interface is expressed by

$$\rho L\phi\dot{h} = -k_m\frac{\partial T}{\partial z}(h+,t) + \bar{k}\frac{\partial T}{\partial z}(h-,t) \tag{21}$$

Expressions (11) and (12) are used in equations (20) and (21) to obtain

$$\phi = \left[1 + \frac{\Gamma C_0}{T_i}H(\bar{\delta}\mu)\right]^{-1} \tag{22}$$

$$L\phi = \frac{-C_{p_m}T_0}{F(\mu)} + \frac{\bar{C}_p T_i}{G(\bar{\delta}\mu)} \tag{23}$$

where

$$H(x) = [\exp(x^2) - 1]^{-1}G(x)$$

$$\bar{\delta} = (\kappa_m \rho \bar{C}_p/\bar{k})^{1/2}$$

and

$$\mu = \varepsilon_m \lambda$$

In terms of the new variable μ, the height of the block is given by

$$h = 2\mu(\kappa_m t)^{1/2} = \gamma_\phi t^{1/2} \tag{24, 24'}$$

which confirms that the growth of the block is governed by thermal diffusion. Note, alternatively, that solute diffusion is ignored in the model and correspondingly D does not appear in equations (22), (23) or (24).

Equations (22) and (23) can be solved simultaneously for ϕ and μ. The growth rate coefficient γ_ϕ is plotted as a function of C_0 for fixed T_B in Fig. 5*a* and as a function of T_B for fixed C_0 in Fig. 5*b*. The predicted growth rate is compared with the experimental results in Figs 2 and 5 and the agreement is good.

The measured temperature profiles at two different times during experiment R compare well with the predicted temperatures (Fig. 4*A*) and the measured concentration profiles agree reasonably well (Fig. 4*B*). The disagreement between the experimental data and the theoretical model at points deep in the block may result from the difficulty of inserting a sampling tube reliably to that depth and withdrawing fluid for the concentration measurement.

The validity of the theoretical relationships was tested further by conducting some experiments with different aqueous solutions. The experimental results obtained from using NaCl and NH_4Cl, which have different liquidus relationships and diffusion coefficients, again showed good agreement with the results of the theoretical model.

In conclusion, the experiments and related theory indicate that accurate predictions can be obtained from the use of simple conservation relationships when a melt whose composition is less than the eutectic is cooled from below. Variations of this same approach allow all six different cases, as mapped out in Table 1, to be solved. We plan to publish further details elsewhere.

We thank M. A. Hallworth for technical assistance and J. M. Wheeler, who helped with numerical calculations. We also thank D. R. Fearn, M. C. Flemings, E. J. Hinch, D. T. J. Hurle, R. C. Kerr, J. Lister, D. E. Loper and D. P. McKenzie for critical reading of the manuscript. The research was supported by grants from the BP Venture Research Unit and NERC. The paper was written while the authors were staff members at the 1984 WHOI Geophysical Fluid Dynamics Summer School, which operates under a NSF grant.

Cordilleria, a newly defined Canadian microcontinent

V. E. Chamberlain & R. St J. Lambert

Department of Geology, The University of Alberta, Edmonton, Alberta, Canada T6G 2E3

Palaeomagnetic data and geological field evidence indicate that most of the western Canadian cordillera lay 1,500 km south of its present position in the early Cretaceous. We suggest that this region comprised a microcontinent, termed Cordilleria, which moved on the Kula plate and collided with the craton ~100 Myr ago to form first the Mackenzie Mountains and then the Rockies.

MODELS for the evolution of the North American cordillera have proliferated since the first attempt[1] at a plate-tectonic synthesis for western North America, based on the classical fivefold division of the cordillera in British Columbia. Earlier models concentrated on the history of palaeosubduction zones; later a long list of dextral transcurrent faults of regional significance were added[2,3] and integration of the United States and Canadian portions of the jigsaw attempted[3,4]. More than 50 microplates and terranes are now recognized[5]. Palaeontological[5-10] and palaeomagnetic (refs 11-16 and E. Irving, G. J. Woodsworth and P. J. Wynne, manuscript in preparation) data clearly show the necessity for major Mesozoic transcurrent movement.

The earlier palaeomagnetic data[11-13] indicated that elements of superterrane Terrane II (ref. 17; Fig. 1) were far travelled. More recent data (refs 14, 15 and E. Irving *et al.*, in preparation) show that Quesnellia and Stikinia, elements of Terrane I (ref. 17), are also far travelled, consistent with the palaeontological evidence[7,8]. The most recent palaeomagnetic evidence (refs 15, 16 and E. Irving *et al.*, in preparation) suggests that both Terranes I and II have been displaced northwards by 14-20° of latitude and rotated clockwise through 45-50° with respect to the North American craton since the early to mid-Cretaceous. These data, from two laboratories and a wide range of Triassic, Jurassic and Cretaceous rocks, show that the southern half of British Columbia was at the present-day relative latitude of California in the early Jurassic, and was probably still there in the early to mid-Cretaceous. The movement to be accommodated between Terranes I and II and the North American craton is ~1,500 km since the mid-Cretaceous. The locus of a possible innermost (eastern) transcurrent fault on which to take up this movement has remained a problem[3,17]. Recent palaeomagnetic evidence is difficult to reconcile with the relatively small geologically observable transcurrent movements on any of the major cordilleran faults.

Transcurrent faults

The major transcurrent faults of the Canadian cordillera are shown in Fig. 2. The Denali, Queen Charlotte and Yalakom-Pasayten fault systems are too far west to accommodate movement of any elements of Terrane I. The Finlay fault system (Kutcho-Kechika-Finlay-Pinchi faults) has a total offset of ~300 km[18] and no true southern extension. The Fraser fault system can accommodate only ~150 km of early Tertiary move-

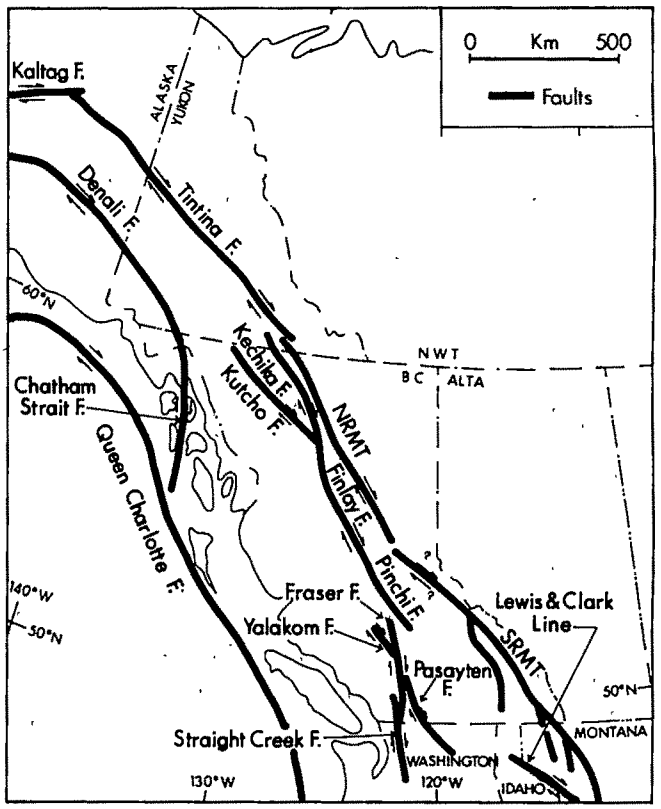

Fig. 2 Main transcurrent faults of the Canadian cordillera. None shows sufficient movement to account for all the palaeomagnetically deduced motion.

ment, which is a very small fraction of the total northward movement required of Stikinia (ref. 3 and J. W. H. Monger, personal communication). The Tintina fault and the North Rocky Mountain Trench (NRMT) fault together form a system ~1,500km long. 450 km of late Cretaceous dextral strike slip movement has been documented on the Tintina fault[19] and there may have been as much as 1,000 km of post-Palaeozoic movement on the Tintina/NRMT system (H. Gabrielse, personal communication). Thus, at least some of the northward movement of Terranes I and II may have been taken up on these faults.

Southern Rocky Mountain Trench

The Southern Rocky Mountain Trench (SRMT) is almost colinear with the Tintina and NRMT faults, although there is a discontinuity at 54° N. Together, these three faults form one of the major linear features of the Earth's crust, with a total length of ~2,500 km. The exceptional length and linear character of the SRMT have attracted many suggestions of Mesozoic or Palaeozoic transcurrent movement along it[20]. The large erosional feature (trench) suggests that it is the locus of a major fault, but its surface expression at the present-day stratigraphic level seems to result from thrust and dip-slip faulting[21]. First motion studies on a ~14-km deep, 4.8-mag earthquake just east of the SRMT near Valemount in British Columbia in 1978, however, showed dextral transcurrent as well as thrusting movement[22]. Faults frequently contain more than one type of movement[23].

Malton gneiss complex

Most stratigraphic correlations made across the SRMT are carried on thrust slices, but one major anchor seemed to be the Malton gneiss complex, which sits astride the trench at latitude 52°30'N, and has been interpreted as a single gneissic body of Proterozoic age[24]. As such, it prohibited any large-scale post-Proterozoic movement on the SRMT.

Our investigations[25–31], which included major and minor element analysis of 250 gneiss samples, have shown that the Malton gneiss complex consists of several distinct fault-bounded blocks of amphibolite facies gneiss, each of different age, geological history and petrogenesis (Fig. 3). This is supported by other authors, who describe all contacts between the gneissic basement and the Proterozoic sedimentary cover as faults, thrusts or decollements[30–32]. In particular, the Malton Block to the west of the SRMT differs from the three gneissic blocks to the east of the SRMT in age, lithology, geochemistry and isotope composition[25–29].

These fundamental differences between the gneisses east and west of the SRMT mean that the Malton gneiss complex is almost certainly more than one gneissic complex and can no longer be regarded as a constraint to transcurrent movement along the SRMT, nor as a tie, linking stratigraphy on one side of the SRMT to that on the other side. The gneisses do not correlate across the trench. For this reason, we have suggested that the term 'Malton gneiss complex' to describe the blocks east of SRMT should no longer be used[29].

Researchers who have studied the SRMT elsewhere have failed to uncover such significant differences across it, so we suggest that the Malton Block may be basement exposed in a window through the overlying late Cretaceous to Tertiary thrust sheets. Proterozoic metasediments of the Horsethief Creek Group are thrust over the Malton gneiss and across the SRMT[33]. A major decollement between the Proterozoic metasediments of the Kaza Group and the underlying Malton gneiss exposed on top of the Malton Block near the head of Robina Creek (Fig. 3) may be the basal decollement of the Rockies. The gneissic blocks east of the SRMT seem to be thrust slices, but have no obvious correlatives to the west. The reason for basement exposure at this location may be a domal upwarp at the intersection of two major structural antiforms. These are the NNW–SSE trending line of domal metamorphic core complexes[34] and the WSW–ENE trending Jasper culmination[35] that brings Precambrian rocks to the surface across the entire width of the main ranges at this latitude. The metamorphic grade of the Malton gneiss complex indicates that the surface presently

exposed has moved upwards by at least 15 km since major metamorphism.

Geophysical evidence

As a result of our observations, particularly the 'window into basement' concept, and the data demonstrating the differences across the SRMT at 52°30′N, we have reviewed the geophysical evidence for the deep structure of the crust and lithosphere on either side of the SRMT. North of ~52°N, every major geophysical parameter undergoes a significant, usually abrupt, change from one side of the SRMT to the other. South of ~52°N, these geophysical changes seem to follow a north–south line up to 150 km west of the present surface expression of the SRMT and close to the line of Kootenay Lake. The structure of the lithosphere is fundamentally different east and west of this SRMT–Kootenay Lake line, shown by seismic, gravity, magnetic, electrical conductivity and heat-flow data. The seismic activity along the SRMT is moderate, with at least one earthquake of magnitude ≥3 every 2 yr, on an average based on the past 20 yr. In 1918, there was a 6.0-mag earthquake south of the Hugh Allan Creek block, and in 1978 a 4.8-magnitude earthquake in the Bulldog Creek area[36].

The thickness of both the lithosphere and the crust change markedly across this SRMT–Kootenay Lake line, both being much thinner to the west. The crust has an average thickness of 50 km east of the SRMT[37] and 35 km west of the SRMT[38–40]. The lithosphere west of the SRMT is also 35 km thick, its base apparently coincident with the base of the crust[39,41]. The wider spacing of the magnetic anomalies east of this line[42] is consistent with the lithosphere there being thicker than to the west. The abrupt change in the trend of the magnetic anomalies as this line is crossed suggests strongly a fundamental lithospheric break[42]. Details of the magnetic anomalies such as a broadening of the eastern anomalies at the SRMT suggest a cratonic or lithospheric plate margin. The magnetically quiet zones to the west of the SRMT–Kootenay Lake line and east of the Queen Charlotte fault are also typical of plate boundaries; the magnetic zone boundaries[42] suggest that there exists a single separate plate between the Pacific plate and the Rocky Mountain Trench. This plate, we suggest, is a remnant of the Kula plate. Further evidence for the eastern boundary of this plate comes from electrical conductivity[43] and heat flow[44] measurements, both of which decrease sharply as the SRMT–Kootenay Lake line is crossed from west to east. Recently, a narrow region of exceptionally high electrical conductivity has been measured to the east of the SRMT under the main ranges of the Rocky Mountains near Valemount (D. I. Gough, in preparation). This is also a broad area of extremely high negative Bouguer anomaly (210 mGl) which is centred over the southern Canadian Rocky Mountains and decreases north-west and south-east around latitudes 54°N and 49°N, as well as decreasing to the north-east and south-west along the margins of the Rocky Mountain ranges[45].

The detailed structure of the lithosphere at lower crustal and mantle depths changes abruptly at the SRMT, shown by seismic and gravity measurements. A section across the SRMT at latitude 50°30′N, accommodating both kinds of data, shows the SRMT as a vertical fault at depth, but covered at upper crustal levels by continuous very low-density (2.76) material[46]. It also shows a high-density (3.03) lower crustal zone to the east of the SRMT and disappearing at the trench, and a high-density (3.43) upper mantle zone, present to the east, terminating abruptly at the trench. Both are replaced to the west by 3.36 density upper mantle material. This model suggests that the SRMT is a vertical fault at depth, separating lithospheres of contrasting structures. The continuous low-density material extending laterally across the vertical fault at upper crustal levels we interpret as the Rocky Mountain thrust sheets. We suggest that the lithosphere structure here may be similar to that illustrated for the closure of the Iapetus Ocean[47]. The continental crust of England is there shown being overriden by thrust sheets from Scotland, the plane of

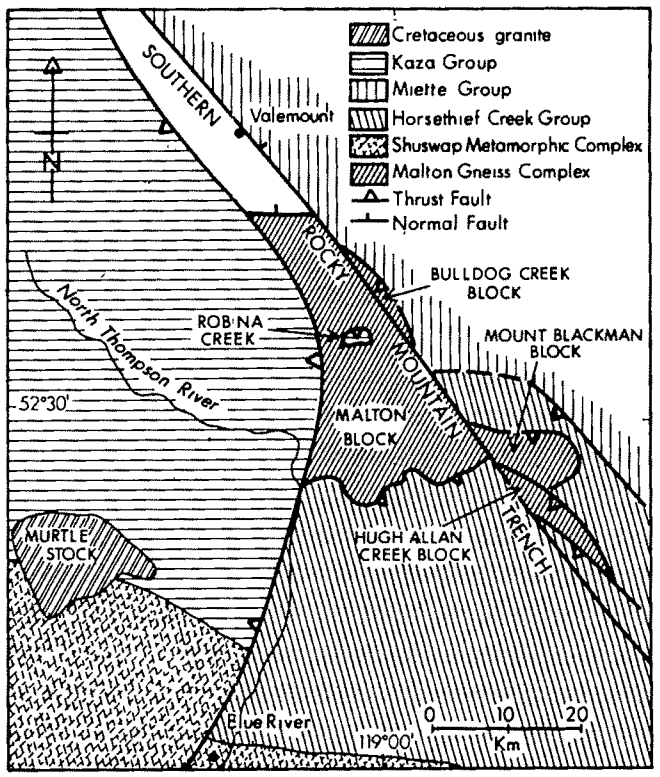

Fig. 3 The Malton gneiss complex, showing the separate blocks lying east and west of the SRMT and the overlying thrust sheets of the Proterozoic Kaza and Horsethief Creek groups.

suture dipping at a shallow angle to the north with the geophysical boundary ~100 km north of the suture in the cover rocks.

Terrane III

The Canadian cordillera has been described in terms of two superterranes, Terrane I and Terrane II, the former having amalgamated by latest Triassic–earliest Jurassic and the latter by late Jurassic[17]. The Omineca crystalline belt and the coast plutonic complex are described as two metamorphic and igneous welts that developed as a result of the collisions of these superterranes. The coast plutonic complex formed as a result of the accretion of Terrane II to Terrane I during the Cretaceous. The Omineca crystalline belt resulted from the mid-Jurassic collision of Terrane I with continental crustal rocks to the east[17].

The rocks with which Terrane I collided during the mid-Jurassic include the north-tapering wedge of Proterozoic and Phanerozoic metasediments of the Purcell, Windermere, Hamill, Lardeau and Broadview groups, the ancient gneissic rocks of the Monashee complex (basement to the Monashee decollement[48]) and possible also the Malton and Wolverine blocks. Further north, the Teslin fault is the suture zone of the mid-Jurassic collision[49], welding Terrane I to the Anvil range and Klondike schist groups.

There is no evidence of large-scale post-Jurassic north–south relative movement between Terrane I and these more easterly crustal rocks with which it collided. All the major faults in southeastern British Columbia west of the SRMT are cut by mid-Jurassic and/or Cretaceous batholiths, negating the possibility of any later major transcurrent movement. Examples occur at 125°30′ W, 55°30′ N; 120° W, 51°40′ N; 117°30′ W, 50°30′ N and 117° W, 49°30′ N. It seems that crustal rocks to which Terrane I became accreted in the mid-Jurassic have remained accreted to Terrane I ever since; it follows that the degree of north–south allochthoneity of these rocks is at least as great as that of Terrane I since the mid-Jurassic.

We propose the name 'Terrane III' for those crustal rocks which became accreted to Terrane I in the Jurassic; we show its approximate boundaries in Fig 1. In general, Terrane III is bounded to the west by Terrane I and to the east by the North American craton. Figure 1 shows the Purcell thrust as the general

eastern limit of Terrane III at the present erosion level, but it is possible that it may lie further east or west. In some locations, small klippen of Terrane I occur in Terrane III and inliers of Terrane III are found in Terrane I as a result of the mid-Jurassic collision. In places, klippen of Terranes I and III have been thrust onto rocks of the North American continent but these, we suggest, were emplaced at a later time (~100 Myr) when Terranes I and III together collided with the North American craton.

Cordilleria

As shown earlier, the available palaeomagnetic evidence indicates that the mid-Cretaceous position of Terranes I and II was 14–20° of latitude south of their present position relative to the North American craton and rotated 45–50° anticlockwise of their present orientation. The Cretaceous batholiths sampled for palaeomagnetic measurements on Terrane II are from the coast plutonic complex, the welt which formed during the accretion of Terrane II to Terrane I. As Terrane III has remained accreted to Terrane I since the Jurassic, it seems probable that Terranes I, II and III were all at least loosely amalgamated and at the latitude of present-day California in early to mid-Cretaceous times.

We propose the name 'Cordilleria' for this amalgamated super-terrane or microcontinent (Fig. 4). The southern limit of Cordilleria may be at or just south of the Lewis and Clark line in the northwestern United States, although it is possible that many or all of the suspect terranes of Oregon, Washington and California were joined formerly to Cordilleria. The northern limit of Cordilleria is not clear. Wrangellia, an element of Terrane II, was amalgamated with the Peninsular terrane of southern Alaska by mid-Jurassic times, forming the Talkeetna super-terrane[50]. The Peninsula and Kuskokwim terranes have been at the same latitude as Talkeetna since the mid-Jurassic[51] and Talkeetna was accreted to the Nixon Fork terrane and to the Yukon–Tanana terrane (an element of Terrane I) in the mid-Cretaceous[50]. This implies that a large portion of southern Alaska may have been included in the microcontinent Cordilleria.

Cretaceous subduction

Figure 5 shows one possible sequence of events for the movement of Cordilleria during the Cretaceous and here we describe a model which we believe best fits the evidence. Accurate dates are difficult to obtain because most of the available data are in the form of K–Ar ages. These tend to be minima, dating the time of final uplift and cooling of a terrane, and are also subject to problems of argon loss (and gain) and atmospheric contamination. Fitting the palaeomagnetic data into these ages causes further difficulties because palaeomagnetic blocking temperatures tend to be higher than K–Ar blocking temperatures. Further, there can be a time lag as long as 10 Myr between the onset of subduction and the K–Ar age given by a generated pluton. Present-day plate boundaries change on average every 10 Myr and every 500 km. Hence it is unreasonable to expect past plate boundaries to have been longer lasting or more continuous in type along strike.

Despite these uncertainties, it seems from the palaeomagnetic evidence that Cordilleria, relative to North America, has moved a distance of at least 1,500 km northwards since early to mid-Cretaceous. Elements of Cordilleria have rotated (possibly by internal deformation) ≤50° clockwise during the same period. Relative motion between Cordilleria and the North American craton was also affected by the westward movement of the North American plate as the North Atlantic opened.

In our model, the translation and rotation of Cordilleria is effected by seafloor spreading at the Kula–Farallon and the Kula–Pacific ridges, as well as by the northward motion of the Kula–Farallon–Pacific triple junction. Not all of the movement would have occurred along the boundaries of Cordilleria; some may have taken place within the microcontinent as the loosely

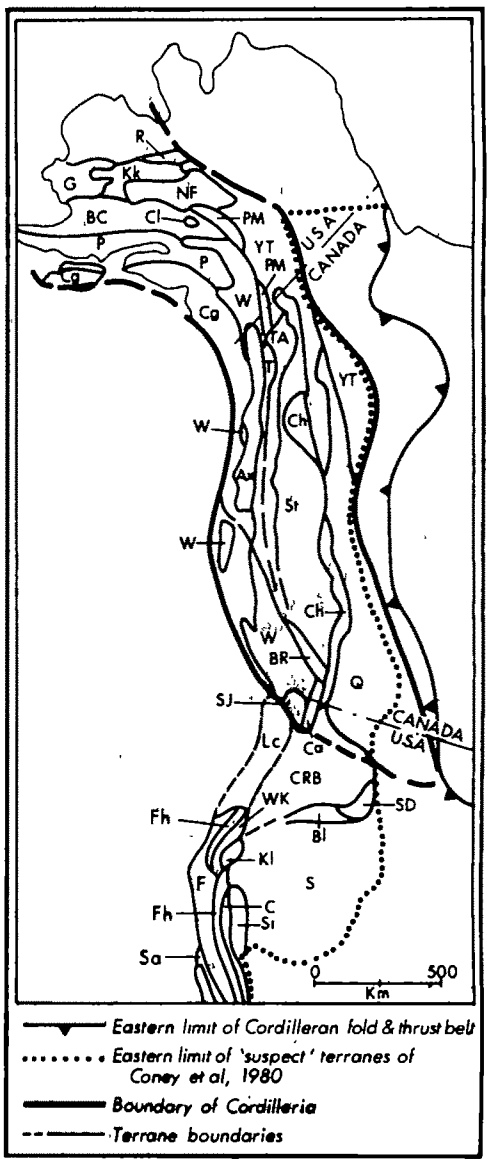

Fig. 4 The western Cordillera of North America, showing the terranes and the approximate boundaries of Cordilleria (after Coney *et al*[5] and Stone *et al*.[51]). amalgamated terranes moved relative to each other. Deformation of continental lithosphere rarely occurs on a single fault[23].

The relative motion between Cordilleria and the craton could have been taken up by transcurrent faulting, or subduction, or both. The western margin of the North American craton at this time was approximately along the line of the Tintina, NRMT and SRMT faults. Transcurrent faulting has taken place along the Tintina/NRMT fault; there is little evidence for transcurrent movement on the SRMT and no evidence of transcurrent faulting to the south. Further, the total amount of documented movement on the northern faults is insufficient to account for all of the palaeomagnetically required motion. Hence, in our model, the relative motion between Cordilleria and the North American craton is taken up largely by southward and then south-westward-dipping oblique subduction of a late Jurassic back arc

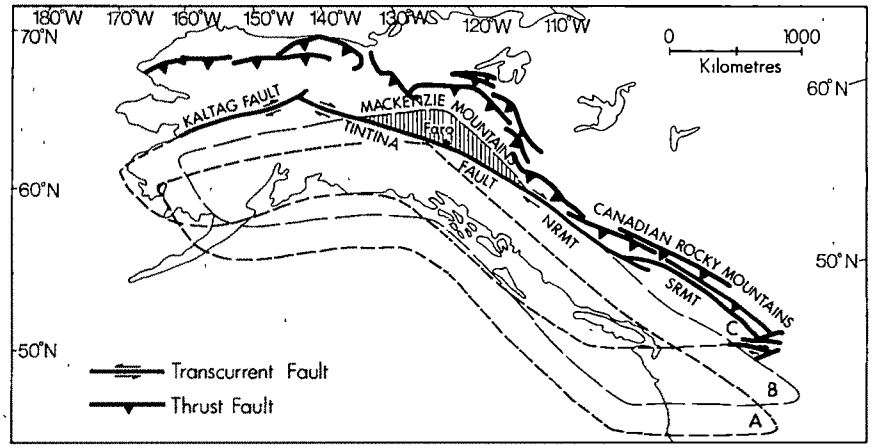

Fig. 5 Lambert equal area projection of the 'docking' of Cordilleria during the Cretaceous superimposed on the tectonic map of the present north-east Pacific (after Drummond *et al*[61]) A, B, C, Possible successive positions of the Cordilleria microcontinent as it collided with the North American craton. The shape of Cordilleria is speculative, approximating its present shape throughout, although it must have changed after collision. When in position A it was probably a looser amalgamation of Terranes I, II and III A possible protuberance which under- or overrode the North American craton at Faro is shown shaded in B. Other protuberances may also have existed, for example, one of Belt–Purcell strata (north of A) may have been thrust onto the craton when Cordilleria reached B, before transcurrent faulting moved the rest of the microcontinent into position C. Accretionary wedges forming above subduction zones along the northern and eastern margins of Cordilleria modified its shape as it moved northward. The collision at B was accompanied by tighter welding of Terranes I, II and III and a further generation of intrusives between Terranes I and II as subduction jumped westward. B represents a restoration of the 450 km of transcurrent motion on the Tintina fault and shows that the dextral transcurrent movement (B–C) would have been accompanied by an anticlockwise rotation of Cordilleria, thereby causing convergence in the Canadian Rocky Mountain region Since then, parts of Terrane II, the Pacific rim terranes and parts of southern Alaska have moved northwestward and westward on the Denali and other faults, further modifying the shape of Cordilleria.

basin beneath the northeastern margin of Cordilleria. The Cretaceous granitoids of the Omineca belt (with their relatively high strontium isotope initial ratio) could have been generated by subduction-related heating of the downgoing slab and the overlying relatively old crustal rocks of Terrane III. Volcanoes above these plutons could account for the first appearance of bentonites in the Alberta basin at ~100 Myr[52]. Subduction, besides taking up much of the palaeomagnetically required motion, would also provide a mechanism for Cretaceous (as opposed to Jurassic) thrusting and an accommodation at depth for the ~200 km of crustal shortening apparent in the southern Canadian Rocky Moutain thrust and fold belt[53]. An accretionary wedge building in the trench above this subduction zone produced the Mesozoic flysch terranes of southern Alaska[50], and further south it could have accumulated some of the $\sim 1 \times 10^6$ km^3 of material that has been eroded from the Omineca crystalline belt since the mid-Jurassic. If half of the detritus eroded during this unroofing of the Shuswap complex was later thrust onto the North American continent (under the Rocky Mountain thrust sheets) it could account for some of the ~20 km of very low-density material there[46] and for the location of the high negative Bouguer anomaly[45]. Graphite or pyritiferous black shales in this sedimentary pile could account for the very high electrical conductivity measured in this region (D. I. Gough, in preparation).

The first evidence of collision of Cordilleria with the North American craton seems to be the ~95 Myr plutons of the Mackenzie Mountains in the Yukon[54]. These plutons include S-type granites[55] consistent with generation by crustal thickening as the north-east corner of Cordilleria collided with the craton (Fig. 5, positions A–B). This is the only region where Cretaceous intrusive rocks and 'suspect' terranes occur east of the Tintina–Rocky Mountain Trench fault line. Certainly there has been obduction in this area[50] and a collision near Faro would be consistent with these facts as well as with the general shape of the Mackenzie Mountain thrust belt (Figs 5 and 6*a*).

Collision may also have occurred at about the same time along other protuberances of the Cretaceous North American craton; for example, the thrust slices of gneissic rocks east of the SRMT near Valemount and/or the Belt and Purcell groups in the northern United States (Fig. 6*b*, *c*). Extensions of Cordilleria north and south of point B in Fig. 5 may have broken off as the microcontinent collided with the North American craton at Idaho, the northern extension now forming the Belt group of the northwestern United states and the southern extension the Seven Devils arc and Blue Mountain terranes of Oregon and possibly even some of the suspect terranes of western California (Fig. 4)

The terranes of Cordilleria telescoped during collision and plate motions changed afterwards. The subduction zone jumped westward and changed polarity, initiating the late Cretaceous–early Tertiary plutonism of the coast ranges, and effecting a final suturing of Terranes I and II. Cordilleria was constrained to move northwestward and to rotate anticlockwise along the newly formed Tintina and NRMT transcurrent faults (Fig. 5, positions B–C). Transcurrent movement may have extended to the SRMT fault as well, but examination of Fig. 5 suggests that a small wedge-shaped basinal area along the SRMT would have closed slowly as Cordilleria rotated anticlockwise. This motion would rotate the southern end of the microcontinent over the craton, pushing a miogeosynclinal wedge of thrust sheets in front of it (Fig. 6*b*). Such a rotation would produce maximum (~200 km[53]) overthrusting at the southern end of the Canadian Rockies and minimum (~50 km[56]) overthrusting at the northern end. Meanwhile, the final collision of the northern end of Cordilleria with northern Alaska caused the ~200 km of overriding seen there[51] and the cataclasis of large portions of the northern Yukon–Tanana terrane. South of Cordilleria, the anticlockwise rotation may have been taken up by oblique northeasterly subduction of the oceanic part of the Kula plate under the North American craton producing the Idaho batholith (Fig. 6*c*). The radiometric ages obtained on the Idaho batholith[57] and the Valhalla dome[58] as well as the youngest ages obtained on the Proterozoic and Archaean metamorphic units along the SRMT[28] are mainly in the range 60–90 Myr. We suggest that these are intrusive or cooling ages marking the time of final suture of Cordilleria with North America, at ~80 Myr, a time when the rate of opening of the North Atlantic reached a maximum[59].

During the northward movement of Cordilleria and during and after its time of collision with the North American craton, further readjustments of the individual terranes took place; the Fraser, Denali and Queen Charlotte faults all record post-Cretaceous transcurrent movement. Evidence of late Tertiary extension is seen in normal faulting on many of the southern Cordilleria faults, including the SRMT.

The rate of northward movement of Cordilleria, relative to the North American craton, is diffiult to estimate because of the problem mentioned above of obtaining exact ages on intrusive rocks. The most likely dates are 120–110 Myr for a position ~1,500 km south of present and 105–100 Myr for position A (Fig. 5) which would require ~1,000 km of northward movement in 10–15 Myr at an average rate of 100–150 mm yr^{-1} (The remaining 500 km of northward movement were taken up by transcurrent movement in the north along the Tintina fault, and by oblique subduction and thrusting in the south.)

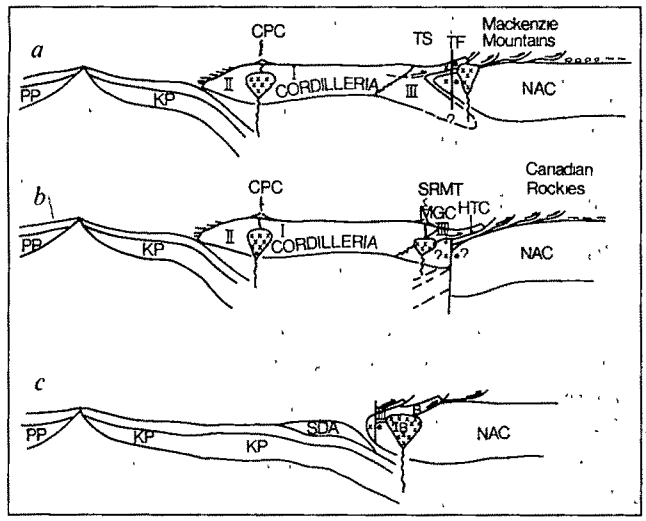

Fig. 6 Cross-sections at ~80 Myr drawn at three different latitudes. *a*, Section at the approximate latitude of Faro, Yukon, 62° N. *b*, Section at the latitude of the Malton gneiss complex near Valemount, BC 52°30′ N. *c*, Section at the approximate latitude of Salmon, Idaho 45° N. B, Belt group; CPC, coast plutonic complex; HtC, Horsethief Creek group; IB, Idaho batholith; KP, Kula plate; MGC, Malton gneiss complex; NAC, North American craton; PP, Pacific plate; SDA, Seven Devils arc; SRMT, Southern Rocky Mountain Trench; TF, Tintina fault; TS, Teslin suture. I, II and III indicate Terranes I, II and III. *a*, Westward-dipping subduction under Cordilleria during the early Cretaceous has closed a late Jurassic back arc basin between the North American craton and Cordilleria, causing a collision at ~100 Myr. The upper crust of Cordilleria was thrust onto the craton, carrying with it Terrane I ophiolites (Nisutlin, Simpson and Anvil allochthons) which had previously been obducted onto Terrane III during the mid-Jurassic collision of Terranes I and III along the Teslin suture. Crustal thickening due to the Cretaceous collision generated the S-type granites which invade the thrust sheets of the Mackenzie Mountains. After collision, motions changed, initiating dextral transcurrent movement on the Tintina fault, and subduction jumped westward, generating the granitoids of the coast plutonic complex and causing a final suturing of Terrane II to Terrane I. *b*, Early Cretaceous westward-dipping subduction which generated granitoids along the eastern edge of Cordilleria (Murtle stock at this latitude) ceased with the collision of Cordilleria and the North American craton along the line of the SRMT. The main collision at this latitude was later than in *a* because it was caused by the anticlockwise rotation of Cordilleria as it moved along the Tintina fault. During the collision, supracrustals from Cordilleria (Horsethief Creek, Kaza) were thrust onto the craton covering the suture (SRMT) between the basement blocks. Subduction jumped westward as in *a*. *c*, The first collision occurred at about the same time as in *a*, thrusting supracrustals from Cordilleria (belt group) onto the North American craton. After the collision, Cordilleria, carried on the Kula plate, moved northwestward ~450 km, rotating anticlockwise. The northwestward translation moved the southern margin of Cordilleria into a position north of Salmon; the Seven Devils arc may be a remnant of Cordilleria, broken off as the main body of the microcontinent moved northwestward. The anticlockwise rotation caused the southern end of the Kula plate to swing northeastward, the motion being taken up by its subduction under the North American plate, generating the Idaho batholith.

We propose that Cordilleria was carried northwards on the Kula plate as it moved away from the Kula–Farallon rift opening to the south. The calculated rate of movement of the Kula with respect to the American plate, obtained by extrapolating magnetic measurements back to the beginning of the Cenozoic, is 120 mm yr^{-1} northwards[60], a value quite close to the rate of movement suggested here. At the same time, the Kula–Pacific ridge was spreading and the American plate was moving westwards as the North Atlantic opened.

Conclusions

The increasing and consistent palaeomagnetic data on Mesozoic igneous rocks of south-central British Columbia places them at the latitude of California and rotated 45° anticlockwise from their present orientation. Existing theories do not include any line of suture between the Intermontane belt and the Rockies along which Mesozoic or early Tertiary northward movement and closure could have occurred. Our investigations show that the Malton gneiss complex (52°20′ N on the SRMT) is a composite feature, a window into a basement which differs on either side of the SRMT. Noting that all geophysical parameters change across the SRMT, we consider that it marks a line of weakness above a Cretaceous suture, now largely covered by the thrust sheets of the Rockies.

All the evidence can be reconciled if a newly defined microcontinent, Cordilleria, corresponding to most of British Columbia and part of the Yukon and Alaska and perhaps parts of Oregon and California, existed. This microcontinent must have lain on the Kula plate and west of a subduction zone, along which convergence occurred during the late Jurassic and early Cretaceous, closing a back-arc basin and bringing Cordilleria northward as well as towards the craton. The latter overrode the trench and was struck by Cordilleria in the South Yukon causing the Mackenzie Mountains at ~100 Myr. Closure of the remaining oceanic gap between the craton and Cordilleria caused Rocky Mountain thrusting over the next 40 Myr. In our model, the Tintina–Rocky Mountain Trench system marks the line of the former trench system and its associated dextral faults. As the convergence was oblique, however, and much of the 1,500–2,000 km displacement was taken up by subduction, equivalent amounts of transcurrent movement will not have occurred along all parts of the suture. Any transcurrent faults generated would tend to grow at one or both ends (as with the present day San Andreas) with maximum relative faulting at the point of first collision.

We thank E. Irving, D. I. Gough, W. S. McKerrow and many other colleagues for helpful discussions. Financial support was provided by the Canadian National Science and Engineering Research Council and the Federal Department of Energy Mines and Resources.

Structural analysis of murine genes containing homoeo box sequences and their expression in embryonal carcinoma cells

Anamaris M. Colberg-Poley, Stephan D. Voss, Kamal Chowdhury & Peter Gruss

Zentrum für Molekulare Biologie der Universität Heidelberg, Im Neuenheimer Feld 364, D-6900 Heidelberg, FRG

The presence of homoeo box sequences in the genomes of vertebrates has suggested that these metazoans possess the equivalent of the homoeotic genes that have a key role in regulating the development of the fruitfly Drosophila melanogaster. *We report here that a novel murine homoeo box-containing gene is expressed in embryonal carcinoma stem cells. Transcripts of the sequences that flank the homoeo box of this gene are found in these cells before and after induced differentiation, whereas a specific transcript that seems to contain the homoeo sequence is only present after differentiation.*

THE establishment of embryonal carcinoma (EC) cell lines has facilitated greatly the study of early stages in mouse embryogenesis. EC cells are derived from the pluripotent stem cells of teratocarcinomas[1] and possess many properties of ectodermal cells of the inner cell mass[2]. Advantages of these cells include the existence of various EC lines capable of differentiating into several tissue types *in vitro*, including extraembryonal endoderm, as well as their parallel use for *in vivo* studies[2]. One of these EC stem-cell lines, F9, was isolated from a transplanted male embryo[3] and expresses many antigens that are ascribed generally to embryonal carcinoma cells and mouse developing embryos[4–7]. F9 cells, unlike many other EC stem-cell lines, give rise spontaneously to differentiated cells at a very low rate[8], although differentiation can be induced by retinoic acid in the presence or absence of dibutyryl cyclic (c)AMP[9–11] or by transfection with c-*fos* proto-oncogenes[12]. The induced phenotypic alterations of retinoic acid-differentiated F9 cells are reflected in the production of markers characteristic of either visceral endoderm[10–13] or parietal endoderm[9,13–15], depending on the culture conditions. These extraembryonal tissues derive before implantation, during embryonal development, from a common stem-cell population, primitive endoderm.

Until recently the isolation of mouse genes expressed during development relied mainly on the identification of genetic information which is expressed discriminately in undifferentiated or differentiated EC cells[16,17]. In turn, we have used an alternative approach to attempt to isolate genes expressed during mouse development. This approach is based on the assumption that certain mouse developmental processes might also require the expression of homoeotic genes, similar to those of the fruitfly *Drosophila melanogaster*. To this end we screened mouse genomic information with *Drosophila* homoeo box sequences. These sequences (~200 base pairs, bp) are conserved in many of the developmental genes located in the antennapedia (ANT-C) and bithorax complexes of *Drosophila*[18–21]. These regions share a high degree of conservation not only in *Drosophila* but also with homoeo boxes found in human[22], murine[23] and *Xenopus*[24,25] DNA. Most impressive, however, is the fact that at least two of these genes have been isolated exclusively by their homology to *Drosophila* homoeo boxes and are transcribed in oocytes or during early embryogenesis in *Xenopus*[24,25]. Using two *Drosophila* probes we have isolated murine DNA sharing homology with previously described homoeo box sequences. This murine DNA detects the expression of sequences next to the homoeo box in EC stem cells as well as an additional RNA species that contains homoeo box sequences and accumulates during the differentiation of these cells. All these transcripts are encoded by the same DNA strand and are not detected in RNA isolated from macrophages.

Isolation of murine homoeo box sequences

At least eight *Eco*RI fragments of murine DNA hybridize with *Drosophila* homoeo box probes[19]. To isolate mouse homoeo box sequences, $\sim 3 \times 10^5$ members (~ 1 genome equivalent) of a mouse genomic library (gift of H. Lehrach) in λEMBL3 (ref. 26) were screened under conditions of reduced stringency using purified inserts of p903G, the 3′ region of a cDNA clone of *Antennapedia* (*Antp*)[18,27], and pFS2, the 3′ region of a genomic clone of *fushi tarazu* (*ftz*)[28]. Homologies between these two probes are confined to the sequences contained in their homoeo boxes. Of the recombinant phage screened, 10 recombinants were isolated, based on their hybridization to both probes. The DNAs of representative phage, cleaved with *Eco*RI, are shown in Fig. 1*a*. Hybridization of *ftz* and *Antp* probes to Southern blots[29] of these cleaved DNAs shows isolate-specific as well as probe-specific patterns. For example, λm5 and λm12 share two common fragments that hybridize similarly to both *Antp* and *ftz* probes, but λm6 shows hybridization of three fragments with the *ftz* probe while only two fragments hybridize to the *Antp* probe. As a control we used λm9, which is isolated by hybridization to the *ftz* probe alone. Hybridization of its *Eco*RI fragments confirms that this phage DNA hybridizes exclusively to *ftz* probe.

To determine which of the various fragments in λm5 and λm6 were hybridizing exclusively to homoeo boxes and which to flanking sequences contained within the probes, smaller fragments from *ftz* and *Antp* containing almost exclusively homoeo box sequences were hybridized with the cleaved recombinant DNA (Fig. 1*b*). λm5 and λm6 DNA showed hybridization of one and two *Eco*RI fragments, respectively, with both probes. The additional very faint band in λm5 which hybridizes with *Antp* is a partial digestion product and has not been otherwise observed. One of these recombinants, λm6, was mapped in

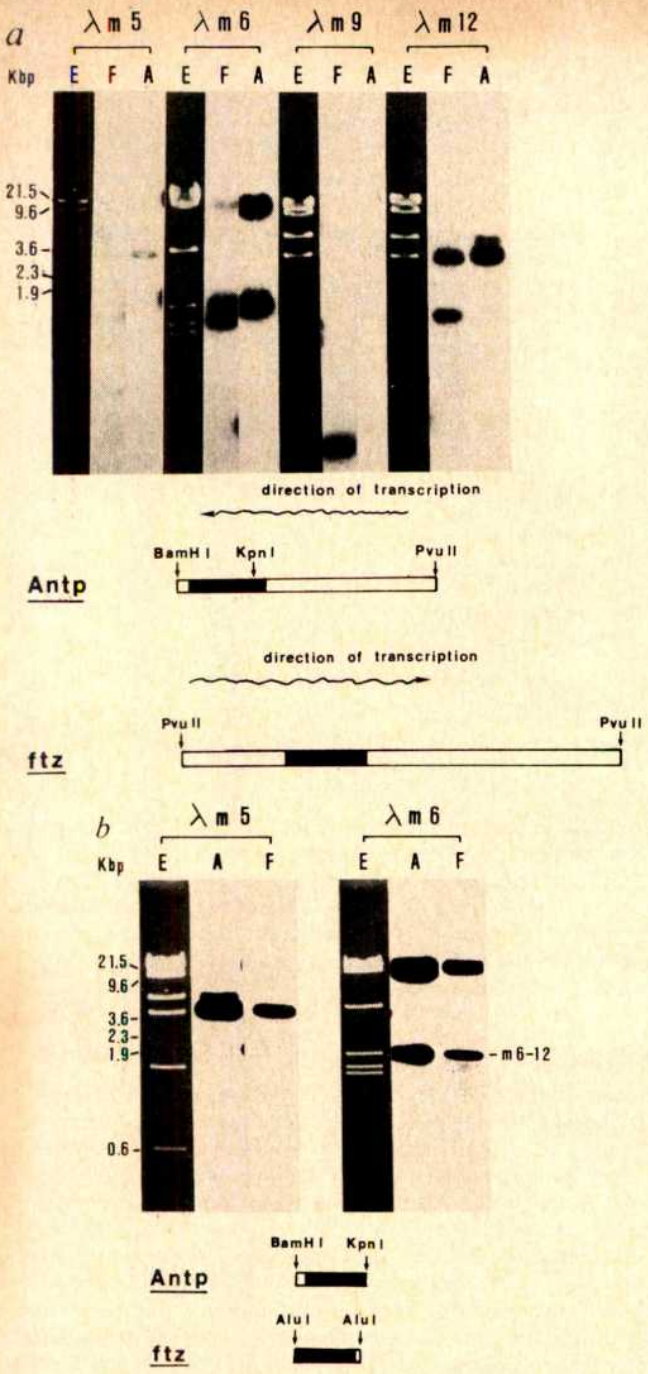

Fig. 1 Hybridization of inserts containing *Drosophila* homoeo boxes to λ mouse recombinant DNAs. *a*, Hybridization of λ mouse recombinants (λm5, 6, 9 and 12) DNAs to purified inserts of p903G (*Bam*HI/*Pvu*II) or pFS2 (*Pvu*II/*Pvu*II). Lanes E, ethidium bromide staining; F, *ftz* probe; A, *Antp* probe. *b*, Hybridization of *Drosophila* homoeo boxes to murine DNA. Phage DNAs were cleaved with *Eco*RI, separated on agarose gels (E), blotted onto nitrocellulose and hybridized with probes from *ftz* (F) or *Antp* (A). The structure of the probes and the homoeo box sequences therein (closed box) are represented beneath each panel.

Methods. Phage DNAs were isolated as described previously[40], cleaved with *Eco*RI and separated by electrophoresis in an agarose gel. Southern blots of the phage DNAs were hybridized initially with either *a*, the ^{32}P-labelled *Bam*HI/*Pvu*II fragment of p903G that contains a *Drosophila* homoeo box, then exposed, boiled in H_2O for 1 min to remove the probe and rehybridized to the homoeo box insert (*Pvu*II/*Pvu*II) of pFS2; or *b*, the nick-translated *Bam*HI/*Kpn*I insert of p903G (A) and an *Alu*I restriction fragment of pFS2 (F). The hybridizations were performed under conditions of reduced stringency (43% formamide, 5×SSC, 5×Denhardt's, 100–250 μg ml^{-1} denatured salmon sperm DNA, 50 mM Na_3PO_4, *p*H 7.0, 0.1% SDS, 37 °C) as described by McGinnis *et al.*[19] with washes at 50–55 °C in 2×SSC, 0.1% SDS.

detail and, based on overlapping restriction, hybridization patterns (Fig. 2) and subsequent sequence data, found to contain two homoeo box regions lying within 10 kilobases (kb) of one another on a contiguous stretch of murine DNA.

Murine homoeo box sequences

The hybridizing 1.9-kb *Eco*RI fragment of λm6, m6-12, was isolated subsequently and subcloned into pSP65. Finer mapping of this subcloned fragment showed that the homoeo box homologous region is confined to a 206-bp *Pvu*II/*Eco*RI fragment (Fig. 2). The sequence of this region, as well as the adjacent 300-bp *Eco*RI fragment, was obtained along both strands using chain termination[30] and chemical modification[31] techniques (Fig. 3*a*). Comparison of this sequence with the sequences of *Drosophila* (*Antp*, *ftz* and *Ubx*)[19], *Xenopus* (MM3)[25], murine (Mo-10)[23] and human (*Hu-1* and *Hu-2*)[22] homoeo boxes indicated striking, albeit varying, degrees of homology. The sequence m6 contains 83% homology to the homoeo boxes of *Hu-1* and *Hu-2*, whereas comparison with Mo-10 surprisingly showed only 78% homology; m6 is 84 and 82% homologous to *Antp* and MM3, respectively, although only 79 and 76% homologous to the other *Drosophila* homoeo boxes, *Ubx* and *ftz*, respectively.

Conceptual translation of the sequence obtained and comparison with the published homoeo box sequences of MM3, *Antp*, Mo-10, *Hu-1*, *Hu-2*, *ftz* and *Ubx* (refs 19, 22, 23, 25) are shown in Fig. 3*b*. The homologies in the amino-acid sequences were higher than those obtained with the nucleotide sequence because most nucleotide differences occur at the wobble position, indicating that the basis for the conservation of this region probably occurs at the protein level. The most homologous sequence showed the following homologies: to *Antp* (95%), *Xenopus* (93%), *Hu-2* (88%), *Hu-1* (85%), *Ubx* (85%) and *ftz* (80%). Surprisingly, the least homology in amino-acid sequence was seen with the mouse (Mo-10) homoeo box (72%). These sequences in the mouse seem to be the most divergent. We also observed at the end of the conserved homoeo box domain a succession of glutamic acid residues followed by a stop codon. As this nucleotide sequence was obtained along both strands using both sequencing methods, we are confident of its validity. A similar succession of acidic residues followed by an in-frame stop codon was observed by Müller *et al.*[25] in *Xenopus* and is also present in the sequence of *Hu-2* (ref. 22).

Expression of murine DNA

To determine whether the probe used for expression studies contained repetitive DNA, m6-12 DNA was hybridized with genomic blots of murine DNA (Fig. 4). DNA from F9 and another EC cell line, P19 (ref. 32), was cleaved with *Eco*RI, *Hin*dIII or *Kpn*I. Hybridization of m6-12 DNA with the cleaved DNAs under stringent conditions revealed hybridization to a single band in each case, showing that the sequences in m6-12 DNA detect a single-copy region. The expression of the murine DNA sequences containing homoeo box sequences and those adjacent to them was examined in three teratocarcinoma stem-cell lines. RNA was isolated from EK[33] cells and from various EC cell lines (PC13, P19 and F9 cells) and hybridized to plasmid DNA containing m6-12 (Fig. 5*a*). Two predominant bands appear in the RNAs from EK, PC13, P19 and F9 stem cells although in greatly varying amounts. The size of the larger and less abundant RNA is ~2.9 kb and the smaller RNA 1.5 kb. The quantities of poly(A$^+$) RNA from PC13, P19 and F9 blotted were corroborated by hybridization to β-actin. We observed quantitative differences in the amount of the 2.9- and 1.5-kb RNAs in the various stem-cell lines. There is 3–6 times more of the 1.5-kb messenger RNA in the F9 cells than in PC13 and P19 cells and ~12 times more of this transcript in F9 cells than in EK cells. The larger 2.9-kb mRNA is also more abundant in F9 cells compared with P19, PC13 and EK cells (an ~3.5 to 5-fold difference). These RNAs are ~10 times less abundant in F9 cells than β-actin RNA. These differences were normalized

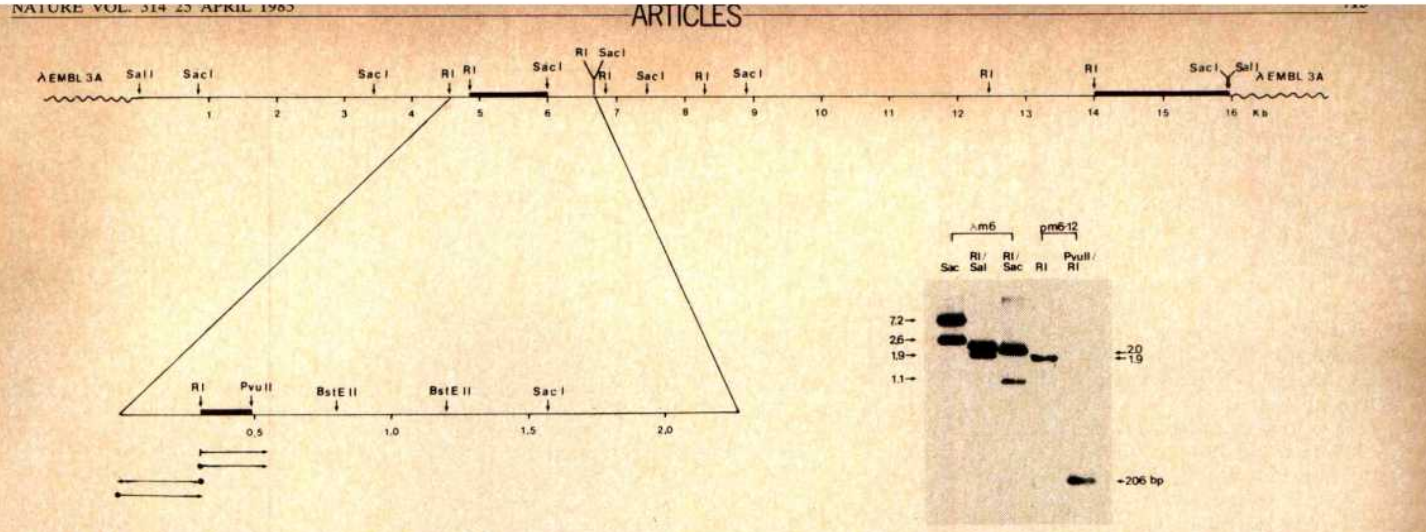

Fig. 2 Restriction mapping and subcloning of fragments contained in λ clone m6. The recombinant phage DNA contains *Mbo*I partially digested (~16 kb) murine liver DNA cloned into *Bam*HI sites of λEMBL3A (ref. 26). The figure localizes the homoeo box-homologous regions to 1.3-kb *Eco*RI/*Sac*I and 2.0-kb *Eco*RI/*Sal*I fragments (closed boxes).

Methods. Hybridizations used the 600-bp *Antp* cDNA fragment (see Fig. 1*a*) as probe. A 1.9-kb *Eco*RI fragment containing the 1.3-kb *Sac*I/*Eco*RI homoeo box-hybridizing fragment was subcloned into pSP65 to give pm6-12. The homoeo box homology was further confined in pm6-12 to a 206-bp *Pvu*II/*Eco*RI subfragment (see insert). The *Bst*EII/*Eco*RI fragment containing the *Pvu*II site was purified subsequently, 3′ end labelled at the *Eco*RI site with Klenow fragment and sequenced according to the method of Maxam and Gilbert[31]. This sequence was confirmed along the opposite strand by the method of Sanger *et al.*[30] using a subclone of the 1.3-kb *Sac*I/*Eco*RI fragment, mp11/m6-12. The adjacent 300-bp *Eco*RI fragment was cloned in both orientations in M13mp11 to obtain sequence information along both strands.

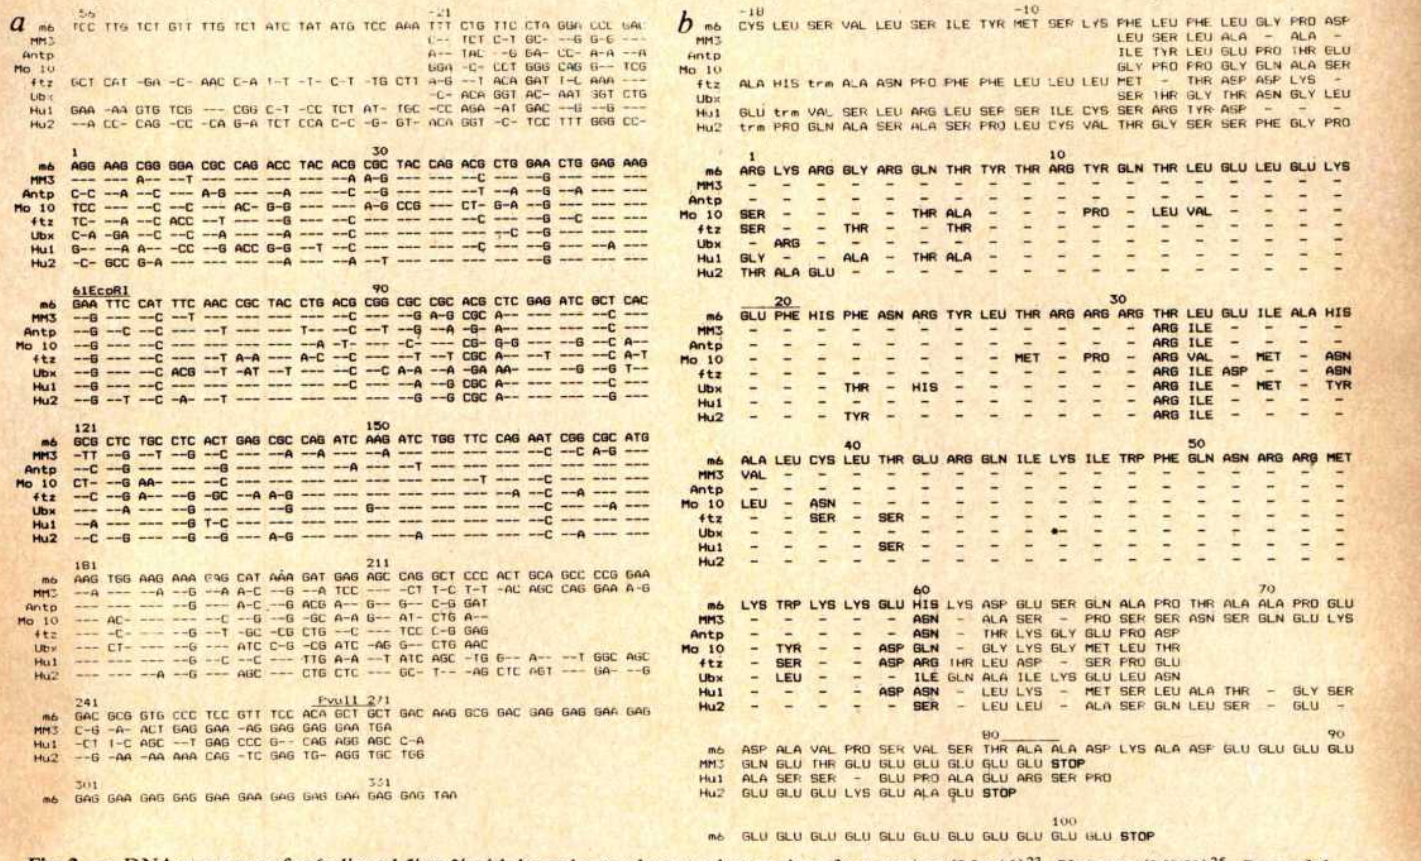

Fig. 3 *a*, DNA sequence of m6 aligned 5′ to 3′ with homologous homoeo box regions from mouse (Mo-10)[23], *Xenopus* (MM3)[25], *Drosophila* (*Antp*, *ftz*, *Ubx*)[19] and human (*Hu-1* and *Hu-2*)[22] DNA. Only those nucleotides that differ from m6 are shown. Conserved nucleotides are indicated by -. *b*, Conceptual translation of the conserved homologous open reading frame in m6 and its comparison with other homoeo box amino-acid domains. Comparison is with amino acids −18 to 83 as numbered in refs 19, 22, 23 and 25. Only non-homologous amino acids are shown directly; conserved amino acids are indicated by -; the asterisk indicates a change in the published amino-acid sequence of *Ubx* (W. Gehring, personal communication).

relative to the amount of β-actin mRNA in each sample as evidenced by hybridization of the blot with a β-actin probe.

To look for RNA encoding potential regulatory proteins induced during differentiation, F9 cells were differentiated by treatment with 5×10^{-7} M retinoic acid and 10^{-3} M dibutyryl cAMP. Poly(A)$^+$ RNA was obtained at different times during the first 24 h of differentiation and after 5 days of treatment (Fig. 5*b*). At 17 h, at least one new RNA (2.4 kb) appeared, although longer exposures of the blot show the presence of an additional low-level 3.2-kb transcript that shows a marginal induction on differentiation of the F9 cells (data not shown). The other two transcripts present in undifferentiated F9 cells, the 1.5- and 2.9-kb mRNAs, remain present during the differenti-

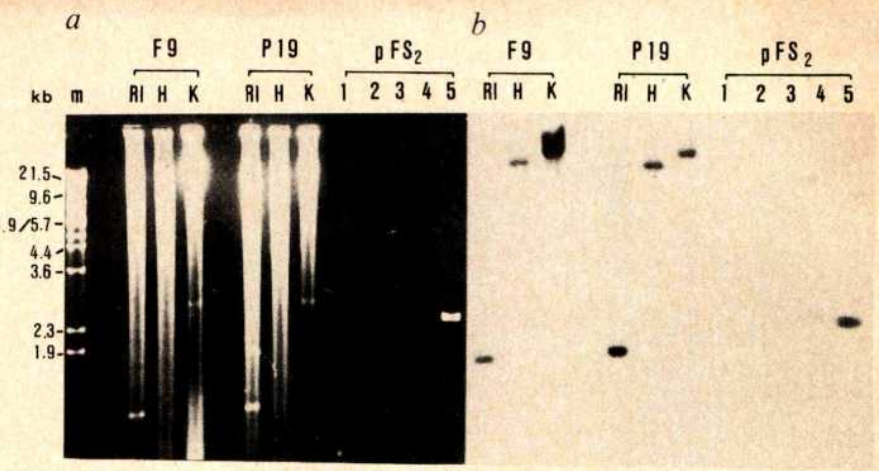

Fig. 4 Hybridization of murine DNA containing a homoeo box (m6-12) to mouse genomic DNA from F9 and P19 cells. *a*, Ethidium bromide staining of cellular DNA. Cell DNA was isolated by treatment of cells with lysis buffer (50 mM Tris-HCl, 20 mM EDTA, 100 mM NaCl, *p*H 7.5) and digestion with proteinase K (50 μg ml^{-1}) for 16–24 h. DNAs were purified by phenol extraction and ethanol precipitation. DNAs were cleaved with *Eco*RI (RI), *Hin*dIII (H) or *Kpn*I (K) and separated on a 0.7% agarose gel (*b*). A Southern blot of DNA in gel *a* was hybridized with nick-translated (m6-12) DNA (1.9 kb *Eco*RI fragment). Various concentrations of uncleaved pFS2 DNA (1, 0.01 ng; 2, 0.1 ng; 3, 1 ng; 4, 10 ng; 5, 100 ng) were included. Hybridization, under stringent conditions, used the same buffer as in ref. 19, with 50% formamide. The blots were washed at least four times in 0.1 × SSC and 0.1% SDS at 52 °C for 15 min each.

ation of the F9 cells, although one of these (2.9 kb) shows a slight increase (~twofold) during this period.

To determine whether these mRNAs were present 5 days after induction of differentiation, poly(A$^+$) RNA from F9 cells treated with retinoic acid and dibutyryl cAMP for short (< 24 h) and long (5 days) periods were compared. All the transcripts that hybridized with m6-12 at 17 and 24 h (3.2, 2.9, 2.4 and 1.5 kb) were also present at 5 days, although in apparently reduced quantities (1.5–6 times less) compared with the earlier times. Each value was once again standardized by comparison with the amount of poly(A$^+$) RNA blotted for each sample, as determined by β-actin hybridization.

The presence of either homoeo box or flanking sequences in each of these predominant RNA species was examined by hybridization with subfragments contained in the 1.9-kb *Eco*RI fragment, m6-12, which had been used in the initial Northern analyses. Blots of poly(A$^+$) RNAs from stem and retinoic acid- and dibutyryl cAMP-differentiated (24 h) F9 cells were hybridized with either the *Eco*RI/*Pvu*II 1.7-kb fragment containing flanking sequences (Fig. 6*a*) or the 0.206-kb *Pvu*II/*Eco*RI fragment that largely contains the murine homoeo box sequences (Fig. 6*b*). The flanking sequences hybridize with all of the transcripts previously seen in F9 cells at 17 h, 24 h and 5 days after treatment with retinoic acid and dibutyryl cAMP. The probe containing the homoeo box, however, hybridizes strongly to only one of these mRNAs, the 2.4-kb mRNA, which is induced shortly after differentiation. In addition, there is a weak hybridization of this probe to the most abundant of these mRNAs, the 1.5-kb species. To determine whether the observed transcripts are encoded by the same or the opposite strand of m6-12 DNA, single-stranded probes were used (Fig. 6*c*). Hybridization of the noncoding (panel 1) and coding (panel 2) strands showed that all the RNAs detected by the m6-12 (panel 3) probe are complementary to the coding strand and are thus transcribed from the strand encoding the conceptually translated homoeo box open reading frame.

Conclusions

One of the central aims of developmental biology is to understand the molecular details of the mechanisms governing the precise control of differentiation processes. Although little is known about the regulatory mechanisms of mammalian development, the wealth of genetic information[34] and the availability of EC stem-cell lines led us to choose these as model systems for the study of mammalian development. Differentiation of F9 stem cells is possible either by treatment with retinoic acid or by transfection with an oncogene (c-*fos*). It remains unclear, however, whether this results from a direct or indirect action of the inducer.

Discovery of common homoeo box sequences in many of the developmental genes in *Drosophila* and developmentally regulated genes of *Xenopus* led us to isolate analogous genes and to study their products in murine EC cells. So far, we have isolated seven mouse phage recombinants that contain homology to the *Drosophila* homoeo boxes and show different restriction patterns. Detailed examination of one λm clone (λm6) indicated the presence of at least two homoeo box regions.

Analysis of the nucleotide sequence of one of these regions revealed an extremely well-conserved sequence of 180 bp. Approximately 84% homology to *Antp* can be detected at the nucleotide sequence level. The amino-acid sequences of these conceptually translated proteins are even more highly conserved (95% homology). Amino-acid homology with proteins of known structure (cro and *c*I) suggests that the most conserved region includes an α-helical domain (ref. 20 and W. Gehring, personal communication). Interestingly, the most homology was to the homeo boxes of the *Antp* gene of *Drosophila*, *Xenopus* (MM3) and the human genome, whereas the least homology was to the murine Mo-10 gene. Whether this structural resemblance to the *Antp* gene, MM3 and the human genes also reflects a functional resemblance remains to be determined. Clearly, the m6 homoeo box region is different from the Mo-10 gene. Further comparison of MM3 with m6 reveals conservation of both the homoeo box and a stretch of glutamic acid residues, which lies outside the homoeo box and at the carboxy-terminus of the putative protein. Although the functional significance of this acidic domain remains necessarily speculative, such domains exist in the non-histone nucleosomal proteins HMG1 and HMG2 (ref. 35) and in a neurofilament protein, NF-M (ref. 36).

Before using m6-12 sequences as a probe for Northern analyses, they were characterized by hybridization to genomic blots of murine DNA. Although the m6-12 DNA contains homoeo box sequences present in several copies in the murine genome, Southern analysis showed that it hybridized to unique DNA. The inability of this probe, which primarily contains flanking sequences, to detect other homoeo boxes in the murine genome, may have resulted from the very stringent conditions used in the Southern hybridizations in contrast to the non-stringent conditions of the library screening. Furthermore, possible differences in the sequences of murine homoeo boxes (compare m6 and Mo-10 sequence homology) and the specific activity of homoeo box sequences contained in the probe (< 7%) could have precluded their detection.

The probe containing murine homoeo box sequences was used for studies of RNA expression in EK and various stem cells. Surprisingly, F9 stem cells show a strong expression of two differently sized classes of RNA. The same RNA classes can also be seen in EK, PC13 and P19 cells, although in reduced amounts. One interpretation of these results is that F9 cells are already pre-determined and do not represent a true stem cell any longer. Similar conclusions have been drawn by Adamson and Hogan[37] on the basis of low-level synthesis of transferrin

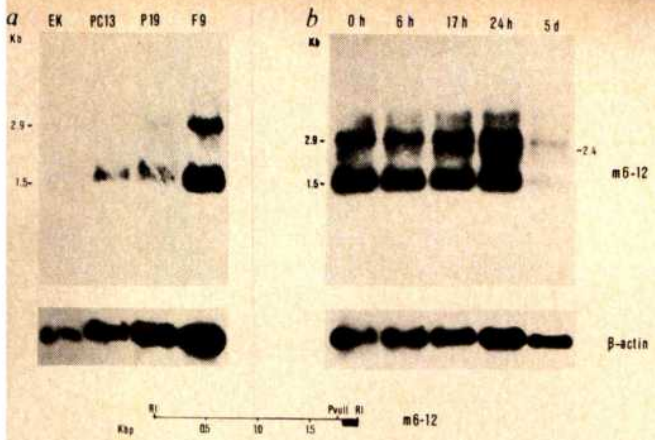

Fig. 5 Hybridization of m6-12 DNA with mRNA from various teratocarcinoma stem cells and differentiated F9 cells. *a*, Poly(A^+) RNAs from EK, PC13, P19 and F9 cells were hybridized with ^{32}P-labelled pm6-12 DNA. *b*, RNA obtained from F9 cells treated with retinoic acid (5×10^{-7} M) and dibutyryl cAMP (10^{-3} M) for 6, 17, 24 h and every other day for 5 days were hybridized with ^{32}P-labelled pm6-12 DNA. Autoradiograms of control hybridizations of each Northern blot (*a* and *b*) with ^{32}P-β-actin DNA are shown below each corresponding panel. Differences in the intensities of the bands were quantitated by densitometer scanning. The structure of the m6-12 insert in the probe is shown at the bottom of the figure; the solid box represents the homoeo box sequence.

Methods. RNA samples were isolated using the guanidinium thiocyanate method of Chirgwin *et al.*[41] and purified by centrifugation through a 5.7 M CsCl, 25 mM sodium acetate, *p*H 5.0 cushion. Poly(A^+) RNAs were obtained from each group by retention on oligo(dT) columns, then 5 μg of poly(A^+) RNAs was placed in each well and electrophoresed through formaldehyde–agarose gels using 3.7% formaldehyde in MOPS buffer (20 mM morpholinopropane sulphonic acid, 50 mM sodium acetate, 10 mM EDTA *p*H 7.0). RNAs were blotted onto Gene Screen Plus and hybridized to nick-translated plasmid containing m6-12 DNA (lower portion of the figure) and then to β-actin DNA. Briefly, Northern blots were hybridized with ^{32}P-DNA in 50% formamide, 1.0 M NaCl, 1% SDS and 100 μg ml^{-1} denatured salmon sperm DNA. Blots were washed twice in 2×SSC at room temperature, twice in 2×SSC, 1% SDS at 60°C, and twice in 0.1×SSC at room temperature.

and expression of epidermal growth factor receptors in F9 stem cells, markers which are not usually present on other stem cells.

We were also interested to determine whether differentiation of F9 cells is accompanied by the differential expression of murine genes. RNA produced by F9 cells at various times after differentiation into parietal endoderm showed the early appearance of an additional transcript (2.4 kb) that hybridized with both the homoeo box and flanking sequences contained in the m6-12 probe. The transcripts present in F9 stem cells and those which increase so rapidly during the first 24 h of differentiation persist well into the time when F9 cells express markers of differentiated cells (5 days), although in decreased quantities compared with another transcript such as β-actin. RNA from macrophage, a terminally differentiated cell type, did not accumulate detectable amounts of these mRNAs (data not shown). To establish the relationship between the detected RNAs, the 206-bp *Pvu*II/*Eco*RI fragment containing the murine homoeo box and an additional 90 bp was hybridized with mRNAs from F9 stem and differentiated (24 h) cells and the 2.4-kb mRNA was detected, suggesting that the transcript contains homoeo box sequences. Although there is also a weak hybridization to the most abundant mRNA (1.5 kb; data not shown), the intensity of this hybridization, compared with that seen with the 2.4-kb mRNA, suggests that not all of the probe sequences are present in this transcript. This hybridization could result either from homology with the 206-bp probe or from a minor contamination of this probe with the larger 1.7-kb

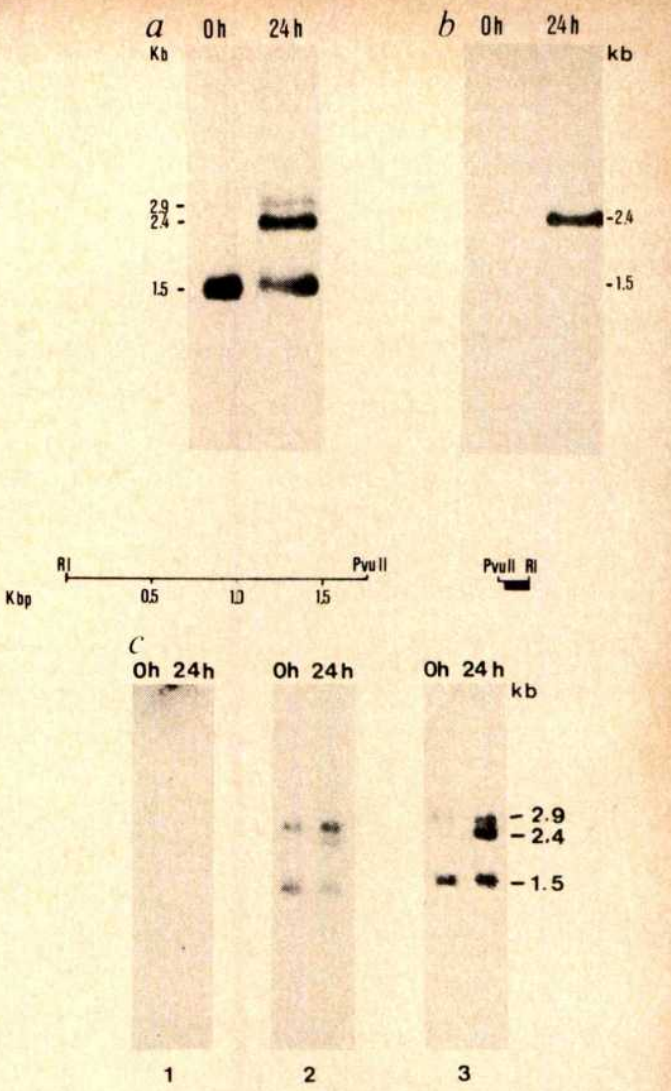

Fig. 6 Hybridization of the flanking (*a*) and homoeo box (*b*) sequences contained in m6-12 DNA and (*c*) single-stranded M13 m6-12 DNA probes to stem-cell (0 h) and differentiated F9 (24 h) cellular RNA. The structures of the probes are shown at the bottom of the figure (solid box represents homoeo box sequences).

Methods. Poly(A^+) RNAs from F9 stem cells and those treated with retinoic acid and dibutyryl cAMP for 24 h were obtained as described in Fig. 5 legend. Samples (5 μg) were separated by electrophoresis in formaldehyde–agarose gels, blotted onto Gene Screen Plus and hybridized to either the nick-translated 1.7-kb *Eco*RI/*Pvu*II fragment (*a*), the 206-bp *Pvu*II/*Eco*RI fragment (*b*) from m6-12 or to the noncoding (1) or coding (2) strands of M13mp10 or mp11 recombinants (*c*) containing the 1.3-kb *Sac*I/*Eco*RI insert from m6-12. As a control, nick-translated pm6-12 (3) was also hybridized to F9 stem-cell (0 h) and differentiated F9 cell (24 h) RNA (*c*). The M13 single-stranded DNA probes were labelled by incorporation of ^{32}P-dCTP using primer extension, denatured in 0.1 M NaOH and electrophoresed in alkali agarose gels. Labelled single strands were recovered by electroelution.

*Pvu*II/*Eco*RI fragment. Because the larger *Pvu*II/*Eco*RI fragment containing the remaining m6-12 sequences hybridizes with all of the transcripts previously seen following differentiation, the 3.2-, 2.9-, 2.4- and 1.5-kb mRNAs presumably all contain these flanking sequences. It is likely, however, that although these mRNAs are transcribed from the strand of DNA that encodes the homoeo box protein open reading frame and map closely on the mouse genome, only the 2.4-kb mRNA contains homoeo box sequences. All of the transcripts that hybridize to the pm6-12 probe were still detected after washing the Northern blots under very stringent conditions (0.1×SSC at 60° C, data not shown).

In attempts to determine whether the induced 2.4-kb mRNA is specific for the production of parietal endoderm, we have performed experiments using several cell types: F9 cells differentiated by treatment with retinoic acid and aggregation into visceral endoderm, P19 cells differentiated into myoblasts[38,39] and mouse embryos isolated at different stages of development. Experiments with retinoic acid-treated F9 cells (visceral endoderm) showed a 2.4-kb mRNA on differentiation similar to that present in parietal endoderm. P19 cells differentiated into myoblasts, as well as mouse embryonic and extra-embryonic tissues, also express mRNAs that hybridize to m6-12 sequences.

We intend to use the different EC cells as model systems to study the role of various homoeotic genes in the differentiation of these cells.

We thank W. McGinnis and W. Gehring for the homoeo box plasmids, H. Lehrach for the murine library, B. Paterson for the β-actin plasmid, C. Stewart and E. Wagner for EK poly(A$^+$) RNA and critical reading of the manuscript and M. Kessel and W. Franke for helpful discussions. We also thank E. Vosshans-Bosbach for technical assistance and R. Franklin for typing the manuscript. Are galaxies more strongly correlated than clusters?

Alexander S. Szalay* & David N. Schramm

The University of Chicago, Chicago, Illinois 60637, USA and Fermilab, Batavia, Illinois 60510, USA

One of the most powerful tools used in attempts to understand the structure of the Universe is the correlation function $\xi(r)$, the excess probability over random that there are two objects separated by a distance r. In particular, distributions of galaxies and of clusters of galaxies have been investigated using this parameter. Here we show that if the amplitudes of the cluster–cluster correlation function is made dimensionless, systematic changes with cluster richness vanish, implying scale invariance in the clustering process. The dimensionless galaxy–galaxy correlation seems stronger, implying gravitational enhancement on smaller scales.

It has been established[1] that for distances out to 10 Mpc, the galaxy distribution has a power-law correlation of the form $\xi_{gg}(r) = \alpha_{gg}(hr)^{-1.8}$, where h is the Hubble constant in units of 100 km s^{-1} Mpc^{-1}. Recently , the spatial correlation function of Abell clusters has been determined directly[2,3], following earlier work on the angular correlations[4]. It was noted that rich ($R \geq 1$) clusters of galaxies correlate with the same power law as galaxies, but with a significantly greater amplitude, $\alpha_{cc} = 18\alpha_{gg}$, which is even higher for richer ($R \geq 2$) clusters. Clusters poorer than most Abell clusters were identified in the Lick catalogue by a numerical algorithm[5]. The correlations had the same slope and the amplitude was between that of galaxies and that of the Abell clusters, in agreement with the richness trend (see Table 1).

An attempt to explain the behaviour of α_{cc} has been made by Kaiser[6] applying the statistics of rare events. If the density perturbations are described by a random gaussian field and the regions where clusters form correspond to densities higher than a certain threshold, the correlation function of the points above the 'clipping level' is a constant factor times the correlation function of all the points. By filtering out from the initial power spectrum the scales smaller than clusters and choosing the appropriate threshold, it was possible to match both the number density and enhanced correlations of the Abell clusters. To explain the factor of 20 in α_{cc} the clusters have to be $\geq 3\sigma$ points. In this picture $\xi_{cc}(r)$ will have the same functional form as the galaxy autocorrelations. The model may have some difficulties here, because ξ_{gg} seems to be negative at 20-Mpc radii, but ξ_{cc} is positive out to at least 100 Mpc.

The r.m.s. peculiar velocities and the correlation amplitude of the mass are related; both originate from the power spectrum of perturbations. The clusters cannot represent the true mass autocorrelations in the universe, because then we would expect to see enormous (a few thousand kilometres per second) peculiar velocities for the clusters, which does not seem to be the case.

Whenever similar systems of different scales are compared, it is better to use dimensionless quantities. The correlation amplitude α_{cc} is dimensional; it is $\xi_{cc}(r)$ at a distance $hr = 1$ Mpc. It can be made dimensionless by using an intrinsic unit of length for each sample of different richness. The natural length that appears in these point catalogues is the mean separation L, determined by the density $n = L^{-3}$. This mean separation is indeed intrinsic because there is a unique one-to-one correspondence between richness and the value of L, which is because the richer samples are always subsets of the poorer catalogue. Therefore, labelling the different richness selections by L, the density of each sample is one, and the value of the correlation function at L (expressing distance in units of L) is also dimensionless: $\beta(L) = \xi(L) = \alpha(L)L^{-1.8}$.

* Permanent address: Eotvos University, Budapest, Hungary.

Table 1 The dimensional correlation amplitude $\alpha(L)$, compared with the dimensionless $\beta(L)=\alpha(L)L^{-1.8}$ for groups and clusters of increasing richness

Sample	$\alpha(L)$	n	L	$\beta(L)$
Galaxies	20	8.0×10^{-3}	5	1.10
Schectman	180	3.6×10^{-5}	30	0.39
BS $R\geq1$	360	6.0×10^{-6}	55	0.27
BS $R\geq2$	1,080	2.0×10^{-6}	80	0.41

n, The comoving spatial density in Mpc^{-3}; $L=n^{-1/3}$, the mean separation in Mpc. The spatial density of galaxies is given in ref. 15.

The constant slope in the power law behaviour of $\xi(r)$ indicates scale invariance of the process responsible for galaxy formation. In the case of galaxies, the typical distances are a few Mpc, whereas for clusters the same law holds to distances >50 Mpc. If galaxy formation were completely scale invariant, one would expect that all dimensionless correlation amplitudes would be equal.

Figure 1 is a plot of the dimensionless amplitude $\beta(L)$ for all the samples, including the different richness classes of Bahcall and Soneira[2]. Note that $\beta(L)$ for galaxies is 1.1, a factor of three higher than for the cluster samples, which are all consistent with 0.35. As far as clusters are concerned, the scale invariance seems to hold. The correlation amplitudes of the cluster catalogues are fairly well known, but their densities are less certain. Because L and thus $\beta(L)$ depend on the density, we plotted conservative error limits on Fig. 1 corresponding to densities 1.5 times above and below the quoted value. Thus compared, galaxies are more strongly correlated than clusters, the opposite conclusion to that obtained by comparing $\alpha(L)$.

The relative constancy of $\beta(L)$ can be understood in general terms as a signature of scale invariance. If there is a nonlinear process (besides gravity) modulating galaxy formation and this process is scale invariant, the created pattern will have a single power law correlation function[7], $\xi(r)=\beta(r/L)^{D-3}$, the slope of which would be related to the geometry of the pattern, namely to its fractional (or 'fractal') dimension D. This $\xi(r)$ will have the correct scaling property. Thus, to explain the observed slope, a fractal dimension of $D=1.2$ is required, but we do not know yet what physical process can generate the correct D. (We discuss several possibilities below.)

Small-scale gravitational clustering may break the scale invariance and increase the dimensionless correlation amplitude for galaxies. In one extreme case, we can approximate this process by assuming that the pattern imposed on the galaxy distribution is uncorrelated with the gravitational motion. Then the observed correlations are a superposition of the gravitational and fractal correlations, with $\xi_{frac}(r)=0.35(r/L)^{-1.8}$, which is scale invariant, and $\xi_{grav}(r)$ a flat function of r out to ~10 Mpc, independent of L. ξ_{grav} Is the Fourier transform of the power spectrum: $1+\xi_{obs}(r)=[1+\xi_{grav}(r)][1+\xi_{frac}(r)]$. If $\xi_{grav}(0)\approx3$, then we approximately reproduce the observed factor of three in $\beta(L)$.

In the other extreme the process is the nonlinear 'clipping' of the gravitationally induced overdensities[6], in which case the 'fractal' and the gravitational perturbations are fully correlated. Kaiser has also found a limited scale invariance for that particular model. If the selection is simply the result of a threshold in the initial perturbations, which are otherwise scale invariant, the resulting regions, the so-called 'excursion sets', will have a scale-invariant geometry and will be fractals[8]. If the universe is dominated by 'cold' dark matter, the fluctuation spectrum has an asymptotic form of k^{-3}, where k is the wavenumber. The larger galaxy correlations in this case can be attributed to effects of nonlinear gravitational clustering on small scales. From comparisons of the low r.m.s. galaxy velocities and the high correlation function of galaxies, it seems that such a 'bias' is useful[9].

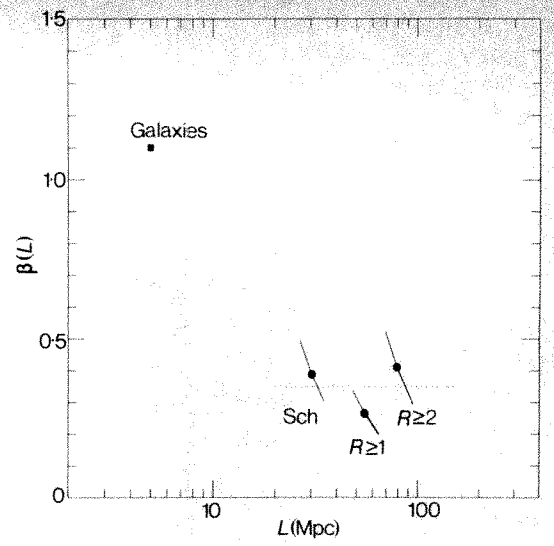

Fig. 1 The dimensionless correlation amplitude $\beta(L)$ is shown as a function of the mean separation L. Note that all three cluster catalogues are consistent with 0.35 (dashed line), whereas the galaxy amplitude is 1.1. The error-bars in the cluster data represent a factor of 1.5 up/down uncertainty in the density.

All these mechanisms have the advantage of increasing the galaxy correlations while leaving the velocities intact.

Schulman and Seiden[10] have already suggested similarities between condensed matter physics and galaxy formation. Their conclusion, from simple analogies with short range interaction spin systems, was that only fractals with $D\sim2$ can be obtained.

Gas dynamical processes are bound to occur at some level during galaxy formation. The formation and explosion of first generation Pop III stars[11,12] could have major consequences for the entire galaxy formation scenario. Although the energies available in each explosion are insufficiently large, percolation may occur, creating random structures of 'infinite' length that can produce the required behaviour.

Another possibility is relativistic strings[13,14], which have attracted much attention recently. If present, they may create patterns with a fractal dimension close to unity.

In conclusion, we propose that galaxy and cluster correlation functions be compared in dimensionless units. The dynamic range of correlation amplitudes has been reduced from 50 to 3. All cluster correlations are consistent with the same scale-invariant amplitude. That in those units galaxies are more strongly clustered may be because of small-scale gravitational clustering, whereas the slope and the dimensionless amplitude may reflect a scale invariant process responsible for creating luminous galaxies in certain regions of the universe.

A new non-thermal galactic radio source with a possible binary system

E. Fürst*, W. Reich*, P. Reich*, Y. Sofue† & T. Handa†

* Max-Planck-Institut für Radioastronomie, Auf dem Hügel 69, D-5300 Bonn 1, FRG
† Nobeyama Radio Observatory, Tokyo Astronomical Observatory, University of Tokyo, Minamisaku, Nagano 384-13, Japan

Helfand and Becker[1] recently discussed the unusual filamentary appearance of the galactic radio sources G357.7–0.1 and G5.3–1.0, both of which had originally been classified as supernova remnants (SNR$_s$)[2,3], and proposed that these sources belong to a new class of non-thermal radio sources that originate in accreting binary systems containing a neutron star or a black hole. Becker and Helfand[4] have pointed out that other galactic sources may be identified as members of this class; we report here our claim that a new non-thermal galactic object (G18.95−1.1), detected in the recently published 2.695-GHz galactic plane survey[5], is a possible candidate. That the integrated flux density spectral index $\alpha = -0.4$ ($S_\nu \sim \nu^\alpha$) and the polarization is ≈2.5% at 4.75 GHz, proves the non-thermal nature of the new source; morphologically, a classification of this object as a SNR seems impossible. G18.95−1.1 consists of various arcs all pointing towards a central radio peak; we suggest that the object is a binary system containing a compact component, located at or close to this radio peak, accelerating electrons to relativistic energies—observed in the arcs by the synchrotron emission of the accelerating electrons.

The source G18.95−1.1 has subsequently been observed at 1.42 GHz and 4.75 GHz with the Effelsberg 100-m telescope and at 10 GHz with the Nobeyama 45-m dish. The 4.75-GHz map is shown in Fig. 1 and the spectrum is plotted in Fig. 2. Both the spectral index and the polarization reveal the non-thermal nature of G18.95−1.1.

How do we classify this object? The peak radio intensity is close to the centre of the object and shows a bar-like structure with peaks near each end of the bar (Fig. 1). Even the highest available angular resolution does not allow separation of any compact source from the diffuse emission. The grey-scale radiograph in Fig. 3 allows the determination of the source structure in much greater detail. From this presentation it is apparent that G18.95−1.1 consists of various arcs pointing towards the radio peak slightly off-centre to the north-east. Clearly, the morphology of G18.95−1.1 defies any classification as a SNR and also contradicts the general appearance of radio galaxies. Its arcs may be of similar origin to the filaments in G357.7−0.1 discussed by Helfand and Becker[1]. We therefore suggest a binary system containing a compact component as the source of G18.95−1.1. This possible centre of activity should be expected to be located in the central bar, perhaps at or close to the peak emission north-east of the centre. If the central location of this source is not the result of projectional effects, the velocity of the binary system relative to the filamentary structure is low, or the source is much younger than G357.7−0.1 and G5.3−1.0.

The estimation of source parameters (for example, age, distance) is hindered by the insufficient data available. We suggest that deep optical observations (no corresponding emission could be found in the Palomar plates) and a search for X-ray emission be made. At radio wavelengths, more sensitive polarization

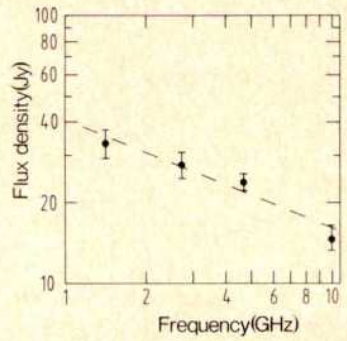

Fig. 2 The radio spectrum of G18.95−1.1. The integrated flux densities are: $S(1.42\ \text{GHz}) = 32.9$ Jy, $S(2.695\ \text{GHz}) = 27.4$ Jy, $S(4.75\ \text{GHz}) = 23.8$ Jy and $S(10\ \text{GHz}) = 14.6$ Jy; the typical error is 10%. The mean flux density spectral index $\alpha = -0.4$. There may be a steepening of the spectrum from $\alpha = -0.4$, in the inner part near the radio peak, to $\alpha = -0.5$ at the outer arcs, but the accuracy of the spectral index is 0.2. The errors are mainly attributable to the uncertainty in the estimation of the base levels.

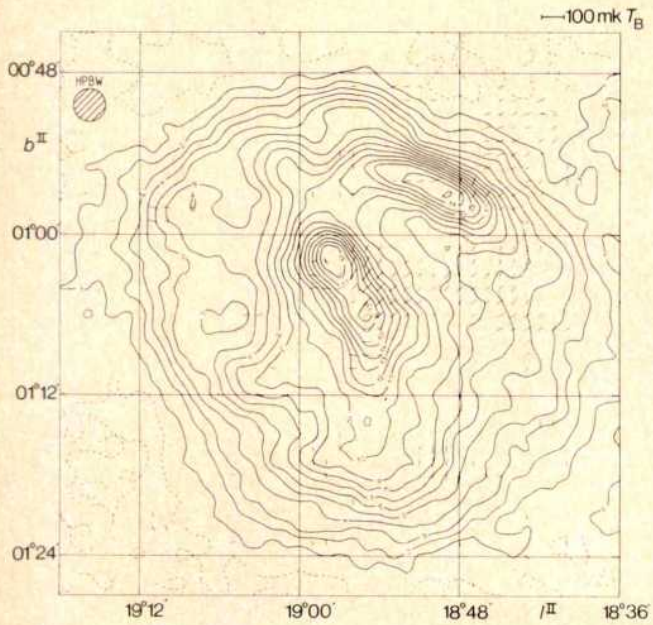

Fig. 1 4.75-GHz map of G18.95−1.1. Contour steps are 50 mK brightness temperature T_B. The angular resolution is 2.4 arc min. Superposed are the linear polarization intensity E-vectors. The integrated polarization percentage is 2.5%.

Fig. 3 The grey-scale map of G18.95−1.1.

measurements together with improved angular resolution (possibly using the Very Large Array) and a search for a pulsar will certainly help to understand the nature of G18.95−1.1. If our assumption of a binary system as the source of G18.95−1.1 is confirmed, this object will provide important information on the interaction of binary systems with the surrounding interstellar medium.

We thank Professors R. Wielebinski and W. Kundt and Dr W. Sieber for helpful comments.

A higher limit to the mean galaxy mass allowed by gravitational lens image distortion

Steven Phillipps

Department of Applied Mathematics and Astronomy, University College, PO Box 78, Cardiff CF1 1XL, UK

Tyson *et al.*[1], in a recent discussion of the gravitational lens distortion, by foreground galaxies, of the images of distant ('background') galaxies, claim that their non-detection of this effect implies a low mean mass for the foreground galaxies. The effect they sought is a change in the coherent ellipticity, that is, the ratio of the angular diameters orthogonal and parallel to the separation vector to the foreground galaxy. Using samples of galaxies in different ranges of magnitude to represent the 'foreground' ($19 < J < 21.5$) and 'background' ($22.5 < J < 23.5$) galaxies, they found no significant effect and therefore deduced a 2σ upper limit to the mean mass of the foreground galaxies of only $2.8\times10^{11}\ H^{-1}\ M_\odot$ out to a radius of $80\ H^{-1}$ kpc (where H is Hubble's constant in units of 100 km s^{-1} Mpc^{-1}). The corresponding mass-to-light ratio and the known luminosity density of the Universe then requires that the mass density in the form of galaxies is $\Omega_{gal} < 0.03$, which is in marked contrast to the values $\Omega_{gal} \sim 0.2$ obtained by various dynamical arguments, namely, the rotation curves of individual galaxies, the virial equation applied to groups and clusters and the cosmic virial theorem[2–5]. I show here that, by including the effect of galaxy clustering, the limit on Ω_{gal} is indeed raised to $\Omega_{gal} \leqslant 0.2$, in accordance with the dynamical determinations.

Tyson *et al.*[1] noted that for the two magnitude ranges they used, there should be little overlap in the distances of their two sets of galaxies, and substantiated this by Monte Carlo experiments using a Schechter[6] luminosity function. They claimed therefore that almost all observed pairs should be a genuine background–foreground pair (the lensing effect is insignificant if the two galaxies are close together). However, this step is invalid if galaxy clustering is taken into account, because for any observed pair, what we really require is the conditional probability of finding a 'background' (that is, faint) galaxy at a particular distance given the presence of the foreground galaxy, since this becomes significantly confused by nearby clustered low-luminosity galaxies. It is easy to see that this has a substantial effect by considering the standard form for the galaxy autocorrelation function[7], $\xi(s) = (s/r_0)^{-\gamma}$, with index $\gamma = 1.8$ and scale length $r_0 \approx 5\ H^{-1}$ Mpc. Even at the maximum pair separation used by Tyson *et al.*, corresponding to $220\ H^{-1}$ kpc at the mean distance $D = 720\ H^{-1}$ Mpc of the foreground galaxies, the clustering increases the number of expected neighbours by factors of several hundred relative to that for a random distribution.

More exactly, we can integrate the correlation function to show that the number of galaxies per unit solid angle at separation θ from a given foreground galaxy, distance D from the observer, will be[8]

$$N' = N + D^2\Phi(M)G(\gamma)r_0^\gamma(\theta D)^{1-\gamma}$$

where N is the mean surface density, Φ is the integral luminosity function and $G = 3.678$ for $\gamma = 1.8$. Now, from Tyson *et al.*, we find the mean background density to be 5,670 galaxies per deg^2 or $N = 1.86\times10^7$ rad^{-2}. Also, with the previously specified values of D, G, r_0 and γ and taking[9] $\Phi \approx 0.05\ H^3$ Mpc^{-3} (in this context Φ is the number density of galaxies in the magnitude range $-16.5 \geqslant M_B - 5\log H \geqslant -17.5$ corresponding to $22.5 < J < 23.5$ at $D = 720\ H^{-1}$ Mpc), the second term on the right-hand side has the value $1.7\times10^8\ \theta_s^{-0.8}$, where θ_s is the separation in arc seconds.

In other words, the fraction of genuine background–foreground pairs that are able to show a measurable lensing effect is only $1/(1+9\ \theta_s^{-0.8})$ so that the mean distortion will be diluted by a factor ranging from 4.0 at $\theta = 4$ arc s to 1.5 at $\theta = 40$ arc s. (Note that the ratio will be the same even if there is a bias against detecting close pairs, because of the presence of the bright foreground galaxy, thus reducing the apparent clustering.) As the effect sought is greatest at small separations, this obviously greatly limits the power of the test. When the dilution factor is included, even the most massive model considered by Tyson *et al.* (outer radius $190\ H^{-1}$ kpc, equivalent circular velocity 300 km s^{-1}, that is, mass $\approx 2.1\ H^{-1}\times10^{12}\ M_\odot$) is within 2.5σ of the observed points for all except one of the bins in θ. It may therefore be prudent, at present, to take a conservative upper limit of $\sim 2\times10^{12}\ H^{-1}\ M_\odot$ for the mass of a mean foreground galaxy, which raises the limit on the density parameter to $\Omega_{gal} \leqslant 0.2$. We note also that if the clustered galaxies are preferentially aligned[10], then the situation is even worse than we have assumed and almost any density parameter will be allowed, because this effect will work in opposition to the lens effect that causes an orthogonal elongation.

I thank Professors M. J. Disney and B. F. Schutz and Drs E. Balbinski, M. G. Edmunds, A. H. Nelson and A. P. Whitworth for valuable discussions.

Synthesis of ethylene and ethane by partial oxidation of methane over lithium-doped magnesium oxide

Tomoyasu Ito & Jack H. Lunsford

Department of Chemistry, Texas A&M University, College Station, Texas 77843, USA

The partial oxidation of methane into more useful chemicals such as methanol, ethylene and benzene has been investigated extensively, although yields for these products have been poor[1–4]. Moreover, in several of these processes the required oxidant is N_2O rather than O_2. Recent work[5] in our laboratory has demon-

Table 1 Results for the partial oxidation of methane at 720 °C over Li/MgO

	Partial pressure (torr)								
	Reactants		Products				Conversion†	C_2 selectivity	C_2 yield
Run no	CH_4	O_2	CO_2	CO	C_2H_4	C_2H_6	%	%	%
1	59	29	11.2	0.0	3.5	2.2	37.8	50.3	19.0
2	58	36	13.7	0.2	3.7	2.1	42.8	45.4	19.4
3	89	29	11.1	0.0	4.6	3.1	29.1	58.1	16.9
4	218	117	51.2	1.5	15.4	7.4	37.5	46.5	17.4

In earlier runs (not listed), Li/MgO was used at 770 °C. Values for C_2 selectivity and C_2 yield were based on the amount of methane that had reacted. C_2 yield is defined as the product of conversion and C_2 selectivity.

strated that lithium-doped magnesium oxide (Li/MgO) in the presence of O_2 has high activity for abstracting H from CH_4 to form $\cdot CH_3$ radicals. This suggests that C_2H_6 and C_2H_4 (C_2 compounds) are produced by a coupling between two gaseous $\cdot CH_3$ radicals formed on this catalyst. We report here our success in converting CH_4 to C_2 compounds in high yields in conventional catalytic conditions.

Powder catalysts of Li/MgO, containing 3 and 7 wt% Li, were prepared from Li_2CO_3 and MgO[5] and then activated at 465 °C in an oxygen flow. The catalytic experiments were performed at 1 atm in a conventional flow reactor of the type described previously[4]. A reacting gas mixture of CH_4, O_2 and He (a diluent) was introduced at a flow rate of 0.83 ml s^{-1}. All of the gases were analysed by gas chromatography except HCHO, which was analysed by a titration technique[4].

High yields for the C_2 compounds were attained when the ratio of O_2 to CH_4 in a reactant mixture was ~0.5. The results, which were obtained at 720 °C over 4 g of 7% Li/MgO, are summarized in Table 1. Besides C_2H_4, C_2H_6, CO_2 and CO, CH_3OH and HCHO also were produced, but in only trace amounts. By comparison, the conversion of CH_4 was 0.2% at 720 °C in the same experimental conditions except for the absence of the catalyst. Pure MgO catalyst (1 g), prepared by the same method as Li/MgO but without Li_2CO_3, produced the C_2 compounds with a low selectivity of 6% at a conversion level of 17% at 700 °C.

A yield of 19% for the C_2 compounds was obtained with 50.3% selectivity at 37.8% conversion (run 1), which is considerably better than results reported in the literature for other metal oxide catalysts[1,3]. Almost equal amounts of CH_4 and O_2 reacted with each other, and most of the O_2 was consumed during the reaction in these experimental conditions. By feeding a reactant gas mixture containing O_2 in a higher ratio than that of run 1, we could attain a higher conversion of CH_4, but the selectivity for the C_2 compounds decreased (run 2). In contrast, a reactant mixture of the lower O_2/CH_4 ratio gave a better C_2 selectivity but a poorer conversion (run 3). Run 4 shows that a good yield of C_2 was obtained even at a higher partial pressure of the reactants if the O_2/CH_4 ratio was kept at ~0.5. Although C_2H_4 is the main C_2 compound over Li/MgO, C_2H_6 is also produced in considerable amounts. From the practical viewpoint, it is desirable that C_2H_6 is converted into C_2H_4 and the technology for this process is available.

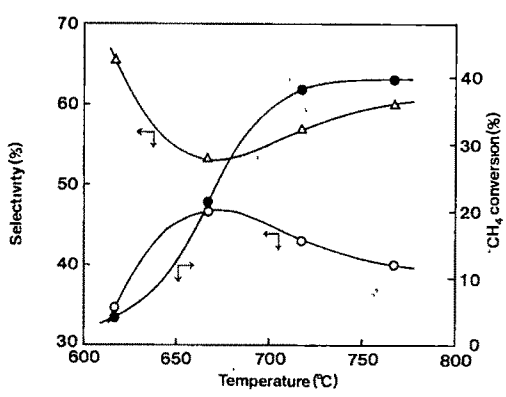

Fig. 1 Effect of the reaction temperature on the partial oxidation of methane. A reactant mixture containing 291 torr of CH_4 and 155 torr of O_2 was fed over 4 g of 3 wt% Li/MgO. Selectivities ○, C_2 compounds; △, CO plus CO_2, ●, per cent conversion.

Figure 1 shows effects of reaction temperature on the CH_4 conversion and the selectivities, which were measured over 4 g of 3% Li/MgO. This reaction system is unusual in that the selectivity for C_2 compounds increases as the CH_4 conversion increases up to a temperature of 670 °C. In most heterogeneous oxidation catalysis, the selective oxidation decreases with increasing conversion. The phenomenon in Fig. 1 may be understood in terms of two primary reaction pathways for the $\cdot CH_3$ radicals; they may either couple to form C_2H_6 (ref. 6) or they may react with the oxide surface to form surface methoxide ions that ultimately result in the production of CO and CO_2 (ref. 7). The former channel is second order with respect to $[\cdot CH_3]$ and is thus favoured at high temperatures where more $\cdot CH_3$ radicals are produced. One cannot, of course, rule out the possibility that part of the CO and CO_2 is formed by a homogeneous reaction between $\cdot CH_3$ and O_2. The C_2H_6 may be converted to C_2H_4, also through alkyl radicals, but further oxidation to CO and CO_2 seems to be retarded below 670 °C in the presence of CH_4.

The $\cdot CH_3$ radicals are believed to be formed at (Li^+O^-) centres on MgO (ref. 5) which have been observed in Li-doped MgO single crystals[8] and more recently in the sample used in these experiments[5]. Gas phase and surface studies have shown that O^- ions efficiently abstract H· from CH_4 (refs 7, 9). The Li/MgO catalyst does not contain ions having variable oxidation states or transition metals; thus, it is a new type of catalyst for the activation of methane.

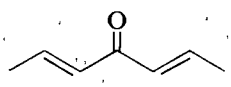
Highly conducting acetylene–CO copolymers and limitations of the soliton model



James C. W. Chien, G. N. Babu & J. A. Hirsch

Departments of Chemistry and of Polymer Science and Engineering, Materials Research Laboratories, University of Massachusetts, Amherst, Massachusetts 01003, USA

There is much scientific and technological interest in conductive polymers, of which polyacetylene is the simplest and best example, and in the mechanism of carrier transport. *Trans*-$[CH]_x$ with C_{2h} symmetry is said[1–4] to have an electronically degenerate ground state with very slight alternation of backbone bond lengths, that is, a high degree of conjugation. Radicals or radical ions in the chain are referred to as soliton[5,6] and polaron[7] excitations with moving domains, but these rigorous concepts are quite restrictive and exclusive. For instance, moving-domain excitations cannot exist in *cis*-$[CH]_x$ because much energy is required for the interconversion of *cis*-transoid and *trans*-cisoid structures. However, many physical and spectroscopic properties of undoped and doped *trans*-$[CH]_x$ have been explained by these models[8]. An intersoliton electron-hopping model had been proposed for carrier transport in lightly doped *trans*-$[CH]_x$[9]. Our purpose here is to test the general validity of the soliton/polaron models. Our present results cast strong doubts on the relevance of these theoretical models to carrier transport in conductive polymers, thereby allowing a search for possible new conductive polymers that is free of the constraints imposed by these models.

Copolymerizations of acetylene and CO were initiated by the $Ti(OBu)_4/4AlEt_3$ catalyst at −78 and 25 °C for 18–24 h at monomer feed ratios (C_2H_2/CO) of 4/1, 2/1 and 1/1 to give copolymers of composition 95/5, 90/10 and 87/13, respectively. The number-average relative molecular masses are ~3,900 ± 300 and 970 for copolymers obtained at −78 and 25 °C, respectively, as determined by quenching with tritiated methanol[10–12].

We have the following evidence that copolymers were obtained: (1) Elemental analysis (Table 1). (2) Radioassay of ^{14}CO-containing copolymers. (3) Magic angle spinning ^{13}C-nuclear magnetic resonance (NMR) showed a carbonyl resonance at 178 p.p.m.[13] of the correct intensity. (4) Two carbonyl bands at 1,670 and 1,720 cm^{-1} attributable[14] to the C=O vibrations in

and $-CH=CH=\overset{O}{\overset{\|}{C}}-H$

respectively; the latter was probably formed on quenching of Ti—C(=O)—P with methanol. (5) Copolymers formed directly on electron microscope grids[15] are devoid of the characteristic fibrillar morphology of polyacetylene[16] and are completely amorphous according to electron diffraction[17,18]. (6) The *cis*-content in the pristine copolymer decreases markedly with the increase of CO monomer; probably, the initially formed *cis*-transoid structures[19] are more easily isomerized to the *trans* structure because of the presence of the single bonds in the —C(=O)— units and the absence of crystallinity. (7) Thermogravimetric analysis of copolymers showed a progressively larger weight loss at lower temperatures with increasing amount of CO, with the weight loss approximately equal to the CO in the copolymer. (8) Pyrolysis GC–MS of the copolymers produced almost the same products as that of polyacetylene[20] but with CO and some CO_2 and H_2O. (9) Treatment of the copolymer with protonic acid greatly reduces the intensities of the 178 p.p.m. ^{13}C-NMR resonance and the infrared carbonyl bands as expected for facile protonation of carbonyl groups activated by adjacent π systems. Lastly, (10) the copolymer films have a dull coppery colour on the side facing the reactor wall, but the other side has various shiny green colours that depend on the monomer feed ratio and which are different from those of polyacetylene—indicative of the wider band gap for the copolymer than for polyacetylene.

The key magnetic and transport properties of undoped poly(acetylene-*co*-CO) are summarized in Table 2. For simplicity, we will refer to the samples poly(95acetylene-*co*-5CO), poly(90acetylene-*co*-10CO) and poly(87acetylene-*co*-13CO) as

p-**C**	0.04	129	0.04	161	+18

* Sample composition as in Table 1. † *y*, Mol. dopant per repeat unit ‡ *p*, Pristine AC-copolymers.

A, B and C, respectively. The pristine AC-copolymers have room temperature (RT) peak-to-peak linewidths ΔH_{pp} for their unpaired-spin EPR that are comparable to, but smaller than, for *cis*-$[CH]_x$; the differential is larger for copolymers with more CO content. Their linewidths increased to 6 G at 134 K, consistent with low diffusivity of the unpaired spins. Thermal isomerization of the AC-copolymers greatly reduces the number of unpaired spins to only 10^{-4}–10^{-3} of the number in *trans*-$[CH]_x$, but the isomers have comparable RT EPR linewidth and motional narrowing. In sample C, there is on the average one —C(=O)— unit separating segments containing about six $+CH=CH+$ units, the length of which corresponds to the estimated domain widths for soliton[21] and polaron[7]. The EPR of *trans*-AC-copolymers shows about the same motional narrowing as in *trans*-$[CH]_x$. This is either because local processes cause line narrowing or because the —C(=O)— unit does not present a significant barrier to moving domain. Furthermore, the spin-lattice and spin-spin relaxation times are within a factor of two for the two sets of polymers—pristine AC-copolymers and *cis*-$[CH]_x$ and isomerized AC-copolymers and *trans*-$[CH]_x$. Finally, the undoped AC-copolymers all have conductivity σ_{RT} and thermopower coefficient S_{RT} comparable to the corresponding undoped $[CH]_x$.

The values of σ_{RT} for iodine-doped pristine AC-copolymers are either comparable to, or greater than, those for iodine-doped *cis*-$[CH]_x$ (Table 3, column 3). The σ_{RT} values of AsF_5-doped AC-copolymers are one-half to one-fourth those of similarly doped *cis*-$[CH]_x$. The S_{RT} values, indicative of the intrinsic conductivity of the material, are almost the same for AsF_5-doped AC-copolymers and *cis*-$[CH]_x$ (Table 3, column 6).

In conclusion, the AC-copolymers do not have the molecular and supermolecular structures required for soliton and/or polaron excitations; yet those magnetic and transport properties heretofore said to be uniquely belonging to *trans*-$[CH]_x$ and attributed to soliton and/or polaron are manifest in the copolymers. The fact that an extremely low unpaired spin concentration in isomerized AC-copolymers occurs without any loss in conductivity, unlike in *trans*-$[CH]_x$, invalidates any transport mechanism invoking the participation of neutral soliton. Of course, the situation is very complicated for the heavily doped polymers and much more research has to be done before elucidating further the conduction mechanism. The significance of this work is that the results obviate the rigid and restrictive present theoretical framework for conducting polymers and open up possibilities for creative designing and synthesis of new polymers. Furthermore, it eliminates the need to force the soliton/polaron concept on poly(pyrrole), poly(*p*-phenylene vinylene), poly(*p*-phenylene), poly(phenylene sulphide), poly(*p*-aniline) and others that do not have electronic ground-state degeneracy. A conductive polymer needs to have only short conjugated segments to facilitate the redox doping and stabilize the resulting charge carriers. A similar conclusion was reached by MacDiarmid *et al.*[22], who had homogeneously introduced sp^3-defect sites of the type —CHD— into polyacetylene and found that the $+(CH=CH)_nCHD+_x$ material has high conductivity with $\sigma \propto n^{3.2}$ dependence on the conjugation length for $n \geq 3$.

This work was supported by grants from the NSF and the Office of Naval Research. Magic-angle spinning ^{13}C-NMR data were obtained in collaboration with Drs P. Bernier and M. Audenaert of the CNRS at Montpellier, France.

Crustal structure south of the Iapetus suture beneath northern England

M. H. P. Bott, R. E. Long, A. S. P. Green*, A. H. J. Lewis, M. C. Sinha* & D. L. Stevenson

Department of Geological Sciences, University of Durham, Durham DH1 3LE, UK

The crustal structure just south of the Iapetus suture[1] along a line extending from the mid-North Sea high across northern England to the Solway Basin has been investigated as part of the Caledonian Suture Seismic Experiment of 1982. This unique sea-to-land wide-angle explosion seismology project has produced data of unprecedented quantity and quality. The main innovation was the use of both closely spaced shots (mainly at sea) and closely spaced stations (mainly on land), yielding a data set which can eventually be arranged in a variety of new ways for phase correlation and modelling, such as constant offset and common mid-point. The line was extended by Irish and German groups across Ireland to the Shannon Estuary, having a total length of over 600 km, but here we present only preliminary results for northern England and adjacent marine regions. The results for this region differ radically from those of the earlier LISPB experiment[2] in that we have recognized a well-defined 6.15 km s^{-1} basement interpreted as pre-Caledonian metamorphic basement beneath most of the line at relatively shallow depth, and there is a well-defined mid-crustal refractor starting at approximately 16 km depth beneath the North Sea and northern England which is not recognized beneath the Irish Sea.

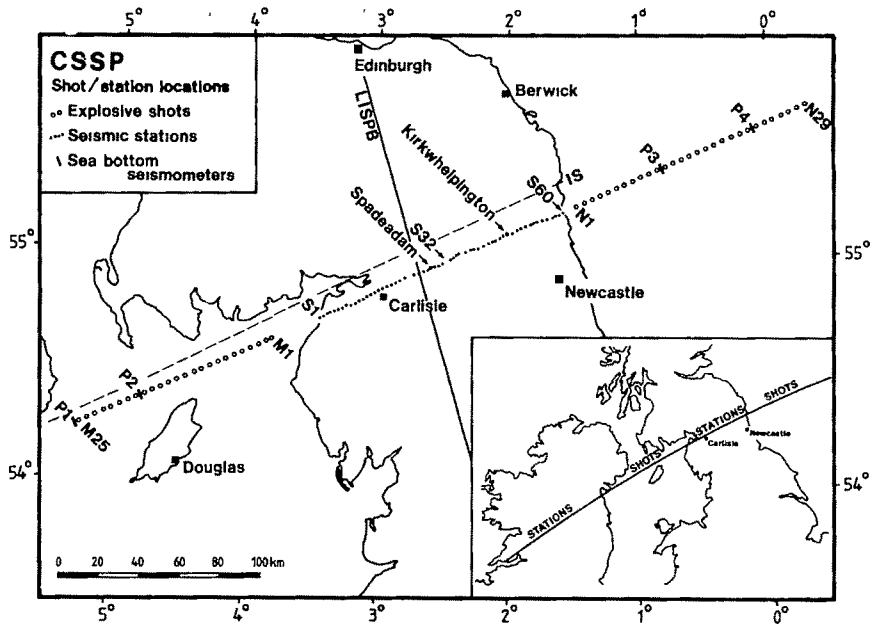

Fig. 1 Location of Caledonian Suture Seismic Project (CSSP), with details for Irish Sea to North Sea, showing also the supposed Iapetus suture[1] (IS) and the LISPB line[2].

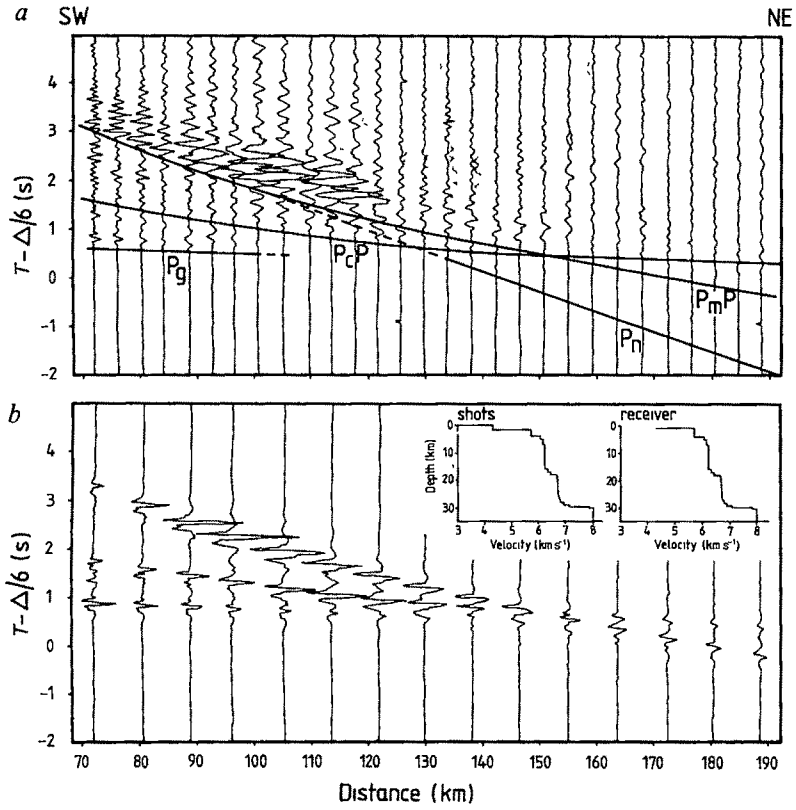

Fig. 2 *a*, Seismic recordings of North Sea shots N1–N29 at station S32 (Fig. 1) reduced to a velocity of 6.0 km s^{-1}, showing main phases computed for the synthetic model. *b*, Synthetic seismogram interpretation of *a* with inset velocity-depth distributions.

The following four main phases have been clearly recognized from the North Sea shots recorded in northern England, as illustrated by the recordings of the shots at station S32 (Figs 1, 2): (1) The first arrival beyond about 30 km is the P_g phase which has a velocity of 6.15 ± 0.02 m s^{-1} at 2–4 km depth as determined by time-term analysis. [The symbol P refers to compressional waves. P_g travels in the upper crust. P_cP and P_mP are wide-angle reflections or diving waves from respectively the mid-crustal discontinuity/gradient and the Moho. P_n is the Moho head wave refracted at the crust/mantle boundary.] P_g consistently dies out at all stations for shots beyond about N11–N13. Such decay of the P_g arrival has previously been cited as evidence for low-velocity zones in the upper crust. In the absence of laterally displaced sections containing similar offset distances, it has not been possible in past experiments to distinguish satisfactorily between the effects of a low-velocity zone and effects of lateral velocity variation in the upper crust. In this case, however, P_g is seen to decay in the vicinity of a specific shot position irrespective of station, so the cause must be interpreted as a lateral inhomogeneity near that shot position rather than as an underlying low-velocity zone. (2) A well-defined P_cP phase of apparent velocity ~6.5 km s^{-1} results from a steep increase in velocity with depth of ~6.22–6.5 km s^{-1} at 16–18 km depth, also detected in some earlier work[3,4]. (3) The P_mP phase representing the wide-angle reflection from the Moho is a clear large-amplitude arrival. (4) A small amplitude P_n phase of apparent velocity 7.9 km s^{-1} occurs as the first arrival beyond the crossover distance of 130 km. The P_mP and P_n phases are consistent with a sharp Moho at 30 km depth.

A model of the crustal structure assuming horizontal layering beneath the variable shallow structure, together with a synthetic seismogram computed using the reflectivity method[5], is shown in Fig. 2.

The Irish Sea shots recorded in northern England (Fig. 3)

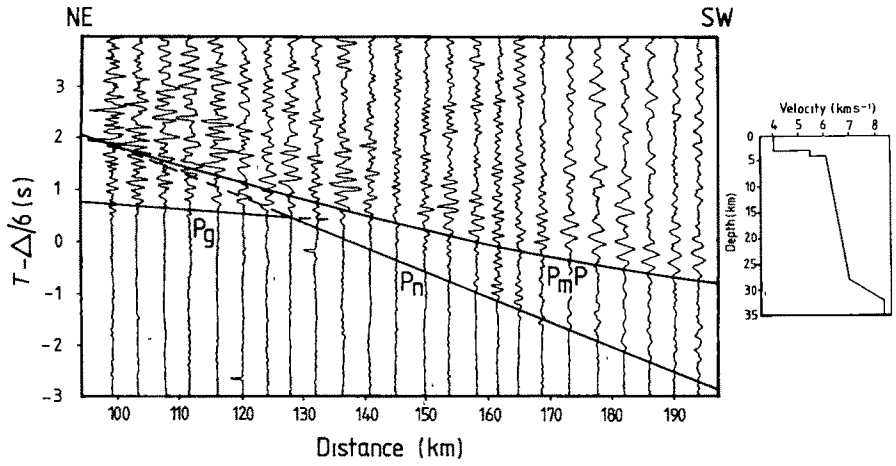

Fig. 3 Seismic recordings of Irish Sea shots M2–M25 at station S32 (Fig. 1) reduced to 6.0 km s^{-1}, showing the main phases computed by ray tracing for inset velocity–depth model.

yielded three main phases: (1) A P_g phase with a velocity of 6.15 ± 0.02 km s^{-1} determined by time-term analysis occurs as the first arrival between about 30 km and the crossover distance of 128 km, and comes from a depth of 2–4 km. Arrivals from shots over the Permo-Triassic basin beneath the Solway Firth are systematically delayed by the low-velocity sediments. (2) A conspicuous second arrival of 6.8–7.0 km s^{-1} apparent velocity is interpreted as the diving wave from a velocity gradient above the Moho at 28–32 km depth. (3) A P_n phase with an apparent velocity of 8.3 km s^{-1} or higher occurs as the first arrival beyond 128 km. The high apparent velocity is attributed to laterally varying time delays caused by the shallow sediment structure of the Solway basin.

A model of the velocity–depth distribution consistent with these three phases is shown in Fig. 3. A steep increase in velocity marking the top of a lower crustal layer, such as is indicated by the North Sea shots, is not apparent in the Irish Sea. Nevertheless, the possible existence of a higher-velocity lower crust, possibly underlying a velocity inversion at shallower levels, cannot be ruled out at this stage.

The shallow structure along the line of the experiment, which is probably just south of the Iapetus suture, is shown down to the 6.15 km s^{-1} basement in Fig. 4*a*. The structure down to the base of the Permo-Triassic was not resolved by the experiment and has been obtained from published sources[6] and from seismic reflection data supplied by Shell. The depth to the 5.5 km s^{-1} Lower Palaeozoic layer has been determined from first arrivals out to ~30 km range. The 6.15 km s^{-1} basement is well defined and its depth, as shown, has been inferred from time-term analysis.

The recognition of this 6.15 km s^{-1} upper crustal refractor at the relatively shallow depth of 4 km or less is a result of considerable significance. This layer extends down to about 16 km depth beneath the North Sea and Northumberland Trough, but its base is undetermined beneath the Irish Sea. The evidence indicates a slight increase in velocity with depth without obvious indication of a low-velocity layer within it. According to Hall *et al*[7,8], velocities >6.0 km s^{-1} at shallow depth beneath the Southern Uplands (north of the suture) represent crystalline metamorphic basement beneath the Lower Palaeozoic sequence rather than a metamorphic transition to greenschist facies within the Lower Palaeozoic[9]. Recordings along the Northumberland Trough of a land shot at Spadeadam (Fig. 1) indicate that the boundary between the 5.5–5.7 km s^{-1} Lower Palaeozoic rocks underlying the Carboniferous and the 6.15 km s^{-1} layer is sharp rather than gradational, which appears to rule out a metamorphic transition within the Lower Palaeozoic. The 6.15 km s^{-1} velocity is too low for oceanic crust. Both the velocity and the aeromagnetic anomalies[10] along the line are probably too uniform for island-arc-type crust. The simplest interpretation is that the Lower Palaeozoic rocks are relatively thin just south of the Iapetus suture, where they are underlain by crystalline basement which is probably formed of Precambrian metamorphic rocks. The contact could be an unconformity or a tectonic feature. This interpretation differs radically from the LISPB profile[2] crossing our line at Spadeadam, which indicated a 5.8–6.0 km s^{-1} Lower Palaeozoic basement extending down to at least 15 km depth.

A second important result is that the deep crust appears to differ between the North Sea/Northumberland Trough region

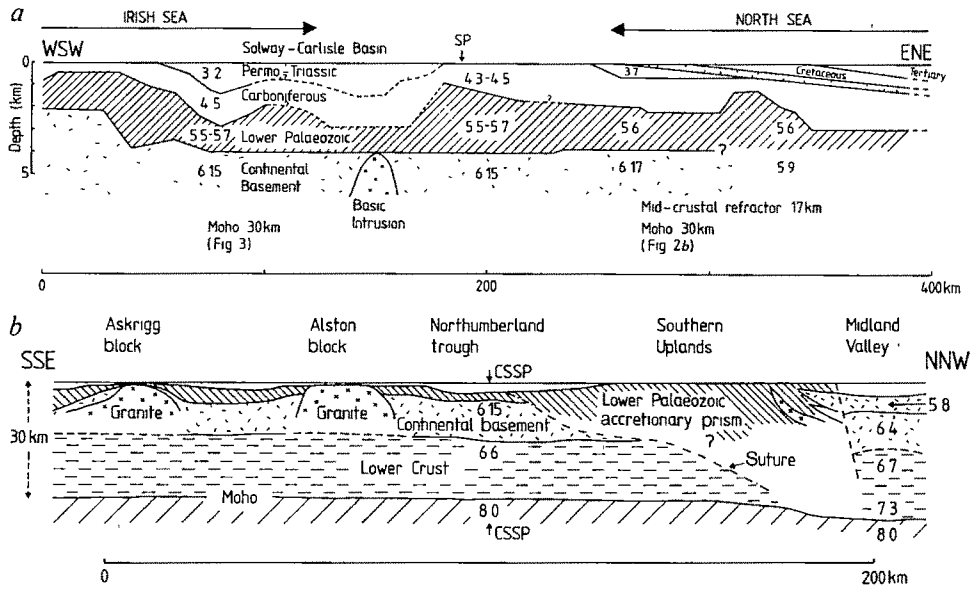

Fig. 4 *a*, Shallow crustal structure along the line of the experiment (Fig. 1), showing also the approximate locations of the crustal models of Figs 2*b* and 3. SP, Spadeadam. The basic intrusion beneath the Carlisle basin is inferred from the aeromagnetic map[10]. Seismic velocities in km s^{-1}. *b*, Speculative cross-section perpendicularly crossing the line of the experiment (marked CSSP) from the Midland Valley to the Northern Pennines, showing the possible relationship of the crust south of the Iapetus suture to the Southern Uplands accretionary prism. Seismic velocities are shown in km s^{-1} for this experiment (CSSP) and for the Midland Valley (LISPB[2])

and the Irish Sea region. P_cP has not been unambiguously detected beneath the Irish Sea, in contrast to the excellent North Sea development, and the Moho is interpreted as being gradational beneath the Irish Sea but relatively sharp beneath the North Sea. Taken at face value, this indicates juxtaposition of different crustal types along strike just south of the suture This conclusion, however, should be treated with some caution. The low-frequency P_cP and P_mP phases (Fig. 2) are most conspicuously developed for the shots in deeper water in the North Sea, which have significant energy in the 3-5-Hz band. It is possible that the lack of detection of P_cP for the Irish Sea shots, and the weaker P_mP development, may stem from the observed lack of significant energy in this band from the shallower Irish Sea shots. Future work aims to distinguish between these possibilities and to study transition between the two crustal types.

Comparison of our results with the relevant part of the WINCH crustal seismic reflection line[11] down the west of Britain is of interest. The WINCH line crosses the western extremity of our Irish Sea shot line, and a short section of WINCH was shot along the western end of our line to allow comparison between the vertical incidence and wide-angle surveys. A conspicuous feature of the WINCH data in the vicinity of our line is the concentration of strong sub-parallel and almost horizontal reflectors which occur at two-way travel times of 5-10 s, contrasting with the much more transparent regions above and below. The lower limit of these reflectors appears to correspond with the Moho, but from the present preliminary interpretation we have not been able to identify a velocity-depth signature beneath the Irish Sea corresponding to the upper boundary of the zone. It is possible that the distinctive 6.5 km s^{-1} lower crust at the North Sea end of our line corresponds to this zone of reflectors, which is well developed elsewhere on the mainland of England[12], but this needs future testing.

In conclusion, Fig. 4*b* is a speculative section showing our interpretation of how the crustal structure inferred from this experiment may relate to the Southern Uplands accretionary prism[13] to the north and the deep structure of the Pennine region[4] to the south The velocity-depth distribution beneath the Midland Valley comes from LISPB[2] and the Iapetus suture itself has been inserted in the form suggested by the WINCH line[11] further west. The relationship of the Lower Palaeozoic accretionary prism to the overthrust southern crust explains the observation of a 6.5 km s^{-1} lower crust beneath Eskdalemuir in the Southern Uplands[3] and why a higher velocity lower crust was not detected by LISPB[2].

We thank NERC, the Royal Society, the University of Durham, Mobil and Esso for research grants, Shell for a Studentship (A H.J L) and NERC for shiptime and loan of seismological field equipment We also thank those who gave field assistance during the project.

Hydrothermal manganese plumes in the Mid-Atlantic Ridge rift valley

G. Klinkhammer*, P. Rona†, M. Greaves* & H. Elderfield*

The concentration of dissolved manganese in sea water can be used as a chemical tracer of hydrothermal activity on the underlying sea floor. Here we present vertical profiles of seawater manganese concentrations above the rift valley of the Mid-Atlantic Ridge (MAR). The values obtained indicate the presence of plumes that are presently active generated by hydrothermal vents in the rift valley. These plumes are confined to the rift valley and do not spill over into the adjacent deep ocean basins. Differences between them suggest that there are at least five hydrothermal sources along this 1,700-km-long section of mid-ocean ridge.

The 9 MAR sites (Fig. 1) were preselected on the basis of various indicators of either former or present hydrothermal activity including a magnetic signature characteristic of hydrothermal alteration of the basaltic layer of oceanic crust[1], excess ^3He in the water column and hydrothermal mineralization on the sea floor[2,3]. Manganese has been established as a sensitive tracer of hydrothermal emanations[4-8].

The analyses were carried out as part of an extensive regional survey by the NOAA ship *Researcher* of the MAR between the TAG site at 26°N and the Vema Fracture Zone at 11°N in August 1984. Manganese was measured on board ship by flameless atomic absorption after preconcentration with oxine[9] to give a detection limit of 0 05 nmol kg^{-1}, four times lower than manganese concentrations normally found in deep-ocean waters[10]. A portable Zeeman tungsten furnace atomic absorption spectrophotometer (model AAZ, Scintrex Corporation) was used.

Most manganese data for ocean waters have been reported as 'total dissolvable manganese' (TDM), that is, the amount of manganese measured in an unfiltered sample after acidification to *p*H 2 with hydrochloric acid[11]. TDM represents essentially all the manganese, both dissolved and particulate, except for possibly the most refractory component[9]. Selected samples were analysed for TDM. However, TDM analyses are unsuitable for survey work because samples must be stored at *p*H 2 to ensure that leaching of particles is complete. To overcome this problem, samples were analysed without prior acidification In this way, six samples could be analysed within <2 h after the samples had arrived on deck. The manganese measured before acidification will be referred to as 'total reactive manganese' or TRM.

Samples were collected in 5-l Niskin and 30-l Go-Flo bottles mounted on a rosette or strung on a hydrowire. Fourteen aliquots including eight from plumes in the rift valley were filtered before being analysed for manganese. The average coefficient of variation between the concentrations of these filtered aliquots and the corresponding TRM results was 3.8%. This exercise demonstrates that TRM represents mainly the dissolved fraction as defined by passing through 0.4-μm filters. The difference between TDM and TRM is the manganese released from particles by acidification to *p*H 2 or acid-soluble manganese (ASM). In deep Atlantic waters not affected by hydrothermal discharge, excess particulate manganese is <0.04 nmol kg^{-1} (ref. 12), below the detection limit of the method used here. Therefore, in deep waters not affected by hydrothermal activity or resuspension, TDM and TRM should be equivalent within our analytical precision, which they were at the control station (Fig. 2*a*).

Typically, a manganese-depth profile of the open ocean is similar to the one at Vents station 1 (Fig. 2*a*) over abyssal hills some 660 km west of the MAR (26°00.0′ N; 51°00.0′ W). This profile, a control with which to compare results from the rift valley, consists of a surface water maximum of 1.63 nmol kg^{-1} and deep-water values of 0 26 ± 0.08 nmol kg^{-1}; these results are

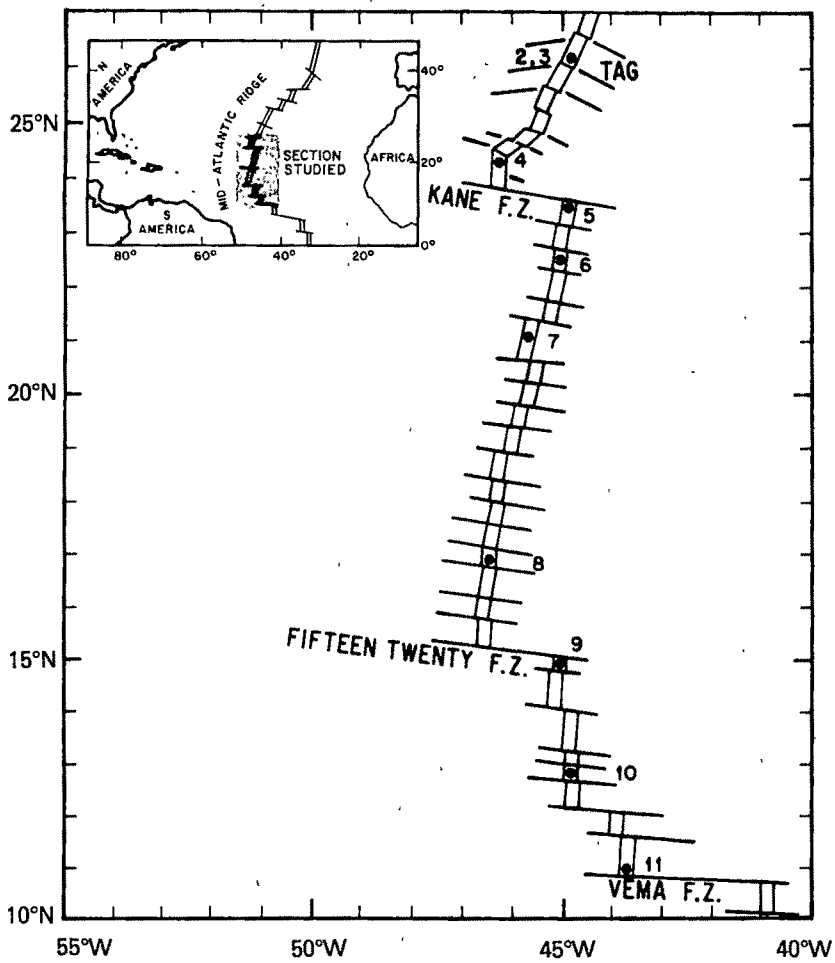

Fig. 1 Study area. Water sampling during the survey consisted of 11 stations: station 1, the control station west of the spreading centre, and stations 2–11 in the median valley of the MAR.

similar to data published for the nearby Nares Abyssal Plain[13]. Input from aeolian and riverine sources result in surface-water maxima at northern latitudes, but oxidation and scavenging maintain much lower concentrations in deep waters. Three processes may produce manganese anomalies below 1,000 m at open ocean sites: (1) diffusion from sediment after diagenetic remobilization; (2) resuspension of sediment by bottom currents; or (3) discharge of hydrothermal effluents. Diffusion from sediments is unlikely to be significant at our sites for two reasons. First, most deep-sea sediments are capped by an oxidizing layer that traps remobilized manganese within the sediment[14]. Second, there is very little sediment accumulation in the rift valley. Process (2) may produce an anomaly near the bottom, but such a signal is associated with particulate matter and thus would result in an anomaly in TDM but not TRM. In conclusion, the manganese anomalies discovered during this survey are most certainly produced by process (3).

Manganese is highly enriched in hydrothermal effluents because it is leached from basalt during hydrothermal circulation. The concentration of manganese in a hydrothermal end-member is ~1 mmol kg^{-1} (refs 15, 16), five million times greater than in deep ocean waters. Figure 2*b* is a TDM-depth profile over the vent field at Galapagos[4]. The buoyant hot-spring effluents emanating from the Galapagos Spreading Centre create a manganese anomaly that extends from the sea bed some 1,000 m into the water column. In contrast, the profile above the 'black smokers' at 21°N contains a manganese maximum 220 m above the sea floor (Fig. 2*c*)[6].

As well as the size and shape of the anomaly, the partitioning of manganese between dissolved and particulate phases provides useful information. Determining partitioning is useful because the manganese in reducing hydrothermal fluids is dissolved, but once discharged into oxygenated sea water, it converts to the particulate form as a result of oxidation and scavenging. Hence, the proportion of manganese present as particles is an indication of the age of the hydrothermal signal. Here, the difference between TDM and TRM (that is, ASM) will be used to infer distance from a source. However, we note that ASM is a function of time and not distance and, because both the kinetics of ASM formation and the directions of currents at our sites are unknown, such deductions should be considered tentative. Our results are presented in Table 1 and Fig. 3*a*–*i*.

Stations 2, 3 (TAG; Fig. 3*a*): Previous evidence for hydrothermal activity at the TAG site was substantial. The area is characterized by rapidly accumulating manganese crusts[17] and high metal contents in sediments[18]; temperature[19] and helium[20] anomalies in bottom waters have also been reported.

The manganese results from the TAG site show that there are active hydrothermal vents on the MAR, a conclusion supported by results from other sites occupied during the survey. Whether or not there are active vents at the TAG site is less clear. The manganese anomalies at station 2 are consistent with the presence of hydrothermal emanations from the east wall, as concluded from previous work at TAG[21]. If the anomaly is maintained by local activity, the largest sources probably occur at 3,450 m, somewhat deeper than previously thought. However, the results from TAG do not eliminate the possibility that the manganese anomaly here is advected from elsewhere along the MAR and that there is no present-day venting at this site. Indeed, the observation of large amounts of particulate manganese at station 2, L2, would support such a conclusion.

Station 4 (Fig. 3*b*): It is irrefutable that the excess manganese at this site is the result of hydrothermal activity. The shape of this profile is reminiscent of those found in the South Pacific[8] and could result from buoyant emanations from the valley floor, advection from the valley wall(s) near these locations or advection from vents some distance away. The small concentrations encountered and the observation that >20% of the anomalous TDM is associated with suspended particulates suggests that the anomaly here is an advected feature.

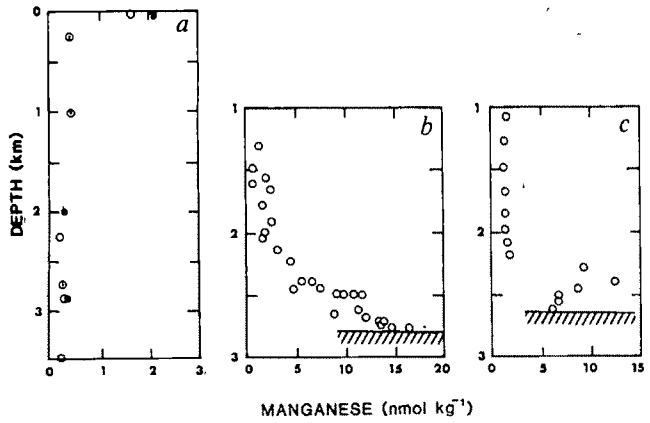

Fig. 2 *a*, Manganese-depth profile at the control station. Solid circles are total reactive manganese (TRM) and open circles are total dissolvable manganese (TDM). Circles with dots indicate identical concentrations within precision The bottom depth is ~5,000 m. *b*, TDM profile over the hot springs on the Galapagos Spreading Centre (redrawn from ref. 4). *c*, TDM profile over the 'smokers' on the East Pacific Rise at 21° N (redrawn from ref 6). The hatched lines in *b* and *c* indicate the bottom depth.

Station 5 (Fig. 3*c*): This station is in the rift valley at its eastern intersection with the Kane Fracture Zone (Fig. 1). Again, evidence for present-day hydrothermal activity was found. Whereas the size, shape and position of the anomaly here are similar to those at station 4, the form of the manganese is distinctly different; that is, there is very little particulate manganese (ASM) at this station, suggesting closer proximity to a source.

Station 6 (Fig. 3*d*): There is a distinct manganese anomaly at this station and very little ASM, indicating close proximity to active vents. The deepest sample has more particulate manganese, which may be explained by resuspension of sediments. The most obvious difference between the profile at station 6 and those further north is that the maximum concentration occurs much shallower, at 3,000 m as opposed to 3,500 m (although there is a small anomaly at 3,500 m as well).

Station 7 (Fig. 3*e*): The TRM anomaly at this location is the smallest found in the rift valley. There is 0.2–0.3 nmol kg^{-1} of particulate manganese in most samples as well, which may be related to the fact that the axis of the rift valley is anomalously offset ~30 km to the west at this site.

Station 8 (Fig. 3*f*): The TRM profile at station 8, L2, was obtained by positioning the rosette over the east wall at a depth as near as possible to 3,800 m. The most probable explanation for these results is that the rift valley anomaly (station 8, L1) is produced by advection of hydrothermal manganese from hot springs on the east wall at this site and that this venting occurs at a depth of 3,800 m. This tentative conclusion is based on four observations: (1) the maximum TRM concentration in the valley is 1.90 nmol kg^{-1}, compared with 2.58 nmol kg^{-1} over the wall; (2) these maxima occur at approximately the same depth in both profiles; (3) there is much more ASM in the valley, indicating that the signal there is older; (4) the shape of the east wall profile is similar to the one obtained over hot springs on the Galapagos Spreading Centre (Fig. 2*b*).

Station 9 (Fig. 3*g*): The results from station 8 suggested that the venting there may be asymmetrical about the spreading axis, that is, occurring on the east wall but not the west wall. To examine this problem more closely, two rosette lowerings were made at station 9. These results demonstrate that the distribution of hydrothermal manganese is asymmetrical at this site. Because the manganese plumes contain large quantities of ASM, both locations at this site may be somewhat removed from the nearest vents. The ASM results are similar to the concentrations of 'excess' manganese (0.6–1.0 nmol kg^{-1}) found by Lambert *et al.*[12] in the rift valley at 14°15′ N. The shapes and relative sizes of the anomalies suggest that the nearest venting is associated with the east wall and that the anomaly on the west wall is produced by westward advection.

Station 10 (Fig. 3*h*): The maximum in the valley occurs at about 3,600 m and is larger than the maximum over the east wall. These observations, together with the presence of more suspended particulate manganese at the east wall location, makes westward advection similar to that deduced for station 9 improbable. Indeed, the results are more compatible with a west wall source at this site.

Station 11 (Fig. 3*i*): This station was positioned in the rift valley at its western intersection with the Vema Fracture Zone. The TDM results demonstrate that the anomaly over the east wall is essentially all dissolved manganese. Given this evidence, station 11 must be considered as a promising site for more detailed investigation.

We conclude from the manganese plumes discovered during this survey that there are active hydrothermal vents along this section of the Mid-Atlantic Ridge. The differences between these plumes make it virtually impossible for them to have originated at the same vent field. First, they occur at different depths (2,900–3,800 m), over different ridge segments (Fig. 1) offset by as much as 150 km. Furthermore, the size and shape of the anomaly change, both across the rift and along the spreading

axis. Finally, the proportion of the excess manganese associated with particles is variable.

By taking a conservative approach and grouping those plumes in which the maxima occur at the same depth, five sources can be identified, that is stations 2, 4 and 5; stations 6 and 7; station 8; station 9; and stations 10 and 11. This analysis predicts a frequency of one source per 340 km of ridge; of course the actual frequency may be much higher.

The position of venting in the rift appears to vary with latitude. Results from stations 8 and 9 are consistent with venting from the east wall, whereas results from station 10 indicate a west-wall source Furthermore, these results are consistent with discharge from the valley walls, but they do not eliminate the possibility that venting occurs from the valley floor. Finally, hydrothermal manganese along this section appears to be confined to the median valley and does not spill over into the adjacent ocean basins, although it may leak out through fracture zones.

The anomalies reported here are smaller than those found near venting in the Pacific[4-7]. However, this difference is an artefact of the regional sampling strategy of this survey and is not a true indication of the relative impact of venting from the MAR on geochemical cycles and the heat budget. Such information can be acquired only by site-specific work.

We thank Captain R. L. Swanson, officers and crew of the NOAA ship *Researcher* for their support and T. A. Nelsen of NOAA and J. Trefry of Florida Institute of Technology for their cooperation. This work was supported by the NOAA Vents programme and the NERC; Cambridge University Earth Sciences Series, contribution 578.

Fractal dimension of vegetation and the distribution of arthropod body lengths

D. R. Morse*, J. H. Lawton*, M. M. Dodson† & M. H. Williamson*

Departments of *Biology and †Mathematics, University of York, York YO1 5DD, UK

Following Mandelbrot[1], recent studies[2-6] demonstrate that some natural surfaces are fractal. Here we show that transects across vegetation are fractal, and consider one possible consequence of this observation for arthropods (mainly insects) living on plant surfaces. An important feature of a fractal curve or surface is that its length or area, respectively, becomes disproportionately large as the unit of measurement is decreased[1]. This suggests that if vegetation has a fractal structure, there is more usable space for smaller animals living on vegetation than for larger animals. Hence, there should be more individuals with a small body length than a large body length. We show that this is the case, and that relative numbers of small and large individual arthropods collected from vegetation are broadly consistent with theoretical predictions originating from the fractal nature of vegetation[7] and individual rates of resource utilization.

Mandelbrot[1,4] asks, how long is the coast of Britain? Measuring its length by stepping round with successively shorter divider step-lengths allows finer and finer resolution of the coastline; if the log of divider step-length is plotted against the log of total length measured, a straight line of negative slope is obtained[1,4,8]. Mandelbrot[1,4] interprets this as evidence that coastlines are fractal and that the slope of the graph is an estimate of $1-D$, where D is the fractal dimension of the coastline. The relationship between D, step-length r and the perceived length of the line $l(r)$ measured with step r is given by

$$l(r) \propto r^{(1-D)} \quad (1)$$

By definition[1], for a line (that is, a transect across a surface), D must lie in the range $1 \leq D \leq 2$ and for a surface, $2 \leq D \leq 3$.

The fractal dimension of vegetation might also be measured by stepping along a transect over the surface with a pair of dividers set to a series of step-lengths and using equation (1). This was the method used to measure the fractal dimension of transects across a coral reef[6]. An alternative widely used method (see ref 1, p. 130), which has some practical advantages, is as follows.

Enclose the object (or a subsection of it) in a square of side S and divide the square into $(S/\lambda)^2$ squares of side λ. Let $N(\lambda)$ be the number of squares the edge of the object enters and plot $\log N(\lambda)$ against $\log 1/\lambda$. Suppose that for small values of λ, the graph is almost linear with slope D. Then D can be interpreted as the fractal dimension, since

$$\log N(\lambda) \approx D \log 1/\lambda + \log K \quad (2)$$

where K is a constant, whence

$$N(\lambda)\lambda^D \approx K \quad (3)$$

The method is explained in greater detail in Fig. 1 legend, together with an example.

Photographs were taken of a variety of plants during early spring. The plants were either leafless, just coming into leaf or evergreen. By careful choice of plant-parts and camera focal length, the resulting photographs were approximately two-dimensional, greatly simplifying their interpretation under the grid (Fig. 1*a*). Two different arbitrarily sized grids (128 mm or 256 mm along one edge) were partitioned into 2^n squares along each edge. Depending on the grid size, n varied from 2 to 6 or 7, down to a square size of 2 mm. The grid was randomly repositioned several times to give semi-independent estimates of the fractal dimension of the same piece of vegetation. The slope of the resulting line (for example, Fig. 1*b*) was estimated by regression analysis.

There are several points to note in the interpretation of such graphs. One is that when the number of divisions is small, it is probable that all the squares will be entered, hence the slope of the graph will be $D=2$. This is an artefact of the method; consequently, in the present study all points that fell on the line $y=2x$ (on a log/log plot) were omitted when estimating the slope of the line. At the other extreme of resolution, when a very large number of squares is used, the slope of the graph will in general fall to 1. This could be due to a lack of resolution in the photograph or because irregularities in the outline of the plant no longer occur at that scale. Taking a photograph at a much larger scale (higher magnification) resolves this problem. The graph may be convex[9,10] between the extremes of $D=2$ and $D=1$, or it could have two straight subregions characterized by different slopes (Fig. 1*b*). Similar changes in fractal

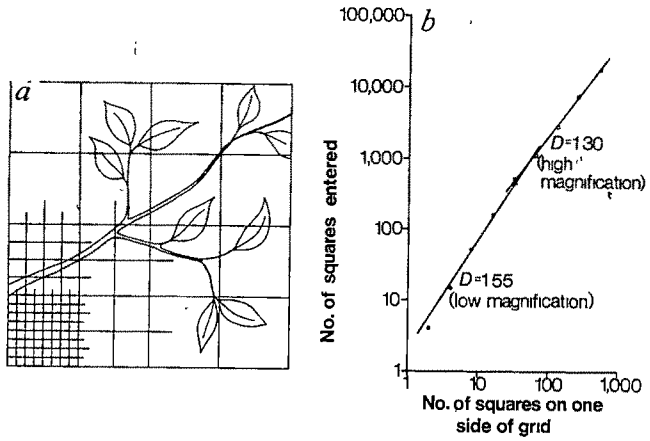

Fig. 1 *a*, Photographs of plants at various magnifications were placed under a grid. The number of squares entered by the outline of the plant were counted, starting with a course grid of two large squares on one side, then 2^n squares, with n varying from 2 to 6 or 7, depending on the grid size. For ease of representation, the plant's leaves in this figure are drawn flat; in reality they are orientated at all angles with respect to the grid. Also for clarity, the progressively finer divisions are only illustrated in one corner of the figure. The logarithm of the number of squares entered by the outline of the plant was then plotted against the logarithm of the number of squares along one side of the grid, as in *b*. The slope of the line equals the fractal dimension, *D*. *b*, Data gathered in this way for Virginia creeper, photographed without leaves in early spring. The twigs were photographed at one scale, then parts of the same twigs were rephotographed at a higher magnification, permitting *D* to be estimated at two levels of resolution.

dimension at different scales have been found in other natural objects[1,3,11].

Table 1 presents data on the fractal dimension of a selection of plants. Estimates of *D* range from 1.28, for a close-up photograph of Virginia creeper, to 1.79 for cotoneaster. Those plants which one might, *a priori*, consider to have a more complex growth form have a higher fractal dimension. In those plants which were photographed at two scales, estimates of the fractal dimension are lower at the higher magnification, as would be expected from the above argument.

The mean fractal dimension of the samples in Table 1 is 1.44. For ease of calculation, assume that, typically, $D \approx 1.5$. It follows from equation (1) that for an order-of-magnitude decrease in ruler length, the expected distance between two points on a linear transect (of dimension $D = 1.5$) across a fractal surface increases by a factor of $\sqrt{10} = 3.16$. The difficulties of measuring the fractal dimension of a surface are considerable and no data are yet available. However, squaring the increase in linear distance (that is, adding the fractal dimensions of the orthogonal transects; ref. 1, p. 365) gives a heuristic upper bound estimate for the expected increase in surface area. Therefore, the maximum expected increase in surface area is $3.16^2 = 10.0$ for an order-of-magnitude decrease in ruler length. Bearing in mind the disconnected character of the surface of vegetation, an estimate for the lower bound of the fractal dimension is obtained by adding 1 to the linear fractal dimension (for example, 1.5 + 1; see ref. 1, p. 365). This holds exactly under some circumstances, and in particular when the surface is flat in a direction transverse to the cross-section (which is clearly not the case for vegetation). This lower bound predicts a 3.16-fold increase in surface area for an order-of-magnitude decrease in ruler length, when $D = 1.5$.

Now consider the implications of the fractal nature of plant surfaces for the animals living on them. As a first approximation, substitute animal body length (L) for step-length (λ) in equation (1). If the way in which animals perceive and use their environment is proportional to their body length[12], then for a homogeneous fractal surface having transects with $D = 1.5$, the area perceived by animals 3 mm long may be up to an order of magnitude greater than the area perceived by animals 30 mm long, for the same reference area. This increase in available space for animals of smaller body length may be combined with a consideration of the way in which metabolic rate scales with body length[13,14] to make predictions about the distribution of body lengths of animals living on vegetation.

The metabolic rate of individual animals[13,14] scales approximately as the 0.75 power of body weight, W, that is, as $(L^3)^{0.75}$. Next, suppose that population densities are approximately proportional to the reciprocal of individual rates of resource utilization (that is, to metabolic rate^{-1}; see, for example, ref. 13). Then, if use of resources per individual is proportional to $W^{0.75}$, it follows that population density, N, scales as $(L^3)^{-0.75}$. Hence, all other things being equal (especially the rate of appearance of new resources), a 10-fold decrease in body length results in a $(10^3)^{0.75} = 178$-fold increase in the density of individuals. This increase in density may be combined with the expected increase in the available surface area, outlined above, for a given decrease in body length, to predict relative numbers of individual animals of different body lengths living on the surface of vegetation. For an order-of-magnitude decrease in body length, such calcula-

Ash, *Fraxinus excelsior* L. (twigs and leaves)	Medium	3	1.42	0.083
Sycamore, *Acer pseudoplatanus* L. (twigs and leaves)	Medium	3	1.31	0.023

Photographs of branches and twigs of a selection of woody plants, with or without leaves, were taken from the University of York campus or Skipwith Common, North Yorkshire. High-magnification estimates were derived from close-up photographs of twigs ~10 cm long; low-magnification estimates were from photographs of twigs >50 cm long. Single medium estimates were made from specimens >25 cm long. The state of each plant when photographed and the plant part photographed is indicated in parentheses after the species name. (Note that sample transects inevitably tended to follow twigs and other 'principal axes' in the natural structure of the vegetation. This could introduce some bias into the estimates of their fractal dimension.)

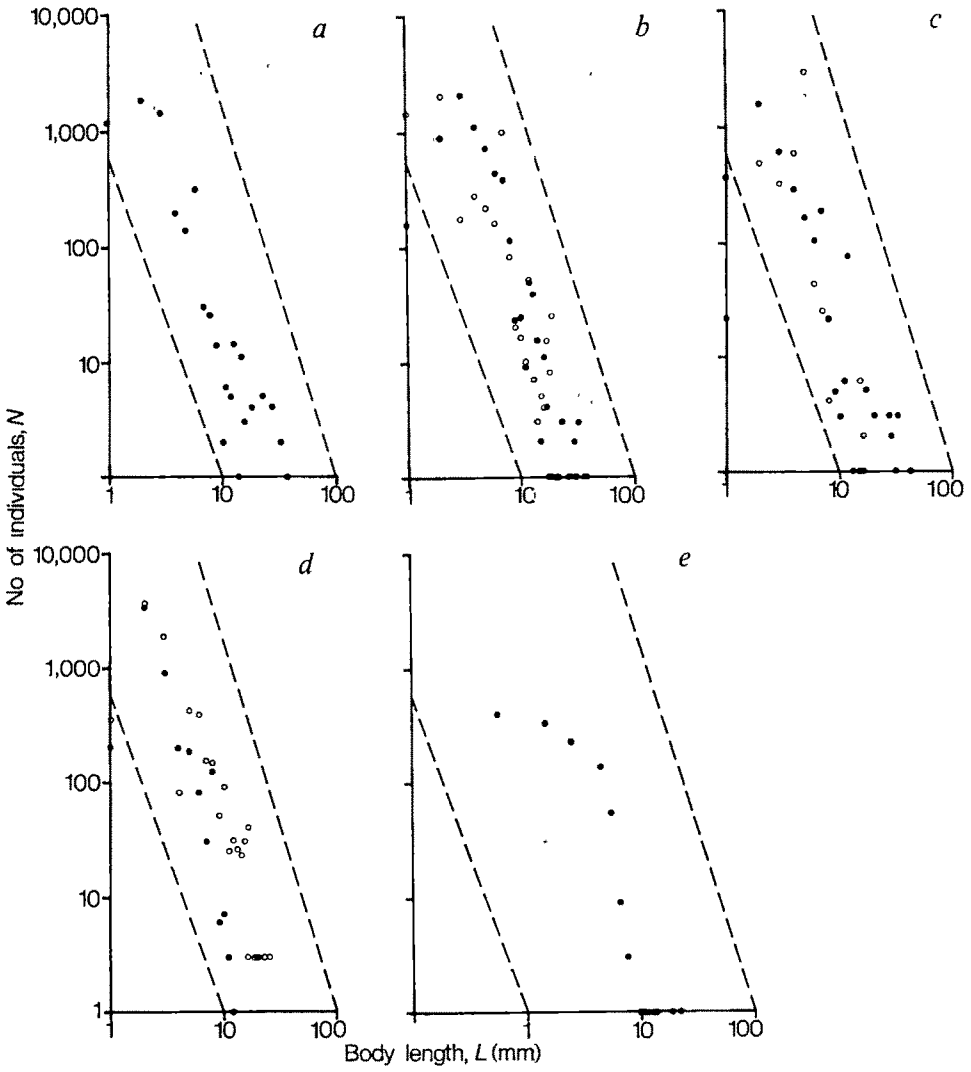

Fig. 2 Data on the number of individual arthropods (mainly insects) of different body lengths collected from vegetation. *a*, Understorey foliage in primary forest, Finca Tabogo, Costa Rica[15]; *b*, Osa secondary vegetation (●) and Kansas secondary vegetation (○); *c*, Tabogo primary riparian vegetation (●) and Icacos vegetation (○)[16]; *d*, understorey foliage in cacao plantations in Dominica (●) and at Finca La Lola, Costa Rica (○)[17]; *e*, Birch (*Betula pubescens*) trees at Skipwith Common, North Yorkshire. In *a*–*d*, arthropods were collected by sweep net, in *e* by pyrethrum knock-down of the tree canopy. The lower bound prediction that, for an order-of-magnitude decrease in body length, there should be a 560-fold increase in the number of individuals, is indicated by the lower dashed line on each graph; the upper bound prediction—a 1,780-fold increase for an order-of-magnitude decrease in body length—is shown by the upper dashed line. Regression lines were fitted through the log-transformed data, the anti-logarithm of the slopes of the lines were taken and are as follows: *a*, 390; *b*, 1,040 (●) and 700 (○); *c*, 360 (●) and 980 (○); *d*, 21,800 (●) and 530 (○); *e*, 1,440. The decline in the numbers of individuals of <1 mm body length may be due to a variety of factors[12], not least of which is the difficulty in sampling very small arthropods Consequently, when fitting regression lines to the data, in *a*–*d* the 1 mm body length data point and in *e* the first three data points were omitted.

tions predict an increase of between $178 \times 3.16 = 560$-fold and $178 \times 10 = 1{,}780$-fold in the number of individual animals[7].

Data on the number of individual animals of different body lengths collected from the surface of vegetation are scarce. Figure 2 shows such data for sweep-net samples of terrestrial arthropods[15–17] and original data collected by pyrethrum knock-down of a tree (*Betula pubescens*) canopy. All the data show a steep increase in the number of individuals for an order-of-magnitude decrease in body length, in general agreement with our predictions (Fig. 2).

The above heuristic calculations may be reversed, allowing prediction of the expected fractal dimension of the surface of vegetation, given the mean of the fitted slopes for the distribution of individuals' body lengths shown in Fig. 2. This calculation results in a prediction of the fractal dimension of the surface of vegetation of $D = 2.78$.

Clearly, approximate agreement between data and our predictions does not prove that the fractal nature of vegetation contributes to a steep increase in number of individuals as arthropods get smaller. Moreover, different values for D (1.28–1.79; Table 1) and the metabolic rate exponent (0.62–0.86; refs 13,14) lead to different predicted slopes in Fig. 2, as will the precise form of the relationship between the fractal dimension of a surface and transects across that surface. It remains to be seen whether detailed differences in the fitted slopes apparent in Fig. 2 can be explained by differences in the fractal dimension of particular plant surfaces, and by the biology of associated arthropods.

We know of no other attempts to explain patterns in the body size distributions of arthropods living on plant surfaces, although previous studies have examined species/frequency distributions for animals of different sizes[12,18]. Theoretical and empirical links between patterns in the number of species and number of individuals of different body lengths constitute an important unsolved problem.

Education policy and the heritability of educational attainment

Many workers assume that genetically determined differences in intellectual ability[1–5] will be influenced little by changes in educational policy or other environmental interventions[6,7]. Others[8,9], however, have suggested that increasing equality of educational opportunity will lead to an increase in the heritability of educational attainment. The resolution of this issue has been delayed until now because of the extremely large sample sizes which would be required[10]. Education data on twins and their parents, from the Norwegian twin panel[11,12], provide a unique opportunity to determine the impact on the heritability of educational attainment of the more liberal social and educational policies introduced in Norway after the Second World War[13]. As reported here, for individuals born before 1940 there is a strong effect of family background on educational attainment, accounting for 47% of the variance, though genetic factors account for an additional 41% of the variance. For females born after 1940 and before 1961, the relative importance of genetic (38–45%) and familial environmental (41–50%) differences changes very little. For males born during the same period, the broad heritability of educational attainment has increased substantially (67–74%), and the environmental impact of family background has correspondingly decreased (8–10%). For males, at least, having well-educated parents no longer predicts educational success, as measured by duration of education, independent of the individual's own innate abilities.

Adult twins from the Norwegian twin panel, a population-based register of like-sexed twins born in Norway between 1915 and 1961 and presently resident there, were asked, by mailed questionnaire, to report the duration of their own education (I, 0–7 yr; II, 8–9 yr; III, 10–12 yr; IV, over 12 years of education) and that of both their parents. Questionnaires were returned by one or both twins from 8,389 families. Each member of 4,608 twin pairs reported his own educational level. Although well-educated twin pairs were overrepresented in the sample of respondents, the sample obtained was more nearly representative of the adult population than the samples obtained in most volunteer studies[11]. Polychoric correlations[14] for educational attainment were computed between male and female monozygotic (MZ) and dizygotic (DZ) twin pairs, between the parents of twins, and between parent and offspring for twins born before 1940, during 1940–49 and during or after 1950 (Table 1). (We report correlations rather than variances and covariances[15], as we are not making any predictions about the effects of social policy on the variance in educational attainment.) Data from all the twins were used in computing the two-way contingency tables from which polychoric correlations between parent and offspring were calculated. Data for each member of a twin pair were treated as independent observations in computing the parent/offspring contingency tables. Data from only the first twin to report were used to compute the parent/parent contingency tables.

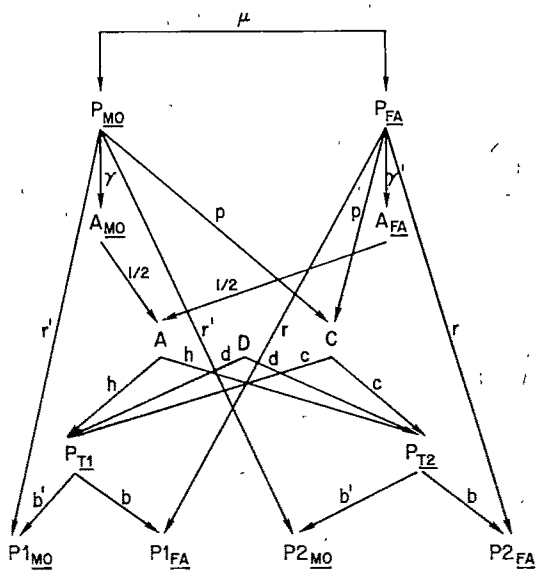

Fig. 1 Path diagram for MZ twins and their parents

We found that correlations between male and female MZ twins have changed little over the time period studied, implying that the total contribution of familial factors (both genetic and environmental) to variation in educational attainment has remained constant. The change in the correlation between parents (0.85 to 0.79), though statistically significant because of the very large sample sizes, is also very small. There is a slight decline in the correlation between female DZ twins for twins born after 1940 (0.75 to 0.68), but a much more pronounced decline for male DZ twins (0.77 to 0.48); such a decline, relative to the MZ correlation, would be predicted if the influence of genetic differences on educational attainment has become more important in twins born after 1939. A corresponding decline in the parent/offspring correlations also occurs, the change in the parent/son correlations being greater than the change in the parent/daughter correlations.

Combining self-report data from the twins with the education data which they report for their parents allows us to overcome many of the limitations of the classical twin design[15–17]. Provided that the effects of dominance or genotype × age interaction are not too great, this design will resolve the contributions to variation in educational attainment of additive gene action, the environmental effects of parental education, other environmental effects shared by twins or siblings which are unrelated to parental education, and the genetic consequences of assortative mating. We shall not, however, be able to resolve alternative

Polychoric correlations are given in the lower triangle of each matrix, their standard errors in the upper triangle (1) First twin's education, (2) second twin's education, (3) mother's education (first twin's report), (4) mother's education (second twin's report), (5) father's education (first twin's report), (6) father's education (second twin's report) -, No estimate of standard error possible due to very low expected cell frequencies

hypotheses about mechanisms of mate selection and environmental transmission within families[18]. As we have separate reports of parental educational levels by each member of a twin pair, we can check the validity of such data.

Table 2 shows matrices of polychoric correlations, broken down by twin group and birth-cohort, between the educational levels of each twin, and the educational level reported by each twin for each parent; only twin pairs where each twin reported the educational levels of himself and both parents were used in computing these correlations. For some of the polychoric correlations in Table 2 no standard errors are given, because of very low expected frequencies for one or more cells of the two-way 4×4 tables from which the polychoric correlations are derived. Such coefficients may be strongly biased estimates of the true population correlations[14] and so were not used in any data analyses Agreement between twins is very good, correlations between educational levels reported by each twin for the same parent ranging from 0.86 to 0.98. However, the correlation between a twin's educational level and that which he reports for either parent is consistently higher than the correlation between his own educational level and the educational level reported by his co-twin for the same parent. Fortunately, we can allow for the effects of this bias, by model-fitting.

Figure 1 presents a path model[12,19] for deriving expected correlations between the educational attainments of MZ twins and the educational attainments reported by them for their parents P denotes true educational attainment (we assume that the twins make no error in reporting their own educational level), and P1 and P2 the educational attainments reported by first and second twins, respectively, for mother (subscript MO) or father (subscript FA). The standardized path regressions of true phenotypic value on additive genetic deviation (A), dominance deviation (D), familial environmental deviation (C) and random environmental deviation (E. omitted from the diagram to simplify presentation) are denoted by parameters h, d, c and e, or for females, in models which allow for sex-dependent effects, h', d', c' and e'. The path regression of additive genetic deviation on true phenotypic value is denoted by the parameter γ' in males, or γ in females, where $\gamma' = h + ac$, $\gamma = h' + ac'$, and a is the genotype/environmental correlation which may be expressed as a function of the other parameters of the model[3]. The path regressions of reported parental educational attainment on true parental educational attainment and on the twin's educational attainment are denoted by b and r for fathers, b' and r' for mothers Path regressions of offspring familial environmental value on true maternal or paternal educational attainment are denoted by the environmental transmission parameter p. The parameter μ denotes the correlation between the educational attainments of spouses, which is assumed to arise through phenotypic assortative mating[20]. An equivalent diagram can be drawn for DZ twins, and expected correlations derived

Models were fitted to the polychoric correlations in Table 2 by nonlinear weighted least-squares, using the standard errors of the polychoric correlations as weights, and treating the correlations as though they were independent. Strictly, these correlations are not independent. However, ignoring the correlation between correlations has been found to have little effect on the parameter estimates obtained[21]. Model-fitting yields estimates of model parameters and provides an approximate χ^2 value with which to assess the fit of a given model, and compare its fit with that of other models. The validity of the χ^2 statistic will depend on how closely the sampling distribution of the polychoric correlation coefficients approximates to the multivariate normal distribution With these very large sample sizes we expect the approximation to be close.

For twins born before 1940, there is no evidence for sex differences in the familial transmission of educational attainment A purely environmental model gives a good fit to the data ($\chi^2_{44} = 42\,18$, $P = 0.55$), although allowing for additive genetic variance gives a significant improvement in fit ($\chi^2_1 = 7.81$,

$P < 0.01$). Parameter estimates obtained for the best model are $h = 0.64$, $c = 0.53$, $\mu = 0.86$, $p = 0.19$, $r = 0.84$ *and* $b = 0.20$, so that 41% of the variance in educational attainment is attributable to additive genetic factors (h^2), 28% to the environmental effects of family background (c^2), and 19% to genotype/environmental covariation ($2hac$), the remaining 13% of the variance being attributable to environmental effects not shared by relatives. Our estimate of the importance of genotype/environmental covariation depends critically on the assumptions made about the mechanisms of environmental transmission and mate selection, which cannot be tested with these data. If we were to make certain alternative assumptions, no genotype/environmental covariation would be predicted[5] and the contribution of the family environment would be estimated at 47%.

For twins born after 1939, we find significant heterogeneity of gene expression and environmental effects across sexes. Purely environmental models are rejected with a high level of significance (1940–49: $\chi^2_{50} = 89.44$, $P < 0.001$; 1950–60. $\chi^2_{53} = 169.55$, $P < 0.001$). Models which allow for both additive gene action and environmental transmission from parent to offspring yield negative estimates for the environmental transmission parameter p, which suggests that any environmental effects of parents on their offspring are being masked by genetic dominance in this design. Models which allow for sex-dependent additive gene action, dominance and environmental effects shared by twins, but no environmental transmission from parent to offspring, give the best fits to these data (1940–49: $\chi^2_{48} = 52.61$, d.f. = 48; $\chi^2_{51} = 56.59$, d.f. = 51). Parameter estimates obtained for this model are, for twins born between 1940 and 1949: $h = 0.70$, $h' = 0.67$, $d = 0.50$, $d' = 0$, $c = 0.29$, $c' = 0.64$, $\mu = 0.72$, $r = 0.82$, $b = 0.31$; and, for twins born between 1950 and 1960: $h = 0.52$, $h' = 0.53$, $d = 0.63$, $d' = 0.32$, $c = 0.45$, $c' = 0.71$, $\mu = 0.73$, $r = 0.82$, $b = 0.40$. These estimates imply that genetic factors (including genetic dominance) account for 74% of the variance in educational attainment in male twins born in 1940–49, and 67% in male twins born in 1950–60, but account for only 45% of the variance in female twins born in 1940–49, and 38% in female twins born after 1949. Conversely, environmental effects shared by twins account for only 8% (1940–49) or 20% (1950–60) of the variance in males, but for 41% (1940–49) or 50% (1950–60) in females. As genetic dominance is a major source of variation in IQ[1–3,22], the absence of evidence for dominance in the pre-1940 sample might be interpreted as evidence against a major influence of IQ on educational attainment in individuals born before 1940. However, dominance may be masked by strong environmental transmission in these data.

The results presented here are clearly consistent with the hypothesis that the importance of genetic influences on educational attainment is subject to secular change. Other explanations of our findings seem implausible. Perhaps more pre-war monozygotic male twin pairs have been misclassified as dizygotic, thus inflating the pre-war dizygotic male correlation? The proportion of pre-war male twins who are dizygotic (45.3%) differs little from the proportion of dizygotic twins in the other twin cohorts (44.4–48.8%). Perhaps a 'special twin environment' effect[23] is involved? As there has been a progressive decrease in the influence of parental educational levels on offspring educational attainment (see Table 1), we would expect the difference between male MZ and DZ twin correlations to have declined rather than increased in recent years. The most likely explanation, confirming the hypothesis of Scarr-Salapatek[8], is that increased educational opportunity has led to an increased dependence of educational attainment on innate ability.

The genetic basis of Haldane's rule

Jerry A. Coyne

Department of Zoology, University of Maryland, College Park, Maryland 20742, USA

'Haldane's rule', formulated by J. B. S. Haldane in 1922, states that: "When in the F_1 offspring of two different animal races one sex is absent, rare, or sterile, that sex is the heterozygous [heterogametic] sex" (ref. 1). His rule is now known to apply in mammals, lepidopterans, birds, orthopterans and dipterans[1–5]. In *Drosophila*, for example, Bock[6] cites 142 cases of interspecific hybridizations that produce one sterile and one fertile sex in the offspring, all but one of these crosses yielding sterile XY males and fertile XX females. Despite much speculation, however, the genetic basis of Haldane's rule remains unknown. Haldane himself rejected the simple explanation that males are innately more sensitive than females to the effects of hybridization because groups with heterogametic females (such as birds and butterflies) usually show female sterility in hybrids, so that heterogamety itself is the critical feature. He and others[1,2,4,7] suggested that heterogametic infertility or inviability in hybrids arises by a genetic imbalance between X chromosomes and autosomes. An alternative explanation[5,8,9] is that this syndrome is caused by a mismatch of X and Y chromosomes. Here I show that in the *Drosophila melanogaster* subgroup, Haldane's rule for fertility apparently arises from a genetic interaction between X and Y chromosomes and not from an imbalance between sex chromosomes and autosomes. This finding has important implications for understanding the evolution of interspecific reproductive isolation.

Haldane's original explanation for asymmetrical sterility or viability rests on the fact that homogametic hybrids have a complete haploid set of chromosomes from each parent, but heterogametic hybrids lack an X chromosome from one of the parental species. The latter hybrids may lack the gene products from both autosomes and sex chromosomes of a complete haploid set which are thought to be necessary for hybrid fertility or viability. The genetic implications of this model are that epistatic interactions between conspecific X chromosomes and autosomes are necessary for proper gene action[7,10]. Alternatively, different species may differ in their linkage relationships; some loci present on the X chromosome of one might be carried on the autosomes of the other. Homogametic hybrids would then have the normal dose of each locus, while heterogametic hybrids would suffer from duplication and deficiencies[11].

One way to test this X-autosome imbalance theory is to produce interspecific hybrid females having both X chromosomes from a single parental species. Because such females will have the same degree of X-autosome mismatch as that of sterile males, they would be expected to be sterile. Only in three species of *Drosophila* (*D. simulans*, *D. mauritiana* and *D. sechellia*) is it possible to carry out such a test, as the three species will hybridize to produce fertile females and sterile males[12–15] and there exists in *D. simulans* a stock with attached X chromosomes. *D. simulans* is cosmopolitan, and *D. mauritiana* and *D. sechellia*

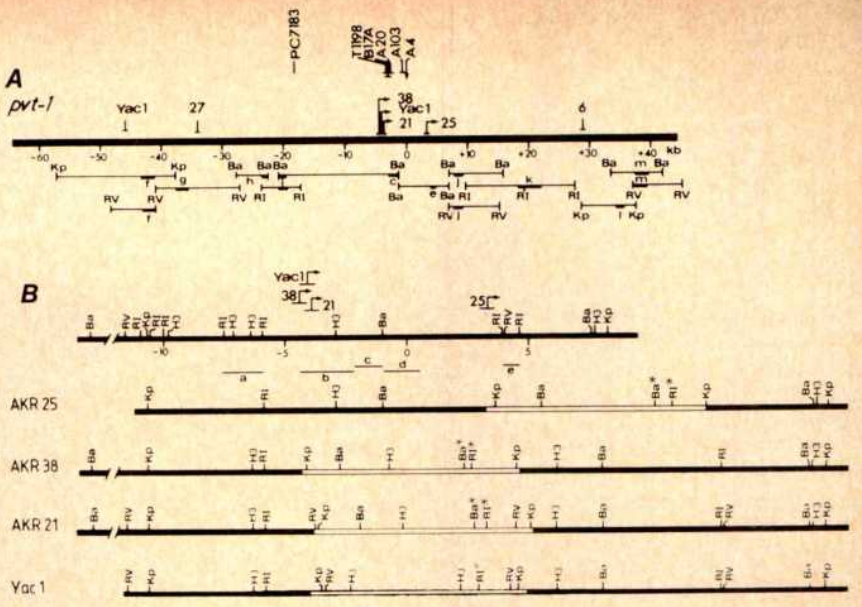

Fig. 1 The *pvt*-1 locus on chromosome 15. *A*, The cloned 108-kb region across the *pvt*-1 locus showing 6; 15 breakpoints in six plasmacytomas (top) and insertions in six T lymphomas; arrows indicate the probable transcriptional orientation of the proviruses, where known. A 17-kb region around the ABPC 4 6; 15 breakpoint is described in ref. 16; complete restriction maps of the clones defining the rest of the locus, the mapping of the four other plasmacytoma 6; 15 breakpoints, and the location of the PC7183 breakpoint described by Van Ness *et al.*[20] within this locus are described elsewhere[17]. Below the bar, the digests and lettered unique-sequence probes (thicker lines) used to survey this region are indicated. An ~1-kb region at +28 kb on the map could not be surveyed with the available probes. Abbreviations for restriction endonuclease sites are: RI, *Eco*RI; Ba, *Bam*HI; RV, *Eco*RV; H3, *Hin*dIII; and Kp, *Kpn*I. *B*, Proviral insertions within the *pvt*-1 locus. This expanded map of the region around the ABPC 4 breakpoint shows the location and orientation (arrows) of proviral inserts in T lymphomas; the bar indicates the possible error (±0.3 kb) in placement of the insertion points and an 8-kb gap has been introduced to save space. Restriction maps for four T lymphomas shown underneath the bar indicate the proviral inserts (open bars); the maps are incomplete, having been deduced by Southern blot analysis of genomic DNA. The *Eco*RI and *Bam*HI sites marked with an asterisk are markers for an MCF *env* region (see text). The probe fragments used for Southern blot analysis were derived from the following digests of cosmid or phage clones (see ref. 17): a and e, EcoRI; b, *Xba*I; c, *Xba*I + *Bam*HI: d, *Bam*HI + *Bgl*II; f, *Bam*HI + *Eco*RI; g, *Kpn*I; h, *Hin*dIII + *Bam*HI; i, *Bam*HI + *Xbaa*I; j, *Kpn*I; k, *Xho*I + *Kpn*I; l, *Xho*I + *Eco*RI; m, *Kpn*I.

not shown). The AKR 25 site, on the other hand, mapped between *c* and *e*. The AKR 25 rearrangement clearly resulted from an insertion, as probes from either side of the recombination site (*c* and *e*) hybridized to the same large rearranged *Hin*dIII fragment (shown for probe *c* in lane 9 of Fig. 2*A*); its size (~19.5 kb) compared with the germline fragment (10.6 kb) is consistent with insertion of ~9 kb of DNA lacking a *Hin*dIII site. Data obtained for the other three lines using flanking probes are consistent with the presence of a 9-kb insert bearing one *Hin*dIII site and one *Eco*RI site. Additional results from *Bam*HI, *Eco*RV and *Kpn*I digests allowed us to deduce the maps shown in Fig. 1*B*. The number of retroviral inserts in these tumours (see below) precluded using retroviral probes to verify that the inserts are proviruses, but all the data are consistent with that conclusion. The size of the inserts is that of a full-length (replication-competent) provirus, and the *Kpn*I sites found near both ends of each insert are almost invariant markers of murine proviral long terminal repeats (LTRs). The *Kpn*I (and *Eco*RV) sites associated with LTRs allowed us to localize the inserts more precisely. The AKR 38, AKR 21 and Yac-1 inserts fall within a ~1-kb region located only ~1 kb from three of the 6; 15 translocation breakpoints, while the AKR 25 insertion site lies 3 kb to the right of the ABPC 4 breakpoint (Fig. 1*A*). Thus, four retroviral inserts and five plasmacytoma breakpoints map within an 8-kb region.

Significantly, the four inserts have features characteristic of the MCF proviruses strongly implicated in leukaemogenesis[24]. Like most MCF inserts found near c-*myc*[7], all four bear an *Eco*RI site ~2 kb from one end and the three AKR inserts have a nearby *Bam*HI site (Fig. 1*B*). These hallmarks of the *env* region (encoding the glycoprotein region gp70) of a leukaemogenic MCF virus are acquired by recombination with endogenous non-ecotropic proviruses[24,27-30]. The hybrid gp70 is thought to promote leukaemogenesis by permitting retroviral invasion of thymocytes and/or providing them with a mitogenic stimulus[24]. As the *env* gene lies downstream of the viral *gag* and *pol* genes, all four proviral inserts would be transcribed from left to right on the maps in Fig. 1.

The three other rearrangements lie farther from the plasmacytoma breakpoints (Fig. 1*A*); although we lack sufficient unique-sequence probes in the relevant flanking regions to characterize them extensively, it seems likely that they also reflect proviral integration. The putative insert in AKR 6 maps ~29 kb to the right of the ABPC 4 translocation site (Fig. 1*A*), assuming that the acquired *Kpn*I site (Fig. 2*B*) lies within an LTR, while that in AKR 27 maps ~16 kb to the left of the PC7183 translocation breakpoint. Curiously, Yac-1 appears to have an additional insert still farther from the PC7183 site (Fig. 1*A*). The apparent presence of two inserts within *pvt*-1 in Yac-1 may reflect selection for further insertions during its long passage history.

Retroviral insertion within *pvt*-1 is unlikely to be coincidental, as insertion is thought to be random[31] and the 100-kb region surveyed here represents only 3.7×10^{-5} of the genome. Given ~10 inserts per AKR tumour (ref. 28 and our unpublished results), the chance of finding a single random insert within that

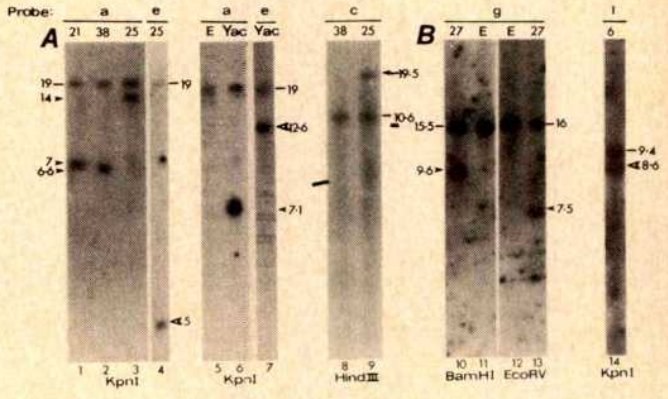

Fig. 2 Southern blots revealing *pvt*-1 rearrangements in T lymphomas. *A*, Rearrangements in the region favoured for 6; 15 translocations; *B*, more distant rearrangements. E denotes AKR embryonic DNA. Fragment sizes are in kilobases (kb). Bars indicate fragments from the unrearranged allele; solid arrowheads mark left-hand host–viral junction fragments, while open arrowheads indicate right-hand junction fragments. The *Bam*HI fragment analysed in lanes 10 and 11 spans from ~−42 to −28 kb on the map in Fig. 1*A*. Letters denote probes described in Fig. 1 legend. The methods used for preparation of DNA of high relative molecular mass, its digestion by the indicated restriction endonucleases, subsequent electrophoretic fractionation, hybridization and autoradiography have been detailed elsewhere[21,26].

region in the 33 tumours analysed is $\sim 10 \times 33 \times 3.7 \times 10^{-5} = 0.01$, and the odds of finding seven inserts by chance are $\sim (10^{-2})^7 = \sim 10^{-14}$. The possibility that *pvt*-1 is merely a preferred integration region, unrelated to oncogenesis, seems unlikely because chromosome 15 has not acquired endogenous proviruses[32], nor is *pvt*-1 merely a recombination 'hotspot', because translocations involving this band have not been associated with non-lymphoid tumours. Hence, it seems likely that the insertions contributed to T-lymphoma development. Whether *pvt*-1 is related to any of the previously identified retroviral insertion regions[11-13] is not yet clear; it does not correspond to *pim*-1, a common locus of M-MuLV insertion in murine T lymphomas[13], because their restriction maps differ markedly and *pim*-1 does not map to chromosome 15 (A. Berns, personal communication). Conceivably, *pvt*-1 may bear the murine homologue of one of the three common proviral insertion loci identified in rat thymomas (*mlvi*-1, *mlvi*-2 and RMoInt-1)[11,12]. Both *mlvi*-1 and *mlvi*-2 have homologues on mouse chromosome 15 (refs 14, 15), but that of *mlvi*-2 does not appear to map to the distal region of chromosome 15 (ref. 14), where *myc* and *pvt*-1 lie[4,18,19].

As the *pvt*-1 breakpoints lie at least 72 kb from the c-*myc* promoters[17], it is conceivable that *pvt*-1 bears another oncogene, but we have found no evidence that it bears sequences related to known oncogenes[17]. In particular, the putative mammary oncogene *int*-1 (ref. 33) and the c-*sis* gene, which both map to chromosome 15 (refs 33, 34), were not detected within the entire cloned *pvt*-1 (or c-*myc*) regions; we found no rearrangements near *int*-1 or *sis* when we screened *Eco*RI digests of the 32 AKR tumour DNAs with *int*-1 probe *c* (see ref. 33), provided by Drs H. Varmus and T. Fung, and a v-*sis* probe.

To determine whether *pvt*-1 is transcriptionally active, we used probes from the region near the major insertion/breakpoint region (from −11 kb to +4.8 kb on the map in Fig. 1*B*) to examine blots of poly(A)$^+$ RNA from several T lymphomas and plasmacytomas; only low levels of transcripts were found and none was consistently elevated (or depressed) in lines having *pvt*-1 alterations compared with those lacking any *pvt*-1 rearrangement (ref. 17 and J.A., unpublished results). Thus we have not yet found an attractive candidate for a *pvt*-1 gene that might be a target for the insertions and translocations.

Is retroviral insertion within the *pvt*-1 locus associated with active c-*myc* expression, as are the variant (6; 15) plasmacytoma translocations involving *pvt*-1 (refs 17, 19) and the variant Burkitt lymphoma translocations[35-39]? To address this question, we compared messenger RNAs from four T-lymphoma lines having *pvt*-1 inserts, six AKR lines having inserts near c-*myc*[7] and four AKR lines lacking detectable inserts within either locus. Nearly all the lines had comparable levels of the canonical ~2.4-kb c-*myc* mRNA (Table 1, Fig. 3). These levels fall within the range found in plasmacytomas bearing either the 6; 15 or 12; 15 translocation[17,19,40-44] (illustrated respectively by ABPC4 and TEPC609 in Fig. 3) and are well above the range observed in normal lymphoid tissues or in most chemically induced T lymphomas examined previously[40]. These results suggest that c-*myc* is activated in most retrovirally induced T lymphomas. In tumours with a provirus close to *myc*[7-10], activation is probably mediated by the LTR enhancer, which frequently disrupts putative control sequences upstream from *myc*[7]. We speculate that insertions within *pvt*-1, and perhaps yet other loci, can also activate c-*myc*, either directly or indirectly (see below). Of the 35 retrovirally induced T lymphomas we have studied, 9 AKR tumours and 2 T lymphomas induced by Soule MuLV had insertions near c-*myc* (ref. 7 and Table 1), and 6 had insertions within *pvt*-1 (Fig. 1*A*).

Our results suggest that alterations of *pvt*-1 may be conducive to T-cell as well as B-cell neoplasia, perhaps by inducing constitutive c-*myc* expression. As cloned sequences from the *pvt*-1 and c-*myc* loci establish that *pvt*-1 alterations occur at least 72 kb from the c-*myc* promoters[17], how might the effect be conveyed over such large distances? The 6; 15 translocations couple the left-hand side of the *pvt*-1 locus to the C_κ enhancer[16,17,20] and the insertions presumably introduce the LTR

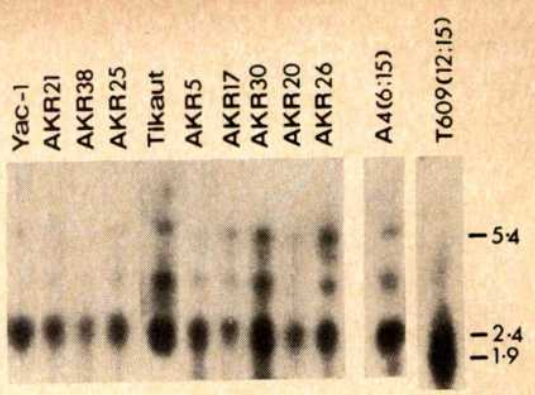

Fig. 3 Transcripts of the c-*myc* gene in 10 T lymphomas and 2 plasmacytomas. Blots were hybridized with a *myc* exon 3 probe (a *Sac*/*Xho* fragment)[41]. RNAs in the first four lanes derive from T lymphomas which have proviral inserts within *pvt*-1, while those in the second four lanes are from T lymphomas with inserts near c-*myc*[7]; AKR 20 and 26 have no inserts near c-*myc* or *pvt*-1 (Table 1). Plasmacytoma ABPC 4 (A4) has a t(6; 15) and contains the standard ~2.4-kb transcripts[17,19], while TEPC609 has the typical C_α-*myc* t(12; 15) fusion and yields only the 1.8–2.2-kb mRNAs derived from the rearranged gene[41]. The ~5.4-kb RNA is a nuclear precursor of the 2.4-kb mRNA[41]. Poly(A)$^+$ RNA was prepared by a method[45] involving lysis of tumour tissue in SDS and proteinase K, followed by oligo(dT)-cellulose chromatography. RNA was denatured by heating for 10 min at 60 °C in formaldehyde, and 3 μg was fractionated on a 1.5% agarose gel in formaldehyde and transferred to nitrocellulose[46].

Table 1 T-lymphoma insertions and c-*myc* expression

Tumours denoted AKR arose spontaneously in mice 7–12 months old in our AKR mouse colony[7]. Tikaut is a cell line derived from an AKR tumour[27] and Yac-1 a cell line derived from a M-MuLV induced BALB/c tumour[22]. Tikaut is trisomic[25], but no cytogenetic data are available on the other lines.

* Insert detected within a 53-kb region across c-*myc* described elsewhere[17], extending from 27 kb 5′ to the c-*myc* promoters to 26 kb 3′ of them. All 5′ inserts map within 2 kb of the c-*myc* promoters[7]. The insert in AKR 30 maps ~24 kb 3′ of the c-*myc* promoters[7], and that in AKR 14 in the same vicinity (unpublished results), while that in AKR 2 appears to be in the 3′-untranslated portion of exon 3 (ref. 7).

† Insert detected within the 108-kb cloned region across *pvt*-1 (see Fig. 1*A*).

enhancer (and promoter), but enhancers are generally thought to act over distances of only 5–10 kb. Conceivably, the translocations/insertions may alter a *pvt*-1 gene that regulates *myc* expression, either disrupting a negative regulator or stimulating expression of a positive regulator, although we have not yet found a *pvt*-1 transcript that is consistently depressed or stimulated by the *pvt*-1 alterations. Alternatively, the effect may be conveyed along the chromosome (in *cis*) by disruption of long-range chromatin folding, although such effects might not be expected from a 9-kb insert. For either model, it is tempting to think that *pvt*-1 is involved in normal *myc* regulation.

We thank Jan Mitchell, Linda Byrt and Leonie Gibson for technical assistance and Lynn Corcoran, Tom Gonda, Ora Bernard and Elizabeth Webb for discussions. A novel serine esterase expressed by cytotoxic T lymphocytes

Mark S. Pasternack*† & Herman N. Eisen*‡

*Department of Biology and Center for Cancer Research, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139, USA
†Children's and Medical Services (Infectious Disease Units), Massachusetts General Hospital, and the Department of Pediatrics, Harvard Medical School, Boston, Massachusetts 02114, USA

Cytotoxic T (T_c) lymphocytes recognize and lyse target cells and are thought to serve as an important defence against viral infections[1] and possibly against neoplasms[2]. The nature of the receptors responsible for antigen recognition by these cells is becoming clearer, but the molecular mechanisms responsible for their cytolytic activity remain largely unknown. The possibility that proteases are involved in this process has been suggested by the effects of certain inhibitors[3,4]. Here we demonstrate that clones of murine T_c cells possess considerable trypsin-like esterase activity when assayed by a sensitive colorimetric assay. This activity was blocked completely by two serine esterase inhibitors, diisopropylfluorophosphoridate (DFP) and phenylmethylsulphonyl fluoride (PMSF), but not by N^{α}-tosyl lysyl chloromethyl ketone (TLCK). The use of ^{3}H-DFP as an affinity-labelling reagent demonstrated that the esterase activity resides in a protein of relative molecular mass (M_r) 28,000 (28K). A wide variety of other lymphocytes, including those from thymus, spleen and lymph node, established lines of B cells and noncytotoxic T cells, and clones of T helper cells, had about 300-fold less esterase activity than the T_c-cell clones and far smaller amounts of the DFP-reactive 28K protein. However, in thymocytes the esterase activity increased 20–50-fold and the 28K protein became more prominent 4 days after these cells had been stimulated *in vitro* to generate T_c cells.

Previous investigations have demonstrated that the lytic activity of both T_c cells[3,4] and natural killer cells[5–7] is reduced by exposure to certain protease inhibitors. In an attempt to characterize T_c-cell proteases directly, extracts of G4 cells, a clone of BALB.B anti-H-2D^d T_c cells[8], were prepared in phosphate-buffered saline (PBS) containing 0.5% Nonidet P-40 (NP40). Trypsin-like esterase activity in the lysate was assayed spectrophotometrically using a sensitive coupled reaction involving N^{α}-benzyloxycarbonyl-L-lysine thiobenzyl ester

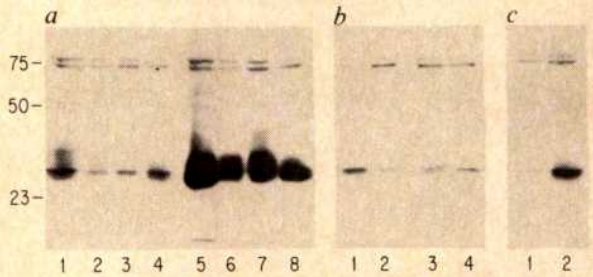

Fig. 1 Affinity labelling of serine esterase with ^{3}H-DFP. *a*, Affinity labelling of T_c cells. Three million T_c cells were labelled directly (lanes 1–4) or following solubilization in NP40-PBS (lanes 5–8). Lanes 1, 5, G4; lanes 2, 6, B10; lanes 3, 7, 1.5.2; lanes 4, 8, cr 15 (2 days exposure). *b*, Affinity labelling of T_h-cell extracts. Three million cell equivalents were analysed. Lane 1, O_3; lane 2, D_5; lane 3, A_6A_2; lane 4, BW5147 (3 days exposure). *c*, Affinity labelling of thymocyte extracts. Six million cell equivalents were analysed. Lane 1, resting thymocytes; lane 2, thymocytes incubated for 4 days in Con A supernatant and Con A (3 days exposure). M_r standards ($\times 10^{-3}$) are shown on the left.

Methods. [1,3-^{3}H]DFP in propylene glycol (5.2 Ci mmol^{-1}; NEN) was added to 300 μl of various cell extracts in NP40-PBS as described in Table 1 to a final concentration of 10^{-5} M. After 30 min incubation at 37 °C, the reaction was stopped by adding Tris-HCl *p*H 8.1, to a final concentration of 15 mM and SDS to a final concentration of 0.1%. Samples were centrifuged at 8,000*g* for 15 min. The pellets were discarded, the supernatants were concentrated to 100–150 μl and the labelled proteins recovered by cold acetone precipitation. The protein pellet was dissolved in sample buffer containing 5% mercaptoethanol and analysed by electrophoresis on a 10% polyacrylamide gel in the presence of 0.1% SDS (ref. 19). Gels were impregnated with Autofluor (National Diagnostics, Somerville, New Jersey), dried and exposed for the indicated times at −70 °C using XAR-5 film (Eastman Kodak).

Cell preparations containing non-viable stimulator cells or complement-lysed cells were passed over Ficoll-Hypaque gradients (Pharmacia) to remove dead cells before extraction of the viable cells. G4 cells, which are adherent, were collected by brief exposure to EDTA (5 mM in PBS) after decanting stimulator cell debris; they were not purified further. Cells were washed twice in fresh medium, twice in PBS or in RPMI 1640 containing 100 $\mu g\ ml^{-1}$ bovine serum albumin (5 × recrystallized; Boehringer-Mannheim), counted, washed a third time in PBS, then lysed by incubating $1-2\times10^7$ cells ml^{-1} in PBS containing 0.5% NP40 (Particle Data Laboratories, Elmhurst, Illinois) for 20-30 min on ice with frequent vortexing. Esterase activity in the lysates was measured by adding 900 μl of a reaction mixture (0.2 M Tris-HCl *p*H 8.1, 2×10^{-4} M BLT (Calbiochem-Behring), 2.2×10^{-4} M dithiobis (nitrobenzoic acid); (Sigma)) to 100 μl of appropriate dilutions of cell extracts in NP40/PBS. After 30 min at room temperature, the absorbance at 412 nm was measured in a Gilford spectrophotometer using 100 μl 0.5% NP40 in PBS plus 900 μl of the reaction mixture as a blank; an absorbance of 1.0 was defined as 1 unit of esterase activity. The cell extracts were prepared from (1) G4, a BALB.B anti-H-2D^d T_c-cell clone (ref. 8); (2) G4 grown in recombinant human IL-2; (3) B10, a BALB.B anti-H-2L^d T_c-cell clone (ref. 8); (4) 1.5.2, a BALB.B anti-H-2L^d T_c-cell; (5) cr 15, a (B10.BR × B10.D2)F_1 anti-BALB minor T_c-cell clone (ref. 15); (6) O_3, a BALB/c T_H-cell clone specific for ovalbumin plus Ia^d (ref. 16); (7) D_5, a (BALB/c × A/J)F_1 T_H-cell clone specific for arsanilated protein plus Ia^d (ref. 17); (8) A_6A_2, a T_H-cell hybridoma of B10.A origin fused with BW5147, specific for hen egg lysozyme (provided by Dr L. Glimcher, manuscript in preparation); (9) EL-4, a T-cell leukaemia of C57BL/6 origin; (10) EL-4 maintained in 10% rat spleen cell Con A supernatant (RCASUP); (11) BW5147, T-cell lymphoma of AKR origin; (12) BW5147 maintained in 10% Con A supernatant; (13) BW5147 maintained in 10% Con A supernatant and 10 $\mu g\ ml^{-1}$ Con A; (14) P815, mastocytoma of DBA/2 origin; (15) thymocytes collected from 3-week-old BALB/c females; (16) thymocytes cultured for 4 days with 10% Con A supernatant and 10 $\mu g\ ml^{-1}$ Con A (ref. 10); (17) BALB/c spleen cells following lysis of erythrocytes with NH_4Cl; (18) BALB/c spleen cells depleted of T cells by treatment with two anti-Thy-1 monoclonal antibodies and rabbit complement; (19) BALB/c spleen cells cultured for 4 days with *Salmonella typhosa* lipopolysaccharide (LPS, Difco) at 10 $\mu g\ ml^{-1}$, then depleted of T cells with anti-Thy-1 before assay; (20-22) B-cell clones of CBA/N mice[18]. For the inhibition studies, an aliquot of G4 extract was incubated for 30 min at 37 °C with DMSO, or DMSO containing the indicated serine esterase inhibitors. Percentage inhibition = (1 − absorbance of treated samples/absorbance of control sample) × 100. (23) G4 extract pretreated with 2 mM DFP; (24) G4 extract pretreated with 2 mM PMSF; (25) G4 extract pretreated with 5×10^{-4} M TLCK.

(BLT) as described by Green and Shaw[9]; hydrolysis yields benzyl mercaptan, which reacts with Ellman's reagent to produce the thiophenoxide chromophore (Table 1). The esterase activity, equivalent to ~1 μg of trypsin per 10^6 cells, was not restricted to G4, as three other T_c-cell clones (B10, 1.5.2 and cr 15), of two different specificities, had roughly comparable activity (Table 1).

Because all of the T_c-cell clones had been maintained in long-term culture in medium containing 10% rat spleen cell concanavalin A (Con A) supernatant and stimulator cells, it was important to assay the stimulator cells and a variety of other cell lines. Table 1 summarizes the BLT-esterase activities in NP40 extracts of several different noncytotoxic cell lines. The cells used as stimulators to maintain the cultured T_c-cell clones (BALB/c spleen cells and *in vitro* passaged P815) possessed little activity. Two T-cell tumour lines, EL-4 and BW5147, also had minimal activity. Furthermore, when these T-cell lines were maintained in medium containing 10% Con A supernatant (or when BW5147 was incubated with both 10% Con A supernatant and 10 $\mu g\ ml^{-1}$ Con A) there was no significant increase in enzyme activity. Thus, the presence of stimulator cells and conditioned medium as sources of adsorbed esterase activity could not be invoked as trivial explanations.

Two additional experiments confirmed the endogenous character of the esterase activity in T_c cells. First, there was no difference between the esterase activity in G4 cells that had been serially cultured twice in recombinant human interleukin-2 (IL-2, a generous gift of Biogen) and in cells cultured continuously in 10% Con A supernatant. Second, and more interestingly, two T-helper (T_h) cell clones, O_3 and D_5, which lacked cytotoxic activity and had been maintained in long-term culture with 10% Con A supernatant and intermittently stimulated with antigen-pulsed spleen cells, had negligible activity (Table 1). A T_h-cell hybridoma, A_6A_2, also showed only traces of activity (Table 1). Thus, among all B and T lymphocytes tested, a high level of esterase activity was expressed only in T_c cells.

To determine whether the esterase activity in T_c-cell clones represented some unusual adaptation of these cells to long-term culture, we studied the expression of esterase activity in T_c cells generated by short-term culture of precursor cells. For this purpose, thymocytes were incubated in culture medium containing rat spleen cell Con A supernatant and Con A[10]. After 4 days, viable thymocytes showed a level of lectin-dependent cytotoxic activity (2-4 lytic units (LU_{50}, see Fig. 2 legend) per 10^6 cells)[11] that was comparable to that seen in conventional mixed lymphocyte cultures, and extracts of these thymocytes showed an approximately 50-fold increase in BLT-esterase activity (see Table 1).

The T_c-cell esterase activity was completely inhibited by the irreversible serine esterase inhibitors DFP and PMSF (Table 1), suggesting that this activity is due to a serine esterase, but it was not inhibited by TLCK, a trypsin inhibitor known to block T_c-cell cytotoxicity and to react with the surface glycoproteins T200 and LFA-1 (refs 3, 4, 8). Using ^{3}H-DFP as an affinity-labelling reagent[12] to characterize the esterase further (Fig. 1), we found that although minor ^{3}H-labelled components occurred at M_r 76,000 and 71,000, a prominent ^{3}H-DFP-reactive component was present at M_r 28,000. Moreover, whereas the higher-M_r moieties were present at about the same low level in all lymphoid cells tested, the level of the 28K component clearly

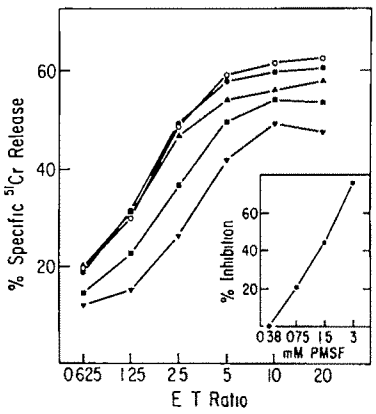

Fig. 2 Inhibition by PMSF of specific target cell lysis by T_c-cell clone G4. E:T, effector to target ratio. The G4 cells were suspended in complete medium at $\sim 5\times10^6$ ml^{-1} and DMSO (control) or PMSF dissolved in DMSO was added (final DMSO concentration 3%). ○, Control with DMSO alone, ●, 0.375 mM PMSF; ▲, 0 75 mM PMSF; ■, 1 5 mM PMSF; ▼, 3 mM PMSF. Inset: Results expressed as a dose-response curve. One lytic unit (LU_{50}) is the number of T_c cells required for 50% specific lysis of 1×10^4 ^{51}Cr-labelled P815 cells. Percentage inhibition = $(1-LU_{50}$ in the presence of PMSF/LU_{50} in the absence of PMSF) $\times 100$.
Methods. The cells were incubated with PMSF (or DMSO as control) for 30 min at 37 °C, washed, counted and diluted for titration of cytotoxic activity against 1×10^4 ^{51}Cr-labelled P815 cells. Recovery of G4 was comparable for all the treated samples. In some experiments, DMSO alone was responsible for ~10–15% ^{51}Cr release from labelled G4 cells, but the presence of PMSF at the concentrations shown had no additive toxicity measured either by ^{51}Cr release or by reduced recovery of viable (trypan blue-negative) G4 cells. T_c-cell assays were performed as described previously[20].

varied with the level of the BLT-esterase activity; both were pronounced in extracts of T_c-cell clones (Fig. 1*a*, lanes 5–8), but present in only trace amounts in noncytotoxic cells (Fig. 1*b*, lanes 1–4); and both increased after inducing T_c-cell activity in thymocytes by incubation with Con A (Fig. 1*c*, lanes 1, 2). Further evidence linking the BLT-esterase activity to the 28K component has emerged from their co-purification through affinity chromatography and an ion-exchange column (M. S. Pasternack *et al.*, manuscript in preparation).

If BLT-esterase is necessary for target cell lysis, inhibition of the esterase should block the cytolytic reaction. DFP was not tested because propylene glycol, the solvent in which it is kept, is toxic to cells, but PMSF at nontoxic concentrations clearly inhibited lysis of P815 (H-2^d) cells by the cloned anti-D^d G4 cells (Fig. 2). Note, however, that although PMSF at 2 mM blocked the esterase activity in lysates completely, at 1.5 mM it blocked only 50% of the T_c-cell cytolytic activity (Table 1, Fig. 2). Similarly, ^{3}H-DFP labelled the 28K component intensely in T_c-cell lysates, but only weakly in intact T_c cells (Fig. 1*a*, compare lanes 1–4 with 5–8). The difference between lysed and intact T_c cells raises several possibilities: one is that the BLT-esterase, or at least its active site, is normally located intracellularly, rather than on the cell surface, and is thus only poorly accessible to the added esterase inhibitors; another is that the esterase exists in intact cells as an inactive zymogen until converted into an active enzyme by another protein, perhaps a member of a complement-like cascade. In this connection, it is of interest that structures resembling the aggregated C9 component of complement have recently been described in cytolytic cells (T_c cells and natural killer cells)[13,14]. We believe the BLT-esterase described here represents the first enzymatic difference reported between cytotoxic and noncytotoxic T cells.

We thank Michael Bevan for cr 15 cells, Jonathan Braun for B-cell clones, Rosemarie DeKruyff for T_h cells O_3 and D_5, Laurie Glimcher for hybridoma A_6A_2, and David Kranz and David Sherman for clone 1.5.2. We also thank Ann Hicks for assistance in the preparation of this manuscript. This work was supported by research grants (CA-15472 and CA-28900) and a Cancer Center Core Grant (CA-14051) from the National Cancer Institute.

Note added in proof: Preliminary results suggest that cloned T cells having both the helper phenotype (L3T4$^+$, Lyt-2$^-$, antigen-dependent IL-production) and exhibiting Con A-dependent cytotoxic activity may also have elevated serine esterase activity. Thus it is possible that the serine esterase level correlates with cytotoxic activity *per se*, rather than with the surface glycoprotein markets that classically distinguish helper (T_H) and cytotoxic (T_c) cells.

Reversible activation of non-steroid binding oestrogen receptor

William J. Raymoure*, Reid W. McNaught* & Roy G. Smith*†

Roy and Lillie Cullen Department of Urological Research, Departments of *Urology and †Cell Biology, Baylor College of Medicine, 1 Baylor Plaza, Houston, Texas 77030, USA

Two high-affinity oestrogen receptors have been identified in the chick oviduct with equilibrium dissociation constants (K_d) of 0.1 and 1 nM, differing in their binding kinetics, role in ovalbumin synthesis and independent regulation *in vivo*. The higher-affinity receptor (X) increases RNA polymerase II activity directly[1], whereas the low-affinity receptor (Y) seems to be necessary to confer specificity to transcription of oestrogen-dependent genes[2]. Acute administration of progesterone to oestrogen-stimulated chicks results in preferential destruction of the nuclear Y receptor[3] accompanied by interruption of ovalbumin gene transcription[4]. Here we demonstrate that receptor Y exists in a non-oestradiol binding form (Y_{nb}) which can be activated to the binding form *in vitro* by treatment with either ATP or ADP. Furthermore, dialysis of oviduct cytosol, which has no effect on the high-affinity receptor X, converts receptor Y to Y_{nb}; receptor Y can then be recovered by treatment with ATP in the presence of Mg^{2+} and independently of Ca^{2+}. This is the first report of the controlled interconversion between a non-steroid binding form of oestrogen receptor and active receptor in a tissue that contains two independently regulated oestrogen receptor types.

Oestrogen receptor augmentation by incubation with nucleotides has been reported by Fleming *et al.*[5] and Auricchio *et al*[6]. However, the affinity and steroid specificity of the induced binding sites were not examined. The characteristics of the heterogeneity of oestrogen receptors described in the chick oviduct[7–9] are different from the oestrogen-binding proteins of the rat uterus[10]. To avoid comparisons with the rat uterine types I and II oestrogen-binding proteins, the two oviduct receptors have been designated X ($K_d = 0.1$ nM) and Y ($K_d = 1$ nM).

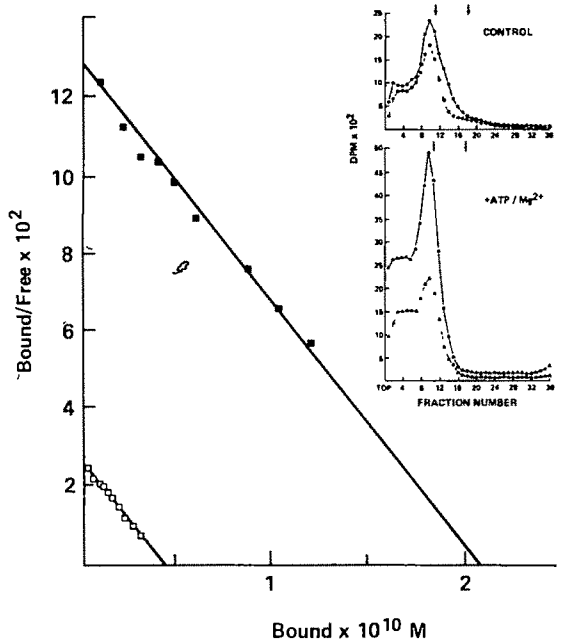

Fig. 1 Effects of ATP on the Y-receptor type. Week-old white Leghorn chicks were stimulated for 14 days with diethylstilboestrol in sesame oil and withdrawn for 1–2 days. Oviducts were removed into ice-cold saline and homogenized in TESH buffer (10 mM Tris, 1 mM EDTA, 12 mM thioglycerol, *p*H 7 4) in a ratio of 1/5 (w/v) and centrifuged at 1,000*g* for 20 min. Cytosol was obtained from the supernatant by centrifugation at 100,000*g* for 90 min. Binding assays used a range of ^{3}H-E_2 of 80 pM–10 nM and included 10 mM Na_2MoO_4 to stabilize the binding form of the receptor Nonspecific binding was assessed by addition of 100-fold excess diethylstilboestrol to duplicate tubes. Assays were incubated for 3 h at 30 °C, then for 18 h at 4 °C, unbound steroid was separated by addition of dextran-coated charcoal[4] and data analysed according to Scatchard[14] □—□, Control assay ($K_d = 1.5$ nM; $n = 0.43 \times 10^{-10}$ M), ■- - - -■, inclusion of 2.5 mM ATP and 2.5 mM $MgCl_2$ in the assay ($K_d = 1.6$ nM; $n = 2.0 \times 10^{-10}$ M). Insets Sucrose density gradient analysis. Aliquots of cytosol used in binding assays were labelled with 5 nM ^{3}H-oestradiol alone or with the addition of 2.5 mM ATP and 2.5 mM $MgCl_2$ at 30 °C for 3 h then at 4 °C for 18 h to augment receptor Y. Nonspecific binding was assessed by the inclusion of 100-fold molar excess unlabelled diethylstilboestrol. Unbound steroid was removed by the addition of dextran-coated charcoal immediately before the cytosol was applied to linear gradients containing 5–20% sucrose (w/v) with 400 mM KCl. Gradients were centrifuged for 9 h at 200,000*g* with ^{14}C-ovalbumin (3.6S) and ^{14}C-amylase (8.2S) included as internal standards Upper inset: Control; total bound (●- - - -●); nonspecific (○- - - -○). Lower inset: Augmented Y, total bound (▲—▲); nonspecific (△—△).

Oviduct cytosol, which contained low concentrations of receptor Y only, was obtained from chicks chronically stimulated with diethylstilboestrol for 14 days and then withdrawn for 1–2 days. Treatment of this cytosol with 2.5 mM ATP and 2.5 mM $MgCl_2$ in the presence of oestradiol at 30 °C for 3 h caused a large increase in the receptor concentration, as illustrated by Scatchard and sucrose density analyses (Fig. 1). This amplification was of a comparable degree when ADP was substituted for ATP, whereas GTP had a lesser effect. Both ATP with an ATP regenerating system (creatine kinase and creatine phosphate) and ADP with an ADP trap (creatine kinase and creatine) were effective. Incubation with the blocked ATP and ADP derivatives β,γ-methyleneadenosine 5′-triphosphate (AMP-PCP) and α,β-methyleneadenosine 5′-diphosphate (AMP-CP) did not increase the concentrations of Y, whereas α,β-methyleneadenosine 5′-triphosphate (AMP-CPP) was as potent as either ATP or ADP. Neither cyclic AMP nor cyclic GMP in the presence of isobutylmethylxanthine converted Y_{nb} to Y, nor did they alter the ATP effect. The conversion of Y_{nb} to Y by ATP was dependent specifically on Mg^{2+}, with an optimum concentration of 2–5 mM. Mn^{2+} was ineffective and, in contrast to the observations of Auricchio *et al.*[6], Ca^{2+} was ineffective and did not synergize the effect of Mg^{2+}. The augmentation did not occur in cytosol obtained from oviducts withdrawn from diethylstilboestrol for >3 days when a high concentration of X, as well as Y, was present. The data shown in Table 1 demonstrate that the augmented receptor has steroid specificity typical of oestrogen receptors.

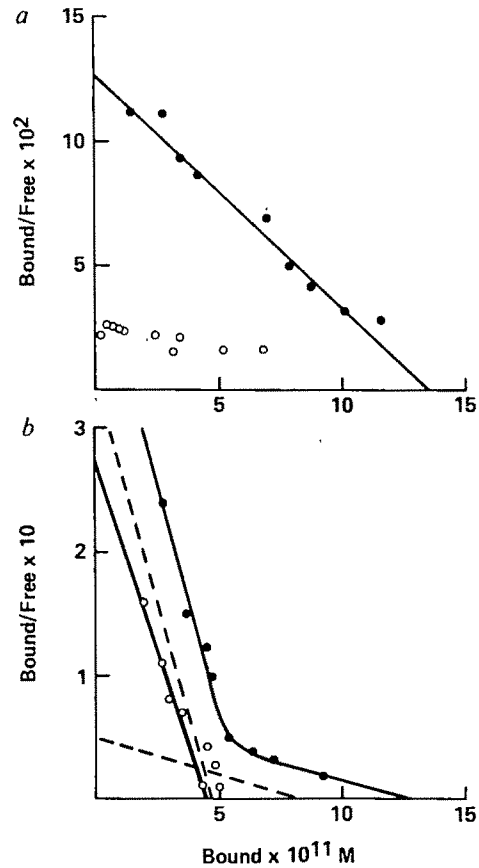

Fig. 2 Preferential effects of dialysis on the Y-receptor type. Chick oviduct cytosol was prepared, assayed and analysed as described in Fig 1 *a*, Oviduct cytosol from chicks withdrawn from diethylstilboestrol for 3 days containing the Y-receptor type only. Closed circles indicate control assay ($K_d = 1.1 \times 10^{-9}$ M, $n = 13.3 \times 10^{-11}$ M), open circles denote dialysis of cytosol for 24 h *b*, Oviduct cytosol from chicks withdrawn from diethylstilboestrol for 5 days containing both X- and Y-receptor types. Closed circles, control assay, dashed line, Rosenthal projection[15] of data; $K_dX = 0\,13 \times 10^{-9}$ M, $n = 4.3 \times 10^{-11}$; $K_dY = 1.5 \times 10^{-9}$ M, $n = 7\,9 \times 10^{-11}$ M; open circles, assay data from cytosol after dialysis for 24 h as in Fig. 1. $K_dX = 0\,13 \times 10^{-9}$ M, $n = 4.3 \times 10^{-11}$ M.

The Y-receptor concentration can be reduced selectively by dialysis (Fig. 2). Oviduct cytosol containing only the Y-receptor type was obtained from chicks withdrawn from diethylstilboestrol after 2 days. After this cytosol was dialysed for 24 h against TESH buffer (see Fig. 1 legend), oestrogen receptor was no longer detectable (Fig. 2*a*). Cytosol from chicks withdrawn from diethylstilboestrol for longer times (3–5 days) with both the X and Y receptors was also dialysed; no effect was observed on receptor X, whereas Y was decreased preferentially to undetectable levels (Fig. 2*b*).

Evidence for the reversible *in vitro* conversion of Y to Y_{nb} is presented in Table 2. Dialysis of cytosol caused a complete loss of the Y-receptor type. When dialysed cytosol was treated with ATP and $MgCl_2$, there was essentially quantitative recovery ($97.8 \pm 1.1\%$, $n = 3$) of the Y receptor. Treatment of dialysed cytosol with either $MgCl_2$ or ATP alone did not restore lost binding activity.

This study provides the first evidence that the chick oviduct oestrogen receptor Y exists in a non-oestradiol binding form, Y_{nb}, and that these two forms can interconvert; dialysis of cytosol favours Y_{nb}; Y_{nb} can be converted to Y at 30 °C in the

Table 1 Specificity of oestradiol binding to receptor Y after augmentation with ATP

Steroid (100 nM)	^{3}H-Oestradiol bound (pM) (% inhibition)
None	235 59 (0)
Oestradiol	124.77 (47.0)
Oestriol	163 43 (30.6)
Diethylstilboestrol	130.42 (44.7)
Progesterone	229.14 (2.7)
Testosterone	228.74 (2.9)
Dihydrotestosterone	227.79 (3.3)
Cortisol	236.06 (0)
Triamcinolone acetonide	237.82 (0)

Single-point (1 nM ^{3}H-oestradiol (E_2)) binding assays were performed in the presence of various unlabelled steroids in conditions of receptor augmentation as described in Fig 1 legend

presence of $MgCl_2$ and ATP, ADP or GTP. The Mg^{2+}-dependence of this conversion, the requirement of a hydrolysable terminal phosphate group for blocked nucleotide analogues to elicit conversion and the ineffectiveness of cyclic nucleotides (even with added ATP) suggest that a non-cyclic-nucleotide-mediated phosphorylation is involved. That both ATP and ADP, together with their regenerating and trap systems, respectively, augment receptor activity suggests that either ATP or ADP can donate the necessary phosphate group. The reversibility of this conversion (Table 2), the lack of receptor augmentation with the hydrolysis-resistant ATP and ADP derivatives and the effectiveness of ATP with regenerating system, eliminates the possibility that these observations are an ADP-mediated protection against heat loss, as has been suggested for glucocorticoid receptors[11].

We have been unable to observe the non-oestrogen binding form of the receptor in oviduct cytosol preparations from either chronically stimulated or long-term (>3 days) oestrogen-withdrawn chicks Because the highest concentration of Y_{nb} occurred when the cytoplasmic receptor concentration was lowest, it seems plausible that the non-binding form represents a recycling pool of receptor. It is also conceivable that Y_{nb} represents the first stage of irreversible receptor degradation. We do not favour the latter explanation for the following reasons: (1) the conversion of the non-binding to the oestrogen-binding form is possible simply by increasing the concentration of Mg^{2+} and specific nucleotides in the cytosol; (2) sucrose gradient analysis indicates that the receptor obtained by conversion from Y_{nb} has similar physical properties to the endogenous steroid-binding form; (3) although soluble receptor concentrations vary according to the time after withdrawal from diethylstilboestrol, the concentration of receptors after treatment with ATP/Mg^{2+} shows much less variation—after withdrawal from diethylstilboestrol, the concentration of Y_{nb} is inversely proportional to that of the oestradiol-binding receptors. Collectively, these data indicate that the controlled reversible interconversion between Y and Y_{nb} is associated with physiological receptor recycling. Furthermore, because recovery of Y receptors (which have been reduced *in vivo* or by dialysis treatment *in vitro*) can be accomplished by treatment of Y_{nb} with Mg^{2+} and ATP, the continued presence of ATP and Mg^{2+} may be necessary for maintenance of the steroid-binding characteristics of the Y form of the oestrogen receptor, similar to the mechanism proposed for the glucocorticoid receptor by Munck *et al.*[12]. The precise mechanism of these intriguing observations is currently under investigation.

Oestrogen receptor augmentation in the calf uterus, which contains only one form of active oestrogen receptor, has been shown recently by Migliaccio *et al.*[13] to be associated with a Ca^{2+}-stimulated phosphorylation. Although we agree that a phosphorylation reaction is associated with receptor augmentation, we do not find that Ca^{2+} stimulates this process in our system.

We thank Nita Burke for technical assistance. This work was supported by NIH grant HD17727 and in part by Robert A Welch Foundation grant AU844.

Table 2 Reversibility of the conversion of oestrogen receptor Y to its non-oestradiol binding form

Treatment	Concentration of Y $\times 10^{10}$ M	K_d (nM)
Control	0.81	0.91
Dialysis	Undetectable	0
Dialysis, ATP/Mg^{2+}	0 78	1.0

Binding assays were performed on chick oviduct cytosol and analysed as described in Fig 1. Cytosol was dialysed against two changes of 1,000-fold excess TESH buffer for 24 h at 4 °C using Spectrapor dialysis tubing with a relative molecular mass cutoff of 3,500 ATP and Mg^{2+} were used in the presence of an ATP regenerating system according to the method of Barnett *et al*[11] Assays were incubated at 30 °C for 3 h then at 4 °C for 18 h. In three experiments, cytosol dialysis reduced Y concentration to undetectable levels, addition of ATP/Mg^{2+} resulted in recovery of 97.8±1.1% of Y.

Dihydropyridine receptors in muscle are voltage-dependent but most are not functional calcium channels

Lawrence M. Schwartz*, Edwin W. McCleskey* & Wolfhard Almers

Department of Physiology and Biophysics, University of Washington, Seattle, Washington 98195, USA

1,4-Dihydropyridines are a new class of compounds believed to bind specifically and with high affinity to voltage-dependent calcium channels[1–5]. They may be the first example of a ligand of use in the extraction[1,2] and purification[3] of the Ca channel. Although Ca channels and dihydropyridine receptors are found in many tissues, the richest and most convenient source is skeletal muscle[4]. Functionally, 1,4-dihydropyridines such as nifedipine and nitrendipine block Ca channels[6–11]; this effect is believed to form the basis for their clinical importance as Ca antagonists in relaxing vascular smooth muscle[6]. But where currents through Ca channels can be measured directly[7–10], the block has required 100–1,000 times higher concentrations of dihydropyridine than necessary for the saturation of dihydropyridine binding sites[1,5]. This discrepancy has remained unresolved because the study of pharmacological effects on Ca channels has required intact cells, while it has been difficult to investigate binding in other than cell-free preparations. Here we describe a method for measuring dihydropyridine binding to intact skeletal muscle and we compare our results with voltage-clamp measurements of Ca-channel block. We conclude that less than a few per cent of the binding sites in skeletal muscle represent functional Ca channels, contrary to general belief.

Figure 1*a* shows uptake of the 1,4-dihydropyridine ^{3}H-PN-200/110, a new and potent Ca antagonist[12,13] and close analogue of nitrendipine, by intact frog sartorius muscle While the drug was taken up, its concentration in the medium fell. The drug content of the muscles, calculated from the disappearance of drug from the medium, stabilized within 1-2 h Unfortunately, most of the uptake is an unsaturable distribution of the highly lipophilic drug into the hydrophobic reservoirs of the muscle To test for the presence of any saturable component of uptake, five pairs of frog sartorius muscles were incubated for 6 h in Ringer's solution containing ^{3}H-PN-200/110 at a final concentration of 0.6 nM With each pair, the first muscle was exposed to labelled drug alone and the second exposed also to a saturating concentration (700 nM) of unlabelled nitrendipine. After the muscles were blotted, weighed, digested and assayed for radioactivity, it appeared that nitrendipine reduced the uptake of the label ^{3}H-PN-200/110 by an average of 8.0± 0.8 pmol g^{-1}, indicating that the label and nitrendipine compete for a finite number of sites. However, a large and presumably nonsaturable uptake remained in nitrendipine (13.8 pmol g^{-1}) and made similar measurements at higher drug concentrations prohibitively noisy

To diminish noise, a protocol was developed to measure saturable and nonsaturable components on the same muscle. The experiment in Fig 1*b* is similar to that shown in *a*, but after equilibrium had been reached, a small volume of concentrated nitrendipine in ethanol was added to displace any saturably bound label (arrow). In the following 1-2 h, the muscle released label (1.9 pmol g^{-1}) and the concentration of ^{3}H-PN-200/110 in the medium increased from 1.6 to 2.1 nM (not shown). When ethanol is added without nitrendipine, release of the label is much less or does not occur

The experiment may be used to determine the amount of saturably bound label Before nitrendipine was added, the total uptake (B_t = 63 9 pmol g^{-1} in Fig. 1*b*) had saturable (B_s) and nonsaturable components ($B_{n,b}$), both in equilibrium with 1.6 nM label.

$$B_t = B_s + B_{n,b} \quad (1)$$

Two hours after adding nitrendipine, all label remaining in the muscle, $B_{n,a}$ (62.0 pmol g^{-1} in Fig 1*b*), should be contained in the nonsaturable pool. Subscripts 'b' and 'a' refer to values before and after addition of nitrendipine. $B_{n,a}$ should be larger than $B_{n,b}$ because the muscle is now in equilibrium with a higher concentration of label. If nonsaturable binding increases linearly with concentration, then

$$B_{n,b} = B_{n,a}[\text{label}]_b/[\text{label}]_a \quad (2)$$

In Fig. 1*b*, $B_{n,b} = 62.0 \times 1.6/2.1 = 47.2$ pmol g^{-1}; therefore, from equation (1), $B_s = 63.9 - 47\,2 = 16.7$ pmol g^{-1}. Thus, at 1 6 nM, the muscles in Fig. 1*b* bound 16.7 pmol g^{-1} of label that could be displaced by nitrendipine.

Figure 2*A* (curve *a*) was obtained from experiments similar to Fig. 1*b* and plots the amount of displaced label against the concentration measured just before the addition of nitrendipine. The curve describes one-to-one binding of label to a single class of sites. The parameters providing the best least-squares fit to the data are a dissociation constant (K_d) of 0.93 ± 0 07 nM and a binding capacity at infinite concentration (B_{max}) of 26 pmol g^{-1} (dashed line). Uptake was independent of whether ^{3}H-PN-200/110 was displaced by nitrendipine or by unlabelled PN-200/110 (five muscles). The filled circle was not included in the fit, it was obtained by counting muscles incubated with and without an excess of nitrendipine, as described above Within experimental error, the result agrees with the other data on curve *a*

When muscles were incubated in a potassium-rich solution (membrane potential −15 mV instead of the −88 mV observed in Ringer's), K_D for ^{3}H-PN-200/110 remained unchanged (1.00 ± 0.12 nM), but B_{max} was three times higher (79 pmol g^{-1}): The apparent increase in the number of binding sites cannot result from an increase in intracellular Ca^{2+} concentration

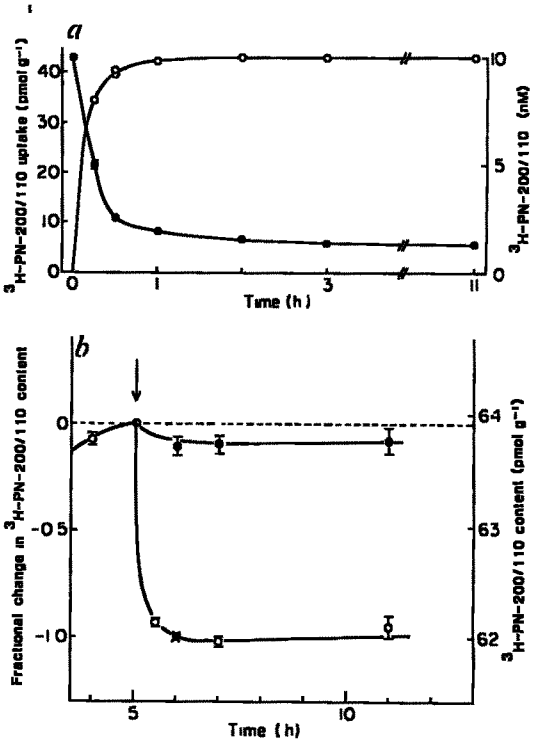

Fig. 1 *a*, Uptake of ^{3}H-PN-200/110 by intact frog sartorius muscles, *b*, release of ^{3}H-PN-200/110 by unlabelled nitrendipine. **Methods.** *a*, Each muscle (weight 40–110 mg) was incubated in a microcentrifuge tube containing 0.35 ml Ringer's solution (115 mM NaCl, 2 5 mM KCl, 1 8 mM $CaCl_2$, 3 mM phosphate buffer, *p*H 7 2), ^{3}H-PN-200/110 at an initial concentration of 10 nM and a 5-mm long magnetic stirrer for gentle agitation. At various times, 0 075-ml aliquots were withdrawn to measure the concentration (●) of label remaining in solution The drug content of each muscle was calculated from the disappearance of drug from the incubate, allowing for the fact that the volume was diminished by each sample. Drug content was normalized to that measured after a 1-h incubation, each point plotted (O) is the mean from five muscles In this experiment, the average uptake after 1 h was 43 ± 2 2 pmol per g wet weight; this defines the left ordinate. When no muscle was present, the concentration of label did not decline with time, indicating that no label was taken up by the microcentrifuge tubes. *b*, Protocol as in *a*, except that the first and second samples were always taken after 4 and 5 h of incubation, respectively After the second sample (arrow), 1 µl ethanol containing either no drug (●) or 1.5 mM nitrendipine (gift of Dr A Scriabine, Miles Institute, O, was added to the incubation tube and additional samples taken at later times. The added nitrendipine is expected to result, at equilibrium, in a concentration of ~700 nM, as the drug dilutes into an average nitrendipine space of 1 8 ml per muscle (30 5 ± 0.9 ml g^{-1}, n = 10, mean muscle weight 60 mg). This concentration is sufficient to displace all bound label, as the same amounts of label were released within 1 h of adding either 2 times smaller or 10-fold larger amounts of nitrendipine (not shown) The left-hand ordinate plots the change in muscle content of ^{3}H-PN-200/110 that occurred after the addition of ethanol and/or nitrendipine Throughout, the change in content was normalized to that at 6 h (O, ⊗). The average change was 1.9 ± 0 1 pmol g^{-1} (n = 20); this value, together with the average content at 5 h (63.9 pmol g^{-1} in this group of muscles), defines the right-hand ordinate ●, Not normalized Temperature, 22–24 °C throughout, ^{3}H-PN-200/110 (NEN, specific activity 85 Ci mmol^{-1}) was the optically pure (+) stereoisomer Vertical error bars indicate s e m and are omitted if smaller than the size of the symbol.

caused by release from the sarcoplasmic reticulum or, possibly, by failure of the Na/Ca exchange in the absence of external Na. First, incubation began long after the K-contracture accompanying the depolarization had subsided Second, the absence of Ca^{2+} inside and out had no effect on uptake (Table 1, experiment 1), confirming previous results on cell-free preparations[1] Apparently, depolarization acts like the drug diltiazem,

which, in cell-free[13] or even solubilized skeletal muscle preparations[2], also increases the number of nitrendipine or PN 200/110 binding sites without changing their affinity. The diltiazem result indicates that dihydropyridine receptors may exist in a form which does not bind antagonist dihydropyridines, or in which their affinity for them is too low to be detected by the usual assays. Diltiazem is thought to convert low- into high-affinity receptors; we suggest that depolarizarion has the same effect.

Figure 2*B* shows that the nonsaturable uptake depends linearly on concentration, as expected. Results in Ringer's and in high-K solution are identical. The regression line drawn through the data points corresponds to a PN-200/110 space of 27.5 ml per g wet weight.

The value for K_D obtained here agrees well with results from cell-free skeletal muscle preparations (for PN-200/110, K_D = 1.4 nM in guinea pigs[13]; for nitrendipine, K_D = 1.7 nM in rabbits[1]), as does the value for B_{max}. Because intact frog muscles have a protein content of 153 ± 10 mg per g wet weight (Lowry method, five muscles), B_{max} in depolarized muscle is 0.5 pmol per mg protein; in homogenized (and therefore depolarized) rabbit muscle, B_{max} = 0.8 pmol g^{-1} (ref. 1). This agreement supports the validity of our assay for dihydropyridine binding in intact muscle.

Table 1 shows that adrenaline (0.01 mM) causes no significant change in PN-200/110 binding (expt 2), even though the hormone increases current through Ca channels in cardiac muscle[14]. Muscles bound less ^{3}H-nitrendipine than ^{3}H-PN-200/110 (ref. 13), but the preference for PN-200/110 is apparently less marked in depolarized fibres (expts 3, 4).

Table 1 Uptake of dihydropyridines by frog sartorius muscles

Expt	Control	Test	Test/control
1	High K	Ca-free	1.15 ± 0.06
2	Ringer's	Adrenaline, 10 μM	0.91 ± 0.17
3	Ringer's	^{3}H-nitrendipine	0 22 ± 0.03
4	High K	^{3}H-nitrendipine	0.37 ± 0 02

Throughout, control and test conditions were compared on paired muscles (five muscle pairs per experiment) and specific uptake was measured as described in Fig 2 legend. Control: Incubation at final concentrations of 1.5-1 6 nM ^{3}H-PN-200/110 (Ringer's) or of 2.4-3 4 nM-(high-K solution; composition as in Fig. 2). Expt 1, the incubation fluid was Ca-free (40 mM tetraethylammonium (TEA^+)-EGTA, 65 mM TEA^+-aspartate, 5 mM TEA^+-MOPS, *p*H 7.0) and the muscles were chopped into 1-mm pieces to keep them depolarized and to allow this solution to enter the cytoplasm. Expt 2, as the control, but with 10 μM adrenaline added to the incubation fluid Expts 3, 4, as the control, but ^{3}H-nitrendipine (NEN) was used as label instead of ^{3}H-PN-200/110 The final concentrations of ^{3}H-nitrendipine (1.49 ± 0.06 nM in expt 3, and 3.37 ± 0.23 nM in expt 4) were larger than those of ^{3}H-PN-200/110, therefore, the uptake of ^{3}H-PN-200/110 was corrected (using K_D = 1.0 nM) to apply to the final concentrations obtained with ^{3}H-nitrendipine.

It is of interest to consider the number of binding sites observed here. With 80 pmol g^{-1}, there are four times more dihydropyridine sites than there are Na channels[15]; with a transverse tubule membrane area of 2,200 cm^2 per m of fibre volume[16], there are ~230 sites per μm^2 of that membrane. 80 pmol g^{-1} correspond to ~5×10^{13} sites per ml fibre volume, each representing a protein complex of relative molecular mass ~210,000 (ref. 17). This number of sites is large compared with the observed Ca current. At ~−20 mV, where Ca current is largest (Fig. 3*a*), its average value is 102 ± 9 mA ml^{-1} (n = 6). This corresponds to 2 fA per site, much less than the current through single Ca channels observed at similar potentials and external Ca^{2+} concentration (~0.1 pA in chromaffin cells[18] or 0.07 pA in cardiac myocytes[19]). Evidently, there are 35 to 50 times more dihydropyridine binding sites than there are voltage-dependent Ca channels that can be activated to pass current. This difficulty is not removed by considering that, at the normal negative resting potential, most dihydropyridine receptors have an undetectably low or no affinity for PN-200/110. Even recep-

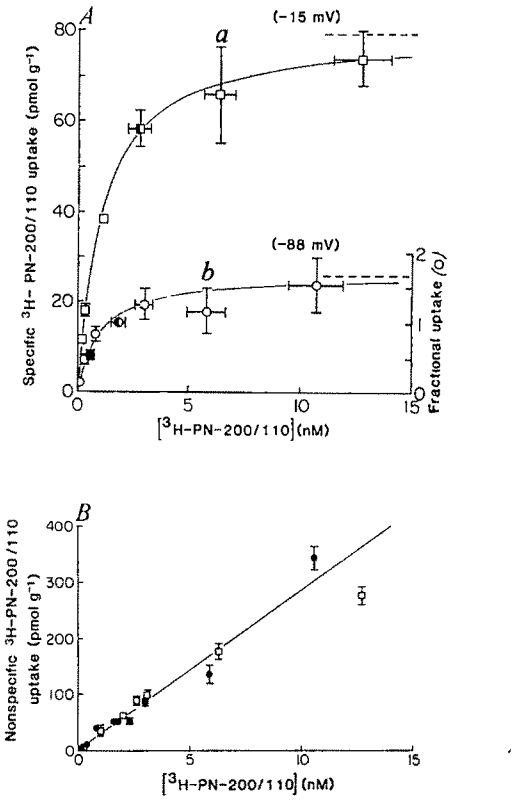

Fig. 2 *A*, Saturable uptake of ^{3}H-PN-200/110 determined from the drug contents and concentrations before and 2 h after adding an excess of unlabelled nitrendipine (see Fig. 1*b* and text) *B*, Non-saturable uptake against concentration in Ringer's (filled symbols) and high-K solution (squares).

Methods. Paired sartorius muscles were used; the first was incubated at an approximately fixed final reference concentration (1.9 nM in curve *a*; 2.7 nM in *b*), the second at various test concentrations. Specific uptakes (calculated from the displacement of label by nitrendipine) at the test concentrations were normalized to that at the reference concentration (the ordinate on the right of curve *a* is included as an example). Each data point represents measurements from at least five muscles; s.e.m. (uptakes) or s.d. (final concentrations) are indicated. Curve *a*, in Ringer's solution as in Fig. 1*b*, curve *b*, in a high-K solution with the same Ca^{2+} activity as Ringer's solution (40 mM K_2SO_4, 5 mM $CaSO_4$, 2 mM Tris-maleate, 113 M sucrose, *p*H 7.2). On first contact with the K-rich solution, muscles went through a transient contraction, during which time they were kept pinned out in a dish to prevent shortening. We rejected measurements from muscles that showed signs of contracture at the end of the experiment. To measure the membrane potentials in Ringer's, a muscle was incubated for 5 h and transferred to a dry recording chamber, then the incubate was poured over it. The average resting potential in this muscle was 87 5 ± 0.6 mV (n = 15). The membrane potential in the high-K solution is ~−15 mV. Curves *a* and *b* are least-squares fits of the function $B_s = B_{max} \times [label]/([label] + K_d)$. For least-squares fitting, uptakes and final concentrations were entered into the computer for each muscle, for the uptake, the ratio of test/reference was entered for the test muscle and a value of 1.0 for the reference muscle. Values for B_{max} giving the best least-squares fit (dashed lines) were 1.71 ± 0.04 times (Ringer's) or 1.35 ± 0.04 times (high-K solution) the reference uptake. Half-filled symbols represent uptakes (in pmol g^{-1}) at the reference concentrations; their values were 15 4 ± 0.7 pmol g^{-1} (n = 33) in Ringer's and 58 7 ± 3.8 pmol g^{-1} (n = 25) in the high-K solution These values define the ordinate on the left. At low concentrations, saturable and nonsaturable uptakes can be obtained more directly by comparing paired sartorius muscles incubated for 5 h in high-K solution One muscle was incubated without, and the contralateral muscle with, excess (700 nM) nitrendipine. Digesting the muscles and then counting radioactivity showed that, at 0.71-nM label, the uptake with nitrendipine was 24 4 ± 0.5 pmol g^{-1} less than that without (five muscle pairs). A group of five muscles from the same batch of frogs and processed as described in Fig. 1*b* took up 26.5 ± 4.1 pmol g^{-1} at 0.77 nM label, an identical result

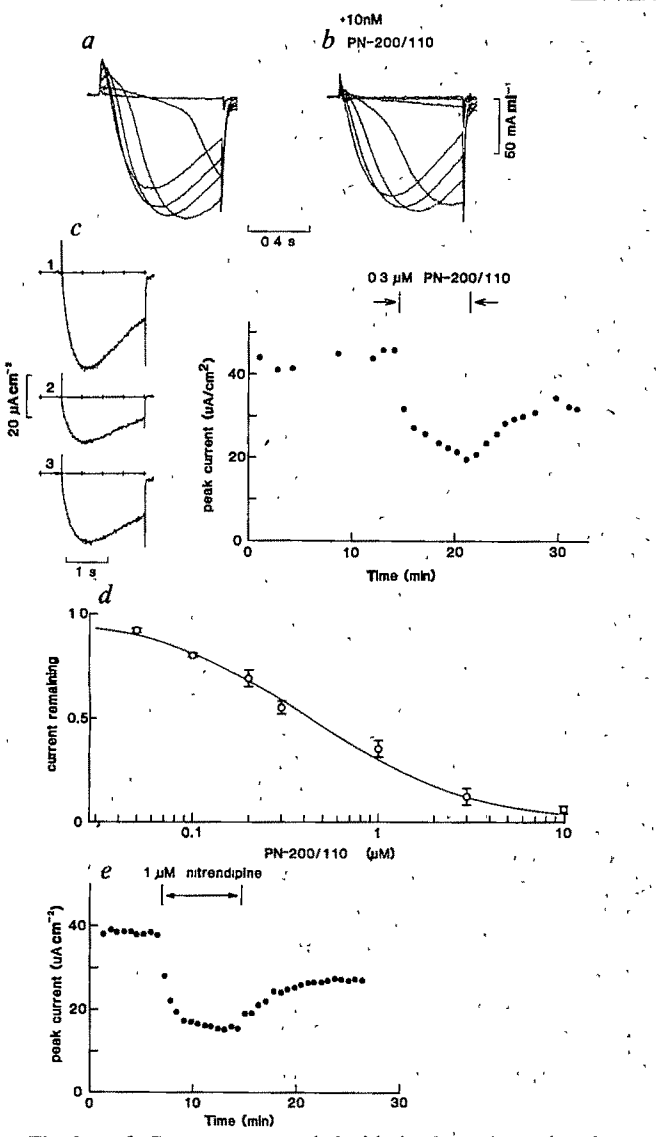

Fig. 3 *a*, *b*, Ca currents recorded with the three-electrode voltage clamp[22] from frog sartorius muscle fibres in a solution containing 107 mM TEA-methylsulphonate, 10 mM Ca-(methylsulphonate)$_2$, 10 mM MOPS buffer (*p*H 7.2) and 1 μM tetrodotoxin. ^{3}H-PN-200/110 binding in this solution was 1.40±0.22 times that in Ringer's solution (five muscle pairs). 350 mM sucrose was added to abolish contraction. Holding potential −90 mV; current traces were recorded during steps to between −60 or −50 mV and 0 mV in 10-mV increments. Ordinate calibration: At 23 °C in isotonic solution, the myoplasmic resistivity is calculated to be 150 Ω cm (ref. 23); adding 350 mM sucrose at that temperature increased the myoplasmic resistance per unit length 1.49±0.13-fold (n=7; microelectrode cable analysis). Consequently we used a myoplasmic resistivity of 223 Ω cm in equation (4) of ref. 22 to refer currents to the fibre volume in isotonic conditions. *a*, Control; *b*, from the contralateral muscle of the same animal after 6 h incubation in Ringer's +10 nM PN-200/110. The drug was retained continuously also after the incubation and during the recording period. *c*, Left, Ca-current during step depolarizations from the holding potential (−80 mV) to 10 mV before (1), during (2) and after (3) the presence of 300 nM PN-200/110. Right, peak current as a function of time, referred to the surface of a cylinder of the same length and diameter as the piece of fibre from which current was collected. External solution as in *a*, *b* except that sucrose was omitted. Vaseline-gap voltage clamp[7] with fibre ends cut in the solution of Table 1, expt 1. Throughout (*a*–*c*), currents were corrected for leakage and capacitive currents[7]. *d*, Peak current remaining 4–5 min after drug application as a fraction of that recorded immediately before; each point represents data from 3–8 experiments as in *c*. PN-200/110 (a gift of Dr C. E. Eden, Sandoz) was a 1/1 mixture of (+) and (−) stereoisomers. Their individual potencies are not known[12] but in the worst case one isomer would be inactive and the concentrations for the active isomer would be half those indicated. *e*, As *c*, but with nitrendipine.

tors in the low-affinity form are so abundant (79−26 = 53 pmol g^{-1} in Fig. 2) that at most a few per cent of them can represent functional Ca channels.

Figure 3*b* demonstrates that PN-200/110 has no or only small effects on Ca currents at concentrations high enough to load nearly all high-affinity sites. Although this muscle had been exposed continuously to 10 nM PN-200/110 for the previous 6 h, it retained Ca currents that were as large, or almost as large (87±5 mA ml^{-1}, n=7), as in the untreated contralateral muscle from the same animal (102 mA ml^{-1}). The slightly smaller average value with drug may result from the longer time that elapsed between dissection and recording (9–11 h). Hence, the drug can bind without blocking Ca channels, as has been suggested for synaptosomes[20].

At higher concentrations, PN-200/110 causes block, as do other 1,4-dihydropyridines. In Fig. 3*c*, 300 nM drug diminished Ca current to ~47% within 6 min, with partial recovery of current after drug removal. Other, similar experiments yielded the dose-response curve in Fig. 3*d*. The curve describes block by one-to-one binding of PN-200/110 to Ca channels (K_d ~430 nM). Prolonged application does not cause much stronger block. In other experiments (not shown), a semitendinosus muscle was incubated in 300 nM PN-200/110 for 5 h; then, with the drug still present, three single fibres were dissected over the next 4 h and currents recorded. Peak currents averaged 27±5 μA per cm^2 of fibre surface membrane. Four fibres from the drug-free contralateral muscle had previously given 58± 9 μA cm^{-2}. The difference is roughly consistent with Fig. 3*d*. Figure 3*e* shows block of Ca current by nitrendipine; this and two other such experiments suggest that ~700 nM of the drug is required to block half the channels.

Thus, PN-200/110 can bind without causing block, and there are many more high- (and low-) affinity binding sites than there are Ca channels. Both findings are explained most easily if most binding sites for antagonist 1,4-dihydropyridines are not functional Ca channels. In skeletal muscle, they may be unrelated to Ca channels, but this view is contrary to the circumstantial evidence in smooth and cardiac muscle and in phaeochromocytoma cells[21]. An alternative speculation is that dihydropyridine receptors represent a large reserve of dormant Ca channels kept for an unknown physiological emergency.

The voltage dependence of dihydropyridine binding described here may be compared with models proposed for cardiac muscle[11], where low- and high-affinity binding sites are thought to represent normal and inactivated Ca channels, respectively, that are in voltage-dependent equilibrium. In such a model, Ca channels should bind drug with a single apparent K_d (given in ref. 11) that diminishes in a graded fashion as the membrane potential is made more positive and the fraction of inactivated channels increases. The prediction is a competitive inhibition of drug binding by negative potentials, with a change of K_d but not of B_{max}. Figure 2 shows the opposite. In skeletal muscle, negative potentials evidently inhibit binding in a non-competitive fashion.

We thank Laura Bolles for technical help, Dr B. M. Curtis for suggesting the use of PN-200/110, Dr W. A. Catterall for helpful discussions and Drs E. Neher and W. Stuhmer for comments on the manuscript. L.M.S. held a postdoctoral fellowship of the American Heart Association. This work was supported by DHHS grant AM17803.

Central nervous system and peripheral nerve growth factor provide trophic support critical to mature sensory neuronal survival

Eugene M. Johnson Jr & Henry K. Yip

Department of Pharmacology, Washington University School of Medicine, 660 South Euclid Avenue, St Louis, Missouri 63110, USA

Primary sensory neurones in cranial and dorsal root ganglia (DRG) of adult animals are generally thought to be maintained through connections with their peripheral (but not central) targets by trophic factor(s) other than nerve growth factor (NGF)[1]. Damage to the peripheral process of sensory neurones results in a dramatic response or even death of the neurones, whereas axotomy (cutting) of the central process does not initiate profound reaction in these neurones. The development and maintenance of neurones are highly dependent on a supply of trophic agents produced by targets and retrogradely transported via the peripheral process to the cell body[2]. NGF deprivation in fetal rodents produced either by exogenously administered antibodies or by those of maternal origin, results in death of DRG[2-5] and of some cranial sensory neurones[6]. However, as chronic NGF deprivation in neonatal or adult rodents produces little or no cell death[7-10], it has been assumed that some other trophic factor(s) derived from the peripheral target sustains sensory neurones in postnatal life. By inducing NGF deprivation by autoimmunizing guinea pigs with mouse NGF and/or by cutting the central root (process) of a DRG, we demonstrate here that under certain conditions DRG neurones require NGF and centrally derived trophic support. Our results indicate that sensory neurones are maintained by the trophic support provided by both peripheral and central targets. This support is mediated by NGF and other as yet unidentified trophic factors. The relative importance of the two target fields and NGF compared with other trophic factors changes during development.

Chronic peripheral NGF deprivation was produced in young adult Hartley guinea pigs (Charles River) by immunizing with 2.5S NGF as described previously[4,8]. Age-matched control animals were not immunized. Two months after the immunization of the experimental group, surgical lesions to the central and/or peripheral processes of sensory neurones were performed as described in Fig. 1 legend. Three months after surgery, the effect of the single or combined lesions on neuronal number in L_6 DRG of nonimmunized control guinea pigs is shown in Table 1. Sciatic nerve crush injury results in a loss of ~20% of L_6 DRG neurones. As 80-85% of L_6 DRG neurones project down the sciatic nerve[8], 25% of the axotomized neurones die. In contrast, cutting of the dorsal root does not result in any cell loss, consistent with many reports and the data of Hinsey *et al.*[11], who found no decrease in neuronal number of S_2 lumbar ganglion in adult cat after dorsal root section. The data in Table 1 also show that combined lesions of the central and peripheral processes do not result in a statistically significant additional cell death, consistent with the observations of Hare and Hinsey[12] who observed that lesion of the central process did not increase the severity of the neuronal response to crushing of the sciatic nerve in cats killed 6-35 days after surgery.

The consensus that the central process has little or no role in providing trophic support of the sensory neurone clearly is not the case in immature animals. We have shown[13] in newborn rats that a loss of 50% of L_5 DRG neurones is produced by either a central or a peripheral lesion and that the combined lesion results in the loss of 70% of the neurones. Cell loss produced by either the single or combined lesion can be prevented by concomitant treatment with systemic NGF. Also, ^{125}I-labelled NGF can be efficiently and specifically retrogradely transported from the spinal cord to the DRG[13,14]. These experiments[13] demonstrate that the central process, as well as the peripheral process, has a critical role in providing trophic support to the developing sensory neurones in newborn rats and suggest that the trophic molecule provided by the central process is NGF.

Peripheral NGF deprivation by chronic exposure to anti-NGF in adults does not produce DRG neuronal death nor does it increase neuronal death in peripheral nerve crush[8]. It is clear, however, that even in adults, NGF deprivation has an adverse effect on DRG neurones. Chronic NGF deprivation in adults results in decreased levels of substance P[7] and a modest atrophy of neurones in DRG[8]. Thus, in contrast to the dependence of immature sensory neurones on peripheral NGF for survival, the mature neurone atrophies but does not die as a result of peripheral NGF deprivation. Similarly, the loss of trophic support from the central process results in cell death of immature DRG neurones; however, this loss of trophic support in adults is insufficient to cause cell death. We speculate that the conclusion that mature DRG neurones do not require NGF for survival may be incorrect because it ignores the possibility that

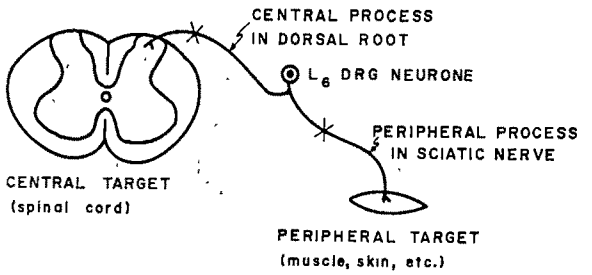

Fig. 1 Anatomy of the L_6 spinal sensory neurone showing the terminal areas of its central (spinal cord) and peripheral processes (for example, muscle). Crosses indicate lesion sites. Two months after immunization of the experimental group, animals were anaesthetized with chloral hydrate (350 mg per kg). Animals receiving a central lesion underwent an L_6 dorsal rhizotomy following exposure by a thoraco-lumbar laminectomy. The L_6 central process was sectioned near its entry to the spinal cord. Animals receiving a peripheral lesion underwent axotomy of their sciatic nerves. The nerve was exposed in midthigh and crushed for 40 s with a pair of jeweller's forceps at the tendon of the *obturator internus*. Animals were prepared with either a central or peripheral lesion alone or a combination of the lesions. Corresponding sham-operated control animals were prepared. Immunized animals were boosted with NGF monthly to maintain their titre of anti-NGF, and 90-100 days after lesion, they were perfused transcardially with saline and then with 10% formol saline. The sixth lumbar ganglia were removed bilaterally and immersed in 10% formalin and subsequently embedded in paraffin using standard histological techniques; 8-μm serial sections of the ganglia were stained with toluidine blue. The slides were coded so that their identity was unknown to the examiner. In every tenth section, neurones with a nucleolus were counted and the raw counts corrected[17].

Table 1 Neuronal numbers in L_6 DRG after lesioning of the central and/or peripheral processes in normal guinea pigs

Group	Lesion		Cell no. in L_6 DRG	% Control
	Central	Peripheral		
A	−	−	17,897 ± 711 (9)	100
B	+	−	17,439 ± 695 (4)	97
C	−	+	14,304 ± 1,184 (5)	79*
D	+	+	12,777 ± 847 (3)	71*

The data were analysed using two-way analysis of variance including Satterwaithe's correction of degrees of freedom resulting from unequal group size[16].

* Statistically different from control (group A); $P < 0.02$.

Table 2 Neuronal number in the L_6 DRG after lesioning of the central and/or peripheral processes in NGF-immunized guinea pigs

Group	Lesion Central	Lesion Peripheral	Cell no. in L_6 DRG	% Control
A	−	−	18,113±815 (7)	100*
B	+	−	13,589±996 (3)	75
C	−	+	14,695±726 (3)	81
D	+	+	10,641±711 (4)	59*

* Statistically different from all other groups (maximum $P < 0.054$)

NGF may be taken up by central terminals in the spinal cord and retrogradely transported by the central process to the DRG. Antibodies to NGF presumably would not cross the blood-brain barrier and would not prevent access of the DRG neurone to central nervous system (CNS)-derived NGF (or other trophic factor)

The data in Table 2 show the effects on sensory neurones of lesioning either the central or peripheral process or both in a group of animals chronically deprived of NGF. The peripheral lesion alone results in ~20% loss of DRG neurones[8]. However, in the NGF-deprived animal, cutting only the central process resulted in a 25% loss. In anti-NGF-producing animals subjected to a peripheral crush and a central lesion, a further neuronal loss of 27% (14,695-10,641) is observed. Thus, when the trophic support of peripherally derived NGF is removed, at least some populations of sensory neurones become dependent on centrally derived trophic support for survival. Conversely, when deprived of trophic support through the central process, at least a proportion of sensory neurones requires peripheral NGF for survival.

These results suggest that survival of sensory neurones in the adult animal depends on trophic support from both the central and peripheral targets. As peripheral NGF deprivation produces atrophy but not cell death of DRG neurones, whereas crushing the nerve does produce (~25%) cell death, we suggest that NGF is but one of possibly several peripherally provided molecules that trophically support DRG neurones. As NGF deprivation plus central lesion produces an amount of cell death comparable with that caused by peripheral crush lesion, the total trophic support provided by the central process is equivalent to the non-NGF component of peripheral trophic support. Thus, the loss of any one of these three trophic components (peripheral NGF, peripheral non-NGF, centrally derived factor) produces atrophy but not death. Removal of any two of these components results in loss of ~20% of cells. Loss of all three components would therefore be expected to result in the death of even more cells (Table 2). The data in Table 1 suggest that central process lesion may increase the severity of a peripheral crush in control animals, but the decrease in neuronal number is not statistically significant. Thus, we propose that the trophic support of a DRG neurone in the adult animal is represented by the sum of the trophic effects of NGF and other unknown factors derived from the periphery and a factor or factors derived from the CNS, one of which may be NGF. Based on our limited data, we cannot provide a complete explanation of this hypothesis. Interpretation is complicated by the fact that the DRG is composed of heterogeneous cell types. We do not know, for example, whether the 20% of cells that die after peripheral lesion are the same cells that die after peripheral NGF deprivation combined with a central lesion. In addition, the experiment used a peripheral crush lesion rather than a cut; thus, regeneration of the distal processes was possible and probably rather efficient[8]. Greater cell loss would be expected if the sciatic nerve were cut rather than crushed. Similarly, 15-20% of neurones in L_6 DRG do not project down the sciatic nerve and some neurones may reach the CNS via the ventral root, rather than the dorsal root[15].

Irrespective of the complications in providing a precise accounting of the cell death, the fact that trophic support for sensory neurones is provided via their central processes seems to explain the apparent lack of dependency of mature sensory neurones on NGF for survival, deduced by experiments using anti-NGF. The data suggest that survival of sensory neurones is dependent on relative trophic support provided by both the central and peripheral processes, although the quantitative support by the peripheral process is overall more important in adult animals. Because in newborn rats cell losses after lesioning of the central or peripheral process are the same[13], the results indicate that the relative importance of the trophic support provided by the central and peripheral processes changes as a function of age.

FOUR DYNAMITE REASONS WHY YOU SHOULD SUBSCRIBE TO BIO/TECHNOLOGY NOW . . .

1 **You'll save time.** Because you don't have time to read every journal in the field, BIO/TECHNOLOGY is written and edited to give you all the information you need in ONE convenient source. BIO/TECHNOLOGY is the only journal to give you news. Features. Original research. Product evaluations. Industrial applications. Job openings. Book and product reviews. And more. If it's important to your work, you'll find it between the covers of BIO/TECHNOLOGY.

2 **You'll learn new ways to improve your on-the-job skills and run a more successful operation.** Each month BIO/TECHNOLOGY gives you the scoop on invaluable start-up information . . . the latest instrumentation . . . marketing breakthroughs . . . funding sources . . . new technologies . . . patents and licences . . . profiles on how others are avoiding the pitfalls and reaping the rewards. In fact, just one practical tip from BIO/TECHNOLOGY can be worth many times the cost of your subscription.

3 **You'll be up-to-date on all major industry developments.** With correspondents all over the world, BIO/TECHNOLOGY delivers the inside story on who's doing what, where. You'll get the latest word on changing government regulations and tax law, and how they affect your work.

Plus you'll read original research papers by bench scientists, engineers, and biologists that will help keep you in the forefront of every new discovery worth knowing about.

4 **You'll get new ideas you can put to use immediately.** BIO/TECHNOLOGY lets you rub elbows with eminent scientists, tour new facilities and learn how new processes work in every field from genetic engineering to molecular biology. Each month, BIO/TECHNOLOGY helps spark ideas for your own research, for new industrial applications and for getting along in the increasingly competitive financial arena.

If you're not already subscribing to BIO/TECHNOLOGY, don't delay the moment any longer - return the coupon below and we will send you twelve issues. You risk nothing. If for any reason BIO/TECHNOLOGY doesn't live up to your highest expectations; just let us know and you'll receive a full refund on all unmailed copies Remember too, that your subscription may be tax deductible

TO START RECEIVING YOUR SUBSCRIPTION, FILL OUT THE COUPON BELOW AND RETURN WITH PAYMENT TO:

Greek archaeomagnitudes

RELIABLE determination of the ancient geomagnetic field intensity is difficult; any new approach, such as that of Walton[1], is to be welcomed. Although the method is new and complex, it does not follow that it necessarily gives reliable answers, particularly as its validity rests on various theoretical assumptions about the behaviour of the magnetic carriers. We consider that Walton's dismissal of the linearity test in the commonly used Thellier technique is premature and insecurely founded. Certainly, this technique always needs to be carried out meticulously, as emphasized by Thellier, otherwise erroneous results are obtained that can, if taken at face value, lead to the supposition of rather exotic behaviour by the geomagnetic intensity in the past. Hence, Walton's finding that his earlier determinations using the Thellier technique were unreliable does not mean that all Thellier results are suspect.

In any linearity test the critical question is 'How linear is linear?' and in the examples referred to by Walton, it may well be that the criteria used were not sufficiently strict. On the other hand, we have confirmed the effectiveness of reliability criteria, where they are stringently applied, by re-examining our recent Thellier results[2] for the second millennium BC; we have remeasured several of our samples using the coercivity monitoring technique developed by Shaw[3] and find that the agreement is good. In this method, the coercivity spectrum of the natural remanent magnetization (NRM, the ancient magnetization) is compared with that of the thermoremanent magnetization (TRM, the magnetization acquired on cooling after the laboratory heating); changes in shape indicate that the laboratory heating has caused mineral alteration and there is risk of error. Also, the coercivity spectrum of an acquired remanent magnetization (ARM, magnetization acquired from a weak steady field in the presence of a strong alternating field) given before heating is compared with that of an ARM given after heating; as well as spectrum shape, this monitors any increase or decrease in the magnetic carriers in each coercivity interval, thus providing a built-in quantitative measure of the magnetic alteration. In the basic Shaw technique the ancient intensity is obtained from the NRM/TRM ratio evaluated from coercivity intervals for which there is no change in ARM strength. In later developments[4,5] it has been shown that, even if alteration occurs, the ARM ratio can be used to correct the NRM/TRM ratio, at least for coercivity intervals >100 mT.

We have now used the Shaw technique, or one of its variants, on eleven samples from several of the sites in ref. 2 (see Table 1). There is agreement with the Thellier values to within 15% for nine of the samples; seven of these are within 10% with the Shaw values on average 5% lower than the Thellier values. The two remaining samples gave inconsistent results for different coercivity intervals, although always within ±25% of the Thellier value. These are our first results using the Shaw technique and, because there is scope for improvement in our facilities, we consider that good confirmation of the validity of the Thellier results has been obtained. Also, we have used the ARM technique on subsidiary cores (19 samples), with intervening heatings to various of the temperature steps used in the Thellier determination. In this way we can determine whether or not alteration has set in by the upper temperature limit of accepted Thellier data; in no case has the ARM change at that limit been >6%. These tests justify our confidence in the results of ref. 2.

Finally, regarding the alteration test of comparison between two measurements made in zero field, suggested by Walton for the Thellier method, we note that his procedure monitors only those carriers having blocking temperatures greater than the magnetization temperature; on the other hand, the in-field measurement is also affected by carriers having lower blocking temperatures. Our experience of comparing demagnetization curves before and after heating indicates that alteration can occur in some blocking temperature ranges without affecting others. A much better test is to compare two in-field measurements, but tests of this type can never give conclusive proof that alteration has not occurred because of the probability that it occurs rapidly and is effectively complete during the first stage of a given temperature step. These comments apply equally to the Walton method.

Table 1 Comparison of Shaw and Thellier techniques

Presumed date BC	Sample location	Intensity ratio (Thellier)	Ancient intensity (μT) Thellier	Shaw
1550–1500	Apheq, Israel	1.06	45	43
1550–1500	Apheq, Israel	1.15	49	48
1504–1492	Karnak, Egypt	1.17	45	40
1250–1150	Karnak, Egypt	1 51	58	57
1250–1150	Karnak, Egypt	1 53	59	57
1150–1075	Kition, Cyprus	1 62	72	71
1100–950	Karnak, Egypt	1.52	59	51
1100–950	Karnak, Egypt	1.52	59	61
1050–1000	Koukhia, Cyprus	1.53	68	68

The Thellier results are from ref. 2; the intensity ratio quoted is F_A/F_D, where F_A is the ancient intensity and F_D is the intensity at the site attributable to an axial centred geomagnetic dipole of present-day strength (8×10^{22} A m^2)

WALTON REPLIES—There is quite a clear disagreement between recent results for Greece[1] and those of Aitken *et al.*[2].

I have published two sets of archaeomagnetic intensity measurements for Greece. The original data[3] also show the increase in intensity that Aitken *et al.* are proposing to use for archaeomagnetic dating. Unfortunately, the old data in ref. 3 are wrong, which prompted the study in ref. 1. This later study showed that the error was caused by mineral alteration at the higher measurement temperatures. A few samples that showed no evidence of alteration did not show an increase in intensity. It was possible to correct for a small degree of alteration; if the effects of alteration were retained, the increase in intensity referred to above was present in the high temperature points but not at low temperatures. On correction, all the points at all temperatures were consistent, within the experimental accuracy, and the increase disappeared.

The experiments reported in ref. 3 used a technique that did not differ substantially from that used by Aitken *et al.*[2], but Aitken *et al.*[2] express reservations about the technique used in ref. 1. It is important, however, to recognize that in all three methods the ancient intensity is obtained by the same method, thermal demagnetization and magnetization, differing only in the test used for alteration.

More specifically, the method used by Aitken *et al.*[2], and initially by myself,

method 1, compares the moment lost after demagnetizing for a fixed time at a given temperature, with the moment gained in a known field after holding for the same time at the same temperature. My new method, method 2 (see ref 1), also compares the moment lost in zero field on holding the sample for a fixed time at a temperature with the moment gained in the same time period in the laboratory field. In method 2, because the moment of the sample is being monitored continuously, several readings can be made while the sample is hot and, to improve the statistical accuracy, the slope of the best straight line through the points is used instead of simply taking the difference between the first and last reading Thus, the 'theoretical assumptions' on which our methods depend are, up to this point, identical.

The two methods do differ in the means they use to detect alteration, as discussed in refs 1,2. The important point is that alteration was detected using method 2, but was not detected using the linearity test of ref. 2

In the event that alteration is complete by the end of the first heating in method 2, it would still be detected as a sudden change in the value of the ancient intensity at that temperature. Method 2, in other words, also incorporates a 'linearity test'

In any case, the point is not that alteration has been missed but that it has been detected. Almost all the material between 1200 and 300 BC showed evidence of alteration at temperatures below 350 °C. If the altered points were used, high values were obtained for the ancient field in good agreement with refs 2 and 3 If points with no evidence of alteration were used, the increase that Aitken *et al* report, forming the basis for their dating method, disappears.

It will be useful to compare these results with those obtained using the Shaw method. At present Aitken *et al.* report nine values. Of these, three are dated 1500 BC where there is no disagreement. In assessing the remaining six it is important to consider their internal consistency. results between 1250 and 950 BC are between 58 and 72 μT with the Thellier and 51 and 71 μT with the Shaw method. In the same period, nine lie between 46 and 54 μT With so few results the difference is hardly significant

A Grenville Sm/Nd age for the Glenelg eclogite

SANDERS *et al*[1] present data indicating that eclogites within the eastern Lewisian inlier at Glenelg equilibrated at ~1,100 Myr BP at temperatures and pressures of ~700 °C and >12 kbar. On the basis that the overlying Moine cover shows no sign of having exceeded conditions for the lower amphibolite facies, they conclude that the Moine was deposited unconformably on a deeply eroded Lewisian basement following Grenville age metamorphism, a view at variance with much recent work which regards the Moine as a series of late mid-Proterozoic metasediments that underwent widespread metamorphism and deformation at ~1,100–1,000 Myr BP[2–5] Whilst the data produced by Sanders *et al*[1] is not in dispute, their conclusions relating to the conditions of metamorphism of the eclogites and thus the age of sedimentation of the Moine may be questioned.

We consider the suggestion of Sanders *et al.*[1] that the eclogites were metamorphosed at pressures of >12 kbar questionable on four counts. (1) Mineral parageneses and tabulated phase chemistries are not those of an eclogite in the strict sense but of a medium- or high-pressure granulite. Consequently, deriving a pressure by analogy with Green and Ringwood's[6] eclogite field is inadvisable. More realistic pressures of as low as 6 or 7 kbar could be derived from their granulite field. (2) Although Sanders[7] implies that he has corroborative evidence from the garnet/plagioclase/kyanite/quartz geobarometer, this is as yet unpublished and, in view of the problems inherent in modelling plagioclase and garnet activities, may not be conclusive. (3) We have examined staurolite/garnet/kyanite/biotite/quartz-bearing gneisses from the eastern Lewisian in which, on textural criteria, we are confident that all coexisting phases are of Grenville rather than Caledonian age. At temperatures of 650–700 °C, staurolite and quartz will not be stable at pressures in excess of 8 kbar[8,9]. (4) It has been repeatedly shown that garnet-pyroxenite assemblages comparable to those described from Glenelg are stable at relatively low pressures in rocks undergoing dry metamorphism at amphibolite facies conditions[10–12] These pressures could well be consistent with both the pressure stability limits of staurolite and quartz and pressure estimates of 6–8 kbar obtained from mineral assemblages coeval with the early pre-Caledonian metamorphism within the Morar division Moine (D. Barr, personal communication), in which case there may be no significant difference between the metamorphic conditions of the Eastern Lewisian and those of the Moine

In this light a more reasonable explanation is that the ~1,100 Myr BP age[1] dates both the equilibration of the eclogites and the initial amphibolite facies metamorphism of the Moine. Isotope data considered to relate directly to the age of initial metamorphism of the Moine includes Rb/Sr whole-rock ages of ~1,100–1,000 Myr BP on the Morar and Lochailort pelites and the Ardgour gneiss[13–15], which are interpreted by Sanders *et al.*[1] as dating sedimentation and diagenesis rather than metamorphism Whilst the interpretation of the isotope data relating to the metasediments is equivocal[16], we note that the Ardgour gneiss is now generally regarded as a member of an extensive suite of deformed granitic intrusions where emplacement was coeval with amphibolite-facies metamorphism and widespread deformation within the Moine[3–5,17]. Given that there is no indication of any major structural or metamorphic break of Precambrian age between the south-west Moine and Glenelg[18], it seems difficult to avoid the conclusion that the initial metamorphism of the Moine occurred at ~1,100–1,000 Myr BP.

SANDERS REPLIES—Strachan and Treloar favour contemporaneous (1,100–1,000 Myr BP) metamorphism for both the eclogite-bearing basement and the Moine cover in the Glenelg region. To sustain their view, they suggest that the ab normally high metamorphic pressure

(>12 kbar) inferred for the basement[1] is a serious overestimate.

Although published evidence relating to metamorphic pressure/temperature (P/T) conditions for the Glenelg eclogite may not be extensive, I contend that the rock and mineral analyses reported (Table 1, ref. 1) are more than sufficient to demonstrate a high-pressure origin. The two eclogite samples have tholeiitic chemistry and are plagioclase free, they are therefore true eclogites (rather than high-pressure granulites) and reference to Green and Ringwood's[2] eclogite field is therefore valid Moreover, omphacite coexists with quartz in S274 and the mole fraction of jadeite in the omphacite is 0.31 (calculated as Al(VI) minus Al(IV) in a 4-cation formula). Assuming a disordered pyroxene structure, the omphacite composition implies a pressure >15 kbar at 700°C (ref. 3). The temperature estimate of 700°C is, incidentally, supported by a large body of unpublished analytical data relating to garnet/clinopyroxene thermometry and calcite solvus thermometry

Against this P/T background, Strachan and Treloar's staurolite/quartz-bearing assemblage from the Glenelg basement may best be regarded as a product of the widespread retrogressive metamorphism that has affected the eclogite and other high-grade rocks at Glenelg[4] According to Strachan and Treloar, the staurolite/quartz-bearing assemblage is equivalent in terms of P/T conditions to the Moine Thus, it would seem that retrogression in the basement correlates with prograde metamorphism in the cover, which is, of course, consistent with the view that the Moines were deposited on an eroded Grenville basement. With regard to the Ardgour gneiss, I would argue that the case for intrusion at about 1,000 Myr BP is considerably weakened by the real possibility that the gneiss is a metasediment with a derived Rb/Sr isotope system.

In my view, any claim that the Moines have a Grenville metamorphic history carries with it the implication that they underwent early eclogite-facies metamorphism, at least in the Glenelg area. Hitherto, evidence for such an event has not been reported

Proper solar wind power estimation and planetary radiometric efficiencies

DESCH and Kaiser[1] have computed the average absolute efficiencies of the radio planets for electromagnetic wave production, restricting their attention to the emissions known to be controlled by solar wind energy inputs to the magnetospheres of the Earth, Jupiter and Saturn. Our purpose here is to offer a word of caution about the methods, assumptions and conclusions of their paper and to suggest that radio emissions for unexplored planets, such as Uranus, may be much different from what they determined.

Their method[1] was to compute the solar wind input power, P_i, to the various magnetospheres by estimating the solar wind kinetic energy flux (ρV^3) at the planetary location and to use the square of the Chapman–Ferraro length ($l_0 = (M^2/4\pi\rho V^2)^{1/6}$) as an estimate of the effective energy 'collection' area of the magnetosphere Here M is the planetary magnetic moment, ρ is the solar wind mass density (g cm^{-3}) and V is the solar wind speed, so that ρV^3 has units of erg cm^{-2} s^{-1} Then, using estimates of the planetary radio emission power, P_r (at a standard distance of 1 AU), the authors computed an efficiency, from the ratio P_r/P_i

The fault with this method is demonstrated in Fig. 1 Visual inspection of Fig. 1 shows that the AE index correlates quite well with the ε, or P_{VB_s}, parameter (correlation coefficient ~0.7), but the time profile of AE bears little specific relationship to the P_k parameter Detailed study has shown conclusively[2-4] that ρV^3, in the case of the Earth, is not the solar wind parameter that 'drives' auroral disturbances. The results shown in Fig 1 are quite general As AE is a measure of auroral activity and can be used[3] to estimate auroral particle precipitation and auroral Joule heating, we may conclude with confidence that P_k does not correlate well with these primary forms of terrestrial auroral energy dissipation Furthermore, as it is well known[5] and indeed implicit in the argument of Desch and Kaiser, that auroral kilometric radiation (AKR) is well correlated with AE, we may also conclude that P_k is not well correlated with AKR.

The reasoning is thus as follows. The quantity ρV^3 is poorly correlated (on substorm timescales) with VB^2 in the solar wind, but it is VB^2 (or a refinement thereof) which controls substorm (AE) activity at Earth Because it is clearly substorm activity, and collective plasma processes during substorms, that control the generation of AKR, solar wind estimates of ρV^3 are an improper estimate of P_i as a causal agent of AKR (or P_r), in the case of the Earth. By extension, the computed radiometric efficiency estimates[1] must be regarded as being predicated on erroneous assumptions.

Now Gallagher and D'Angelo have shown a very strong dependence of AKR on the solar wind speed only[6], but as they used very long-term averages, their results were strongly time aliased. Indeed, if one looks at long-term averages, geomagnetic activity is well correlated with the solar wind speed[4,7], but this says almost nothing about the solar wind–magnetosphere coupling mechanism or substorm energy source as substorms occur on timescales of $\lesssim$ 1 h.

The criticism raised here might be less significant if ρV^3 were of a similar magnitude as $VB^2/8\pi$, but it is almost always true that ρV^3 is ~100 times larger than $VB^2/8\pi$. This is well illustrated in Fig 1. Thus, as it is the electrostatic[4] or electromagnetic (Poynting)[3] energy in the solar wind which drives auroral activity, the values of efficiency derived by Desch and Kaiser should be ~100 times greater in the case of the Earth[8].

We really do not know how similar or dissimilar the generation of Saturn kilometric radiation (SKR) is to AKR Furthermore, we are uncertain of the generation mechanism of the hectometre-wavelength (HOM) emission of Jupiter. A further exacerbating feature is that we have little clear evidence as to whether solar wind–magnetosphere coupling proceeds by the same physical processes at Saturn and Jupiter as it does at the Earth If precisely the same processes were to occur (that is, dayside magnetic reconnection and magnetotail substorm initiation[8]), we would estimate that the SKR and HOM efficiencies should also be ~100 times greater than estimated by Desch and Kaiser. On the other hand, if solar wind kinetic energy flux variation were driving the HOM and/or SKR components, then the values of efficiency would be $\sim 5 \times 10^{-4}$ for the Earth, but would be only $\sim 5 \times 10^{-6}$ for Jupiter or Saturn (as estimated by Desch and Kaiser).

In conclusion, based on a proper computation of the energy entering the Earth's magnetosphere, we conclude that terrestrial AKR is produced with a much higher efficiency than computed by Desch and Kaiser. Similarly high efficiencies may or may not apply in the cases of Jupiter and Saturn, this depends very strongly on the physical processes responsible for solar wind–magnetosphere coupling in those cases Because of such uncertainties, the radiometric estimates made for Uranus[1] must be regarded with caution. In view of the 'pole-on' interaction of Uranus with the solar wind mentioned by Desch and Kaiser, the nature of solar wind coupling may be very different for any possible Uranus magnetosphere. At the very least, readers should appreciate that in the Earth's magnetosphere it is electromagnetic, not particle, energy in the solar wind that drives geomagnetic activity.

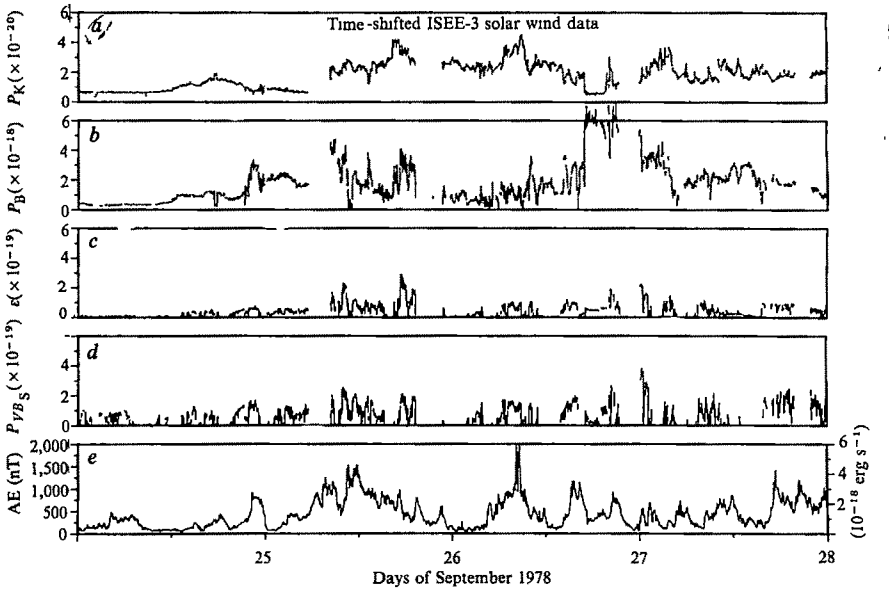

Fig. 1 *a–d*, Summaries of various power estimates (in erg s^{-1}) using data taken in September 1978 from the ISEE-3 spacecraft ~240 R_E from Earth in the upstream solar wind. These data have been time-shifted to account for propagation time delay to the Earth. *a*, P_K ($=\pi l_0^2 \rho V^3$) plotted for a several-day interval. *b*, The solar wind magnetic energy power P_B ($=\pi l_0^2 V(B^2/8\pi)$). *c*, *d*, Popular refinements of the magnetic energy power parameter: *c* shows ε ($=VB^2 \sin^4(\theta/2)(l_0^*)^2$, where $l_0^* = 7R_E$ and θ is the angle between the Earth's field and the interplanetary field; *d* shows VB_s ($=-B_z$ for negative IMF, and 0 for positive IMF) scaled to the Chapman-Ferrary interaction area. *e*, The Auroral electrojet[2] index, AE (scale to the left). Using empirical relationships[2,3] it is also possible to make magnetospheric energy dissipation estimates from AE (scale to the right).

DESCH AND KAISER REPLY—Baker and Bargatze have argued that high time resolution comparisons of auroral electrojet (AE) with the solar wind input lead to a much higher efficiency for the conversion of solar wind power into auroral kilometric radiation (AKR) than that estimated by us[1]. Therefore, if different efficiencies apply at Jupiter and Saturn, where physical processes are not as well understood, then our 'radiometric Bode's law' cannot be reliably extrapolated to the case of Uranus.

We agree that high time resolution studies have led to a better understanding of solar wind-magnetosphere coupling processes at the Earth than presently exists at either Jupiter or Saturn, but it is not clear that this understanding extends to solar wind-AKR coupling, nor is it apparent that conclusions drawn from longer-term averaging of the data are necessarily improper. Regarding the first point, Voots *et al.*[2] actually noted a rather small (51%) degree of correlation between AE and AKR, attributing this, in part, to the 'poor short timescale (< 1 h) correlation' that they observed. Thus, although the relationship between substorm activity (as indicated by AE) and the solar wind may be well understood, that between AKR power and the solar wind is not.

We used the solar wind kinetic energy flux, ρV^3 (where ρ is the solar wind mass density and V the solar wind speed), to characterize the energy input to each magnetosphere, because the radio emissions of the known radio planets show by far the best correlation with solar wind plasma properties, such as ρ or V, and little or no correlation with magnetic properties such as VB^2 (refs 3–5). For example, there is almost a one-to-one correspondence between the radio emission output of the AKR and the solar wind speed[3] and between the radio output of Saturn and the solar wind density[4]. Each of the studies of Desch and Kaiser has in common the consistent use of one-rotation-averaged solar wind and radio emission quantities. Certainly details of the interaction mechanism are lost when such long-term averages are used, but some coarse information about the interaction probably remains.

Our radiometric Bode's law is intended as a heuristic demonstration of one property of radio-emitting magnetospheres, namely, their gross radio efficiency. Whether or not this law reflects some underlying physical property of radio planets in general is not known; indeed it was not our intention to suggest that such a property exists. However, the potential predictive value of the proposed relationship is, we feel, of some interest and will be tested further by Voyager spacecraft observations of Uranus in the coming year.

Matters Arising

Matters Arising is meant as a vehicle for comment and discussion about papers that appear in *Nature*. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted. Neither contribution nor reply (if one is necessary) should be longer than 500 words and the briefest of replies, to the effect that a point is taken, should be considered.

Why this magazine and more than 1,000 others let us go over their books once a year.

Some magazines, we're sorry to say, keep their readers undercover. They steadfastly refuse to let BPA (Business Publications Audit of Circulation, Inc.) or any other independent, not-for-profit organization audit their circulation records.

On the other hand, over 1,000 publications (like this one) belong to BPA. Once a year, BPA auditors examine and verify the accuracy of our circulation records.

This audit provides the name, company, industry and job title of every reader each publication reaches. The information helps advertisers to determine if they are saying the right thing to the right people in the right place.

It also helps somebody else important: you. Because the more a publication and its advertisers know about you, the better they can provide you with articles and advertisements that meet your informational needs.

BPA. For readers it stands for meaningful information. For advertisers it stands for meaningful readers. Business Publications Audit of Circulation, Inc.

PLANT PHYSIOLOGIST
(5 year term appointment with the possibility of promotion to Staff Senior Scientist)

The Chemical Biodynamics Division is seeking a plant physiologist or biochemist to join and complement an existing program studying the organization and control of genes coding for photosynthetic components in plant cells. Responsibilities include organizing and operating a plant cell culture laboratory. This position requires experience in plant cell culture techniques, propagation of plants from protoplasts, and identification of plant gene products Prefer a PhD in related field.

Send two copies of your résumé to Lawrence Berkeley Laboratory, 1 Cyclotron Road, Employment Office 90-1042, Berkeley, CA 94720. An Equal Opportunity Employer M/F/H. Please specify Job No A/3367. (NW1694)A

CAMBRIDGESHIRE COLLEGE OF ARTS AND TECHNOLOGY
(equal opportunity employer)

DEPARTMENT OF SCIENCE

LECTURER I IN GEOLOGY
(Temporary)

Required for one year from 1st September 1985: The successful candidate will be required to teach Metamorphic Petrology and Tectonic Processes to final honours degree level. A strong interest in field-work is necessary. Other teaching will include map work and supervision of project students.

Salary Scale L1 £5,910 — £10,512 (award pending), starting point according to qualifications and experience

Details and forms, to be returned by 10th May, from Administrative Assistant, Department of Science, CCAT, East Road, Cambridge CB1 1PT, Tel. (0233) 352992. (6183)A

OXFORD UNIVERSITY
DEPARTMENT OF BOTANY

ELECTRON MICROSCOPE TECHNICIAL

Grade Three or Trainee Technician. Salary: £5,399 - £6,325. 00 or £3,173 -£4,462.00.

A vacancy exists for a Technician to work in the Electron Microscopy section of this Department. The position is open to both qualified Technicians and trainees. Grade 3 candidates should possess ONC or equivalent. Trainee candidates should have four GCE 'O' level (or CSE Grade 1) passes and be aged between 16 and 18.

Applications in writing, together with a Curriculum Vitae and the names and addresses of two referees to The Administrator, The Botany School, South Parks Road, Oxford OX1 3RA.

Closing date for applications: May 17th, 1985. (6235)A

Molecular and Cell Biology Research Overseas

Realize your full potential on multi-disciplinary projects within this well-equipped new laboratory.

An integral part of the CSIR located on the University of the Witwatersrand campus in central Johannesburg, the 15-month old Laboratory for Molecular and Cell Biology (LMCB) has a mandate to develop molecular and cell biology in biotechnologically-related areas throughout the Republic of South Africa

We currently seek experienced Scientists who, actively encouraged by Prof. Jennifer A Thomson, will develop independent research programmes and assist the LMCB in co-ordinating the activities of decentralized groups in other laboratories nationwide, thereby interacting on a regular basis with such diverse personnel as biochemists, immunologists, zoologists and botanists

In order to handle the high research and liaison responsibilities involved, applicants should be PhD graduates with research experience in at least one of the fields of recombinant DNA, microbial genetics, nucleic acid analyses, molecular or cell biology

Salaries, negotiable according to qualifications and experience, will be enhanced by generous benefits including a housing loan subsidy (where appropriate), an annual bonus medical aid, pension/life assurance schemes, plus comprehensive sports and recreational facilities. Additionally free air passages, assistance with removal costs and settling-in allowance will be provided

Johannesburg in turn will provide good educational facilities (primary school to polytechnic and university level), outstanding shopping and recreational amenities plus a year-round outdoor climate

For an application form, please ring 01-242 1766 during normal office hours or send a detailed CV including phone number to: The Scientific Counsellor, South African Science Office, 2nd Floor, Chichester House, 278 High Holborn, London WC1V 7HE, **quoting ref. 85/640/60 clearly on the envelope.** All interviews will be conducted soon

These vacancies are open to members of both sexes regardless of colour, race or creed.

CSIR

The CSIR is a statutory organisation that undertakes and supports research in various fields of Science and Technology — for the benefit of all peoples within the Republic of South Africa — through 5 000 staff and 30 institutes, laboratories and service departments nationwide

COUNCIL FOR SCIENTIFIC AND INDUSTRIAL RESEARCH

(NW1701)A

Melbourne, Australia

Post Doctoral Biochemist/ Cell Biologist

Receptor/Transport Studies

A position for a scientist with several years' post doctoral experience in field of membrane transport and/or in study of trace elements to work in group exploring the intracellular transport of copper and zinc, utilising human, mouse and dog mutations Applications from more junior post doctoral scientists will also be considered. The group already has a substantial reputation in this subject, but wishes to increase its efforts substantially

The Birth Defects Research Institute is entering a phase of rapid expansion with private and government support and its staff includes scientists spanning the whole field of birth defects and genetics from the DNA level to clinical diagnosis and treatment Unique opportunities exist for research into the basic scientific issues underlying human genetic diseases, with the advantage of new ideas flowing from practical involvement with patients

The Parkville/Carlton region of Melbourne houses the greatest concentration of biomedical research institutes in Australia — the Walter and Eliza Hall Institute, the Howard Florey Institute, the Ludwig Institute, the CSIRO Division of Animal Science and Protein Chemistry, and the University of Melbourne campus are all within walking distance of the Institute's modern and well-equipped laboratories.

Salaries in line with University and NH and MRC scales. An initial appointment for two or three years is contemplated, with opportunities for on-going career based on five-year periods of appointment. Assistance with removal costs may be negotiable.

Inquiries and applications to Professor D. M Danks, Director, Birth Defects Research Institute, Royal Children's Hospital, Flemington Road, Parkville, Vic. 3052, Australia. Telephone (03) 345-5044

(W1816)

BOOKER HEALTH FOODS LIMITED

TECHNICAL DEVELOPMENT MANAGER

Booker Health Products, the leading health products company in the country, is involved in the manufacture, marketing, selling and distribution of a wide range of quality health products.

As part of the company's expansion programme, we are currently looking for a TECHNICAL DEVELOPMENT MANAGER to work in West Byfleet, Surrey. Reporting to the Technical Director, the successful candidate will assist in the conception, development and technical specification of new products for Booker Health Products for both the UK and overseas markets.

The ideal candidate will be an honours graduate in biochemistry, nutrition or food sciences with at least two years commercial experience. Good analytical and communication skills are essential. A competitive salary, 22 days holiday and all large company benefits are offered.

Please contact for further details or application form or send CV to John Hughes, Personnel Manager, Booker Health Foods Ltd., Healthways House, 45, Station Approach, West Byfleet, Surrey. Telephone Byfleet 41133 ext 129. (6217)A

Royal Postgraduate Medical School

(University of London)

The following vacancies exist in the School's

DEPARTMENT OF VIROLOGY

Senior Technician (Ref: N10/01)

A Senior Technician is required in a newly established laboratory working on oncogenic and cellular transformation. The person appointed will act as research assistant to the Head of Department and be part of a small but active group studying DNA viruses. For the right applicant, some independent work would be encouraged. Experience in various aspects of protein biochemistry, molecular and cellular biology would be an advantage.
Salary will depend upon qualifications and experience.

Technician (Ref: N10/02)

Technician required for a 5 year post to work with a team of scientists on the immunology of Epstein-Barr virus infection. The successful applicant will carry out routine tissue culture as well as molecular biological techniques.

Post-doctoral Scientist (ref: N10/03) and Technician (ref: N10/04)

required to undertake a 3 year MRC funded project on the production of human monoclonal antibodies to viral antigens using EB virus transformation of B lymphocytes. The successful applicants will join a team of scientists studying EB virus/B cell interactions and will have the opportunity to learn both cellular and molecular biological techniques of B cell transformation.

Salaries: Technician scale: £5,795 — £8,177 plus £1,084 London Allownce pa. Post-doctoral Scientist, Scale 1A, from £7,520 plus £1,233 London Allowance pa.

Application forms may be obtained from the Personnel Office, RPMS, 150 Ducane Rd. W12 0HS. Please ensure the post reference number is quoted.

Closing Date: 23 May 1985. (6220)A

SCIENTIST

A position is currently available in our Cambridge facility for a scientist with expertise and skills in the specialty area of

IMMUNOLOGY

You will be part of a staff responsible for immunoassay development, antibody production and hybridoma work within the research and development group. In addition, you will contribute to immunological research (functional studies, animal models) on our Cambridge projects.

The successful candidate will possess a Ph.D. with postdoctoral experience in immunology. Skills in the areas of general immunochemistry, assay development and hybridoma production are required.

Biogen is an international biotechnology company engaged in the development of commercial products through the use of advanced biological science, particularly recombinant DNA and advanced mutational techniques. We offer a challenging scientific career with the opportunity to interact with talented colleagues in a stimulating environment.

Biogen offers an excellent compensation and benefits package.

Please forward your C.V. and the names of three references to: Ms. Nanci Pye, Manager of Human Resources, Dept. S-14, Biogen, 14 Cambridge Center, Cambridge, MA 02142. An equal opportunity employer.

BIOGEN

RESEARCH SCIENTIST

The Massachusetts Institute of Technology (MIT), Whitaker College of Health Sciences, Technology and Management, announces an opening for a Research Scientist to work within the Center for Biological Information Processing integrating theoretical and experimental brain sciences. Responsibilities will include developing computer models of single neurons, dendritic trees and synapses from physiological and anatomical data, as well as interaction with visual psychophysics and the computational theories of vision. He or she will also explore computational properties of biophysical mechanisms and will apply these results to the analysis of the neural circuitries involved in the perception of motion and stereo

A Ph.D. in mathematics, physics or computer science is required. Experience in how computational theories can be implemented in algorithms, and how the underlying biophysical hardware can determine the nature of the algorithm is also required. A solid background in mathematics, knowledge of invertebrate and vertebrate biophysics, physiology and extensive computer experience is expected. LISP computer language desirable.

Interested applicants should send two copies of cover letter and curriculum vitae, as well as any relevant publications to: Dr. Tomaso Poggio, c/o MIT Personnel Office (E19-239), 77 Massachusetts Avenue, Cambridge, MA 02139. Reference Job #R84-573. MIT is an Affirmative Action/Equal Opportunity Employer.

Qualified minorities and women are encouraged to apply.

(NW1695)A

MIT

PLANT BREEDING INSTITUTE

Applications are invited for the following positions to work for a period of three years with a large, well-established team of molecular geneticists under the leadership of Dr R B Flavell:

1. POSTDOCTORAL FELLOW to further understanding of photosynthesis and chloroplast biochemistry by the insertion of new enzymes and genes into the chloroplasts of whole plants. The project involves the isolation, characterisation and reconstruction of genes, their insertion into plants using *Agrobacterium* vectors and plant tissue culture and biochemical and physiological assessments of the altered plants.
Candidates should have a first or upper second class honours degree in an appropriate biological subject with at least two years' experience in biochemistry or molecular biology, and a PhD. **Ref: CYT/205.**

2. SCIENTIFIC OFFICER to assist as above.
Candidates should have a first or upper second class honours degree in an appropriate biological subject. Experience in biochemistry or molecular biology would be an advantage. **Ref: CYT/206.**

3. POSTDOCTORAL FELLOW to develop transposable element genetics in specific dicot plants. The approach will include the insertion of already defined transposable elements from other species into the dicot crop species using *Agrobacterium* vectors and tissue culture. The project will exploit many of the techniques of molecular biology.
Candidates should have a first or upper second class honours degree in an appropriate biological subject with at least two years' experience in biochemistry, genetics or molecular biology, and a PhD. **Ref: CYT/207.**

4. SCIENTIFIC OFFICER to assist as above.
Candidates should have a first or upper second class honours degree in an appropriate biological subject. Experience in biochemistry, genetics or molecular biology would be an advantage. **Ref: CYT/208.**

Appointment for the Postdoctoral positions will be at Higher Scientific Officer (£7,435 to £10,039 pa), and at Scientific Officer for positions (2) and (4) (£5,909 to £8,153 pa). A non-contributory pension scheme is in operation.

Applications with curriculum vitae and names and addresses of three referees for the HSO grade and two for the SO grade should be sent to the Establishment Officer, Plant Breeding Institute, Maris Lane, Trumpington, Cambridge CB2 2LQ, *quoting the appropriate reference number,* by 23 May 1985.

The Institute is an Equal Opportunities Employer. (6241)A

QUEENSLAND INSTITUTE OF MEDICAL RESEARCH POSITIONS IN MOLECULAR BIOLOGY

The Queensland Institute of Medical Research, affiliated with the University of Queensland, is a major Australian Medical Research Centre It is situated on the medical campus of the University in association with the Royal Brisbane Hospitals complex. Research is broadly based in cancer and cell biology, molecular biology and parasitology, virology and immunology, epidemiology and public health There are extnesive national and international collaborative programmes.

The Institute is expanding its existing base in molecular biology, particularly in the recombinant DNA unit. Present work includes molecular mechanisms of genetic arrangement relating to gene activation, expression and transposition in eukaryotes, human gene isolation/structure, viral gene structure/control, parasite gene structural organization, together with special programmes directed to vaccine development against malaria parasites and dengue viruses. This expansion is made possible by new laboratory space and equipment.

Applications are called for two positions·

1. Molecular biologist/biochemist to work as a senior member of the recombinant DNA unit, contributing to ongoing programmes from a base of fundamental cloning and related techniques. The applicant would be encouraged to sustain independent research in this area. This position is funded from established (trust) funds, with salary according to qualifications and experience, in the range 24,840 to 38,847 Aust dollars p.a. Appointment will be for 5 years initially, but renewable.

2. Biochemist/Geneticist to work with the recombinant DNA unit and the human genetics laboratory, with particular reference to human gene isolation/structure, recombination mechanisms and their control in eukaryotes. The position is funded by a block grant from the Australian National Health and Medical Research Council, with salary according to qualifications and experience, in the range 21,411 to 32,634 Aust dollars p.a. Appointment will be up to 5 years.

Applicants should forward a full curriculum vitae, together with an outline of research interests with names and addresses of 3 referees to:

The Director
Queensland Institute of Medical Research
Bramston Terrace
Herston
Brisbane 4006 Australia
Phone: (07) 2536202
Telex: QIMRBR 145420

Applications close on 1 June, 1985. (W1822)A

UNIVERSITY OF CAPE TOWN

ASSOCIATE PROFESSOR/SENIOR LECTURER/ LECTURER IN BIOCHEMISTRY (MOLECULAR GENETICS AND MOLECULAR BIOLOGY)

Applications are invited for the above posts in the Department of Biochemistry. Candidates should have strong research interest and achievements in eucaryotic molecular genetics and experience in recombinant DNA technology Alternatively, candidates experienced in the field of structural investigation on proteins and protein-nucleic acid complexes will be considered. The posts may also be filled at the request of the applicant on a contractual basis for 2-3 years with either the possibility of renewal or conversion into a tenured post. Appointments according to qualifications and experience will be made on the salary scales:

Associate Professor	—	R28 889 - R35 377 p.a.
Senior Lecturer	—	R26 403 - R32 763 p.a.
Lecturer	—	R17 267 - R28 889 p.a.

with an annual bonus and attractive staff benefits.

Applicants should submit a full curriculum vitae, including the names and addresses of three referees not later than 7 June 1985, to the Registrar (Attention Appointments Office Ref. AC/5412) University of Cape Town, Rondebosch, 7700, South Africa Further information may be obtained from the Registrar or The Secretary, SA Universities Office, Chichester House, 278 High Holborn, London WC1V 7HE. The University's policy is not to discriminate on the grounds of sex, race or religion Further information on the implementation of this policy is obtainable on request. (W1812)A

INSTITUTE OF TERRESTRIAL ECOLOGY

RADIOCHEMIST

A radiochemist is needed to join a small team, looking into the distribution of radionuclides in the environment. The appointee will be based at the Institute's Merlewood Research Station, Grange-Over-Sands, Cumbria.

Qualifications and Experience: The minimum qualification for the post is a good degree or equivalent. Previous experience is desirable.

Salary: The appointment will be to Higher Scientific Officer/Senior Scientific Officer grade with a salary scale of £7,435 - £10,039 pa for HSO or £9,329 - £12,050 pa for SSO. Starting salary will be according to age, qualifications and experience.

The Natural Environment Research Council is not a government department but conditions of service are similar to those of the Civil Service.

Application forms and further details are available from: Institute of Terrestrial Ecology, Administrative Headquarters, Monks Wood Experimental Station, Abbots Ripton, Huntingdon PE17 2LS Telephone 04873 381-8.

Please quote reference number: 229.

The closing date for applications is 9 May 1985.
